UNIVERSAL DICTIONARY

OF

ARTS and SCIENCES.

REPUBLIC.

REPUBLIC, Respublica, *commonwealth*, a popular ſtate or government; or a nation where the body, or only a part of the people, have the government in their own hands.

When the body of the people is poſſeſſed of the ſupreme power, this is called a *democracy*. When the ſupreme power is lodged in the hands of a part of the people, it is then an *ariſtocracy*. See Aristocracy and Democracy.

The celebrated republics of antiquity are thoſe of Athens, Sparta, Rome, and Carthage. At preſent, there is ſcarcely any ſuch thing as a real republic, *i.e.* a ſtrictly popular ſtate. Indeed, the Venetians and Genoeſe have called their ſtates republics; but their government was apparently *oligarchic*.

The Dutch, in their former ſtate, came the neareſt to the character of a republic; yet they were very defective, at leaſt in the ſenſe and ſeverity with which Rome, Carthage, &c. were republics. See States-*General*.

It is a remark of M. St. Evremont, that if the Dutch love the republican form, it is more for the ſake of their trade than of their liberty.

Holland, which was compoſed of about fifty republics, all different from one another, might be conſidered as a confederate republic; or a convention by which ſeveral petty ſtates agree to become members of a larger one, which they intend to eſtabliſh. When ſeveral ſovereign and independent ſtates unite themſelves together by a perpetual confederacy, whilſt each of them continues to be a perfect ſtate, they will form together a federal republic: the deliberations in common will offer no violence to the ſovereignty of each member, though they may, in certain reſpects, put ſome conſtraint on the exerciſe of it, in virtue of voluntary engagements. A perſon does not ceaſe to be free and independent when he is obliged to fulfil the engagements into which he has very willingly entered. In this view, Germany, which conſiſted of free cities, and of petty ſtates, ſubject to different princes, and the Swiſs cantons, were conſidered in Europe as perpetual republics.

Of this kind were formerly the cities of Greece; and in later times were the ſeven United Provinces of the Netherlands; and ſuch, as we have juſt ſaid, were the members of the Helvetic body. To this claſs we may likewiſe refer the federal government of the United States of America. See Government.

Baron de Monteſquieu, in his "Spirit of Laws," enumerates the following diſtinctive properties of a republic. It ſhould have a ſmall territory; otherwiſe it cannot long ſubſiſt. In a large republic there are men of large fortunes, and conſequently of leſs moderation; there are too great depoſits to intruſt into the hands of a ſingle ſubject; intereſts are divided; an ambitious perſon ſoon becomes ſenſible that he may be happy, great, and glorious, by oppreſſing his fellow-citizens; and that he might raiſe himſelf to grandeur on the ruins of his country.

In a large republic, the public good is ſacrificed to a thouſand views; it is ſubordinate to exceptions; and depends on accidents. In a ſmall one, the intereſt of the public is eaſier perceived, better underſtood, and more within the reach of every citizen; abuſes have a leſſer extent, and of courſe are leſs protected.

The long duration of the republic of Sparta was owing to its having always continued with the ſame extent of territory after all its wars. The ſole aim of Sparta was liberty; and the ſole advantage of its liberty, glory.

It was the ſpirit of the Greek republics to be as contented with their territories, as with their laws. Athens was firſt fired with ambition, and gave it to Lacedæmon; but it was an ambition rather of commanding a free people, than of governing

governing ſlaves; rather of directing than of breaking the union. All was loſt upon the ſtarting up of monarchy, a government whoſe ſpirit is more turned to increaſe and advancement.

Excepting particular circumſtances, as when a petty ſovereign ſupports himſelf betwixt two great powers by means of their mutual jealouſy, it is difficult for any other than a republican government to ſubſiſt long in a ſingle town. A prince of ſo petty a ſtate would naturally endeavour to oppreſs, becauſe his power would be great, while the means of enjoying it, or of cauſing it to be reſpected, would be very inconſiderable. The conſequence of this would be, that he would trample upon his people. On the other hand, ſuch a prince might be eaſily cruſhed by a foreign, or even a domeſtic force; the people might every inſtant unite and riſe up againſt him. Now, as ſoon as a prince of a ſingle town is expelled, the quarrel is over; but if he has many towns, it only begins.

Republic *of Letters*, is a phraſe uſed in ſpeaking collectively of the whole body of the people of ſtudy and learning.

There is a journal, begun in Holland, by M. Bayle, and continued by M. Bernard, conſiſting of extracts of books, printed in the courſe of the year, called "Nouvelles de la Republique des Lettres," News from the Republic of Letters. See Journal.

REPUBLICATION *of a Will*. See Will.

REPUDIATION, Repudium, in the *Civil Law*, the act of divorcing. See Divorce.

REPULSE Bay, in *Geography*, a bay on the N.E. coaſt of New Holland, in the South Pacific ocean. S. lat. 20° 36'. W. long. 148° 33'.—Alſo, a bay on the coaſt of Kerguelen's land.—Alſo, a bay on the W. coaſt of America. N. lat. 66° 40'. W. long. 85°.

REPULSION, Repulsio, in *Phyſics*, the act of a repelling power, by which bodies, under certain circumſtances, naturally fly from each other.

Repulſion is the counter part to *attraction*. Attraction only reaches to a little diſtance; where that terminates, there repulſion commences. See Air and Compression.

Indeed, we meet with many obvious inſtances of repulſion among bodies, as between water and oil, and, in general, between water and all unctuous bodies; between mercury and iron, as alſo between the particles of duſt, &c.

Thus, if a fat body, lighter than water, be laid on the ſurface of it, or if a piece of iron be laid on mercury, the ſurface of the fluid will be depreſſed about the bodies laid on it. This is a plain indication of repulſion; as the riſing up of the fluid about the ſurfaces of other incumbent bodies is of attraction.

In the latter caſe, the fluid is ſuſpended, by an attractive power, above the level, and kept from falling by its gravity: in the former, a depreſſion is made by the repelling power, which the liquor, notwithſtanding its gravity, cannot run down into, and fill up.

Upon this depend all the phenomena of very light glaſs bubbles floating on water, about which, when clean, the water riſes; but when greaſed, the water ſinks into a channel all around them. Hence alſo it is, that in a glaſs-veſſel of water, the fluid ſtands higher all about the edges near the glaſs than towards the middle; but when the glaſs is filled till the water run down on all ſides, then it ſtands higher at the middle than at the ſides. Hence, alſo, in a glaſs not full of water, a clean glaſs bubble always runs to the ſide, by reaſon the preſſure, which is upon it towards the middle, is partly taken off by the attractive force with which the water is raiſed near the edge. If the glaſs be ſo full as to be ready to run over, the bubble returns from the ſide towards the middle, the force with which the water is raiſed in the middle taking off part of the preſſure.

Juſt the reverſe happens if the bubble be greaſy; becauſe there the force, by which the water and the bubble repel each other, is greateſt where the water is higheſt. Two clean bubbles and two greaſy ones always run towards each other, as being attracted; and a greaſy and a clean one always fly each other, as being repelled.

REPUTATION, *Injuries affecting*. See Injury.

REQUENA, in *Geography*, a town of Spain, in New Caſtile, ſeated on the top of a hill, near the Oliana, on the borders of Valencia. Bourgoanne, a modern traveller, ſays, that wealth and activity proclaim in this place the preſence of induſtry, and accordingly the number of ſilk looms amounts to 900. It has been ſuppoſed to be the Salaria, placed by Ptolemy in the country of the Baſtitani; 55 miles S.E. of Cuença.

REQUEST, in *Law*, a ſupplication or petition preferred to a prince, or court of juſtice, begging relief in ſome conſcionable caſes, where the common law grants no immediate redreſs.

The term requeſt is now, ſince the inſtitution of chancery, much diſuſed; together with the court of requeſts, where requeſts were cognizable.

In the old government of France, *requêtes civiles*, civil requeſts, obtained for the annulling of contracts, &c. made by ſurprize.

They had eighty maſters of requeſts to take cognizance of cauſes between the officers of the crown, the ſervants of the houſehold, &c.

Requests, *Court of*. See Court *of Requeſts*, and Court *of Conſcience*.

Request, in *Hunting*, is when the dogs have loſt the *queſt* or tract of the beaſt, and muſt *requeſt*, or *queſt* it again. They ſay, *to call to the requeſt*, *come to the requeſt*, &c.

To requeſt the game is chiefly uſed, when, after having run it down the night before, they ſeek it again the next morning with the blood-hound, or the like.

REQUEURIA, in *Botany*, a genus named in the Flora Peruviana, page 16, after Louis Requeur, a Spaniard, who was apothecary to king Philip V. *De Theis*. We are unacquainted with the plant, as well as with the botanical merits of the perſon to whom it is dedicated.

REQUIEM, a maſs ſung in the Romiſh church for the reſt of the ſoul of a perſon deceaſed.

It is thus called, becauſe the introit begins with "Requiem æternam dona eis, Domine," &c.

REQUINY, in *Geography*, a town of France, in the department of the Morbihan; 6 miles N.W. of Joſſelin.

REQUISTA, a town of France, in the department of the Aveiron; 18 miles S. of Rhodez.

RERE County. See Rier *County*.

Rere *Fiefs*, a name given in the Scotch laws to thoſe fiefs which were held by inferior tenants or feudatories, that cultivated the lands under the chief feudatories, who held by military ſervice.

Rere *Ward*, *arriere-garde*. See Rear, and Guard.

REREDOS, the ſkreen at the back of an ancient high altar, which ſeparated it from the Lady-chapel, being, for the moſt part, highly ornamented with niches, canopies, and tracery work. The richeſt of theſe which have reached our time are thoſe of Wincheſter and Durham cathedrals, and of St. Alban's abbey.

RERHUTTAN, in *Geography*, a town of Sweden, in Dalecarlia; 30 miles S.W. of Geffle.

RERIGONIAN Bay, in *Ancient Geography*, a bay on the northern side of ancient Britain, now Loch-rain, formed by the Mull of Galloway.

RERIGONIUM, called by some *Berigonium*, a town of the Novantæ, situated somewhere in Galloway, according to Camden the present Bargeny in Carrict; but Horsley prefers Barton or Strathaven.

RERONE, in *Geography*, a river of Italy, which rises in the Vicentin, and runs into the Brenta.

RERRE, a river of France, which runs into the Saudre, about a league above Romorantin.

RES, *Thing*. See Reality, Ens, Esse, Substance, &c.

Res *Mancipi*. See Abalienation.

Res *Naturales*. See Naturals.

Res *Non Naturales*, &c. See Non-*naturals*, &c.

RESAFA, in *Ancient Geography*, a town of Asia, on the W. side of the Euphrates.

RESAIA, a town of Mesopotamia, in Osrhoené.

RESAINA, or Theodosiopolis, *Ras-vin*, or *Ain-verdah*, a town of Mesopotamia, upon the banks of the river Chabotas. This town was famous on account of the victory obtained over Sapor by the younger Gordian, in the year 243. Under the empire of Severus, it was elevated to the dignity of a colony; and under Theodosius it assumed the name of Theodosiopolis.

RESAPHE, a town of Palmyrene, according to Ptolemy; but Procopius called it Sergiopolis. It was at some distance from the Euphrates.

RESAU or Rehau, in *Geography*, a town of Germany, in the principality of Culmbach; 7 miles E.S.E. of Hoff.

RESAVA, a river of Servia, which runs into the Passarovitz.

RESCEIT, Receptio, in *Law*, an admission or receiving of a third person to plead his right, in a cause formerly commenced between other two.

As, when an action is brought against a tenant for life or years, and he makes default; in such case he in the reversion may come in and pray to be received, to defend the land, and to plead with the demandant.

Resceit is also sometimes applied to an admittance of plea, though the controversy be only between two. He in reversion may come into court, and pray to be received in a suit against his particular tenant.

Resceit *of homage, receptio homagii*, denotes the lord's receiving homage of his tenant, at his admission to the lands.

RESCHOUET, in *Geography*, a town of Prussia, in Pomerelia; 7 miles N.N.E. of Zarnowitz.

RESCIPHA, in *Ancient Geography*, a place of Mesopotamia, on the banks of the Euphrates; situated S. of Corsote, and near to it.

RESCISSION, Rescissio, formed of *re*, and *scindo*, q. d. *I cut* or *divide again*, in the *Civil Law*, an action intended for the annulling or setting aside of any deed, contract, or the like.

A thing's being found damaged, or sold at above double the just value, is a good cause of rescission.

The deed or contract thus annulled, or rescinded, is sometimes called a *rescissory*; though that denomination be more properly given to the action brought for rescinding or setting it aside; which is properly called *actio rescissoria*.

RESCOUS, or Rescue, *Rescussus*, in *Law*, an illegal taking away, and setting at liberty, a distress taken, or a person arrested, by process, or course of law. This is properly a *rescous in fact*. If one distrain beasts for damage feasant in his ground, and as he drives them along the highway towards the pound, they enter into the owner's house, and he withholds them there, and will not deliver them upon demand; this detainer is a *rescous in law*. For a rescous, or the taking of goods by force, when, in a distress, they are in the custody of the law, which is considered as an atrocious injury, the distreiner has a remedy in damages, either by writ of *rescous* (F. N. B. 101.), in case they were going to the pound, or by writ *de parco fracto*, or pound-breach (ibid. 100.) in case they were actually impounded. He may also at his option bring an action on the case for this injury, and shall therein, if the distress were taken for rent, recover treble damages. (Stat. 2 W. & M. sess. 1. c. 5.) In case of the forcible delivery of a person arrested from the officer who is taking him to prison, the plaintiff has a similar remedy by action on the case, or of rescous (6 Mod. 201.); or, if the sheriff makes a return to such rescous to the court out of which the process issued, the rescuer will be punished by attachment. Cro. Jac. 419. Salk. 586. See Rescue.

He that commits a rescue or rescous, is called the *rescussor*.

Rescous is also used for a writ which lies for this fact, called *breve de rescussu*.

RESCRIPT, Rescriptum, an answer delivered by an emperor, or a pope, when consulted by particular persons, on some difficult question or point of law, to serve as a decision of it.

The civil and canon laws are full of such rescripts.

When the rescript was made in answer to the enquiry of a community, it was called a *pragmatic sanction*.

The papal rescripts are a kind of bulls or monitories, beginning with these words, "Significabit nobis dilectus filius," &c. They never obtained either in England or France, when contrary to the liberties of the English and Gallican churches; but were declared abusive.

Among the Romans the contending parties and even the magistrates themselves, frequently consulted the emperor on the measures they were to take in certain and nice difficult cases; and the answers returned by the emperor on such consultations, were called *rescripts*. These had not, indeed, the full force of laws; but they were deemed a strong prejudice or presumption: and in succeeding ages, they had the force of perpetual laws, though they ought to be carefully distinguished, by every rational civilian, from those general constitutions which had only the nature of things for their guides.

Justinian has inserted a great number of them in the Code; and by that means given them the authority they before wanted.

The author of the life of the emperor Macrinus observes of that prince, that he would have his officers judge by laws, not by rescripts; as esteeming it absurd to admit the wills of ignorant men, such as Commodus and Caracalla, for rules of judging; and because Trajan never gave any rescripts at all, as being loth to countenance a custom, where what is frequently granted as a favour, in particular cases, might be afterwards pleaded as a precedent. It is added, that Macrinus had a design to strip the rescripts of all their authority.

M. Schulting, in his Dissertations, does not at all approve of this design; and to the emperor's reasons answers, that indeed all rescripts are not to be admitted; that those which appear dictated out of favour, are to be thrown aside; but those which appear founded in reason, and natural equity, are, with Justinian, to be allowed. He adds, that it cannot be denied but the worst emperors have frequently made good laws, and useful rescripts.

As to what is urged of the emperor Trajan's never giving any rescripts, it appears but ill supported. For what is it but a rescript that he delivers to Pliny on the subject of the Christians, lib. x. epist. 28? Or that on the Isclastici, lib. x. epist. 120? The Digest, and Pliny's Epistles, need

only

only to be opened and compared, to find refcripts of Trajan. The refcripts of the emperor, his grants and decrees, his edicts and pragmatic fanctions, were fubfcribed in purple ink, or a compound of vermilion and cinnabar; and tranfmitted to the provinces as general or fpecial laws, which the magiftrates were bound to execute, and the people to obey. But as their number continually multiplied, the rule of obedience became each day more doubtful and obfcure, till the will of the fovereign was fixed and afcertained in the Gregorian, Hermogenian, and the Theodofian codes.

RESCUE. See RESCOUS. See alfo DISTRESS, and DISSEISIN.

RESCUE is one of thofe offences againft public juftice, which confifts in the forcibly and knowingly freeing another from an arreft or imprifonment; and it is generally the fame offence in the ftranger fo refcuing, as it would have been in a gaoler to have *voluntarily* permitted an efcape. A refcue, therefore, of one apprehended for felony, is felony; for treafon, treafon; and for a mifdemefnor, a mifdemefnor alfo. But here likewife, as upon voluntary efcapes, the principal muft firft be attainted, or receive judgment before the refcuer can be punifhed: and for the fame reafon; becaufe perhaps in fact it may turn out that there has been no offence committed. By ftatute 11 Geo. II. c. 26. and 24 Geo. II. c. 40. if five or more perfons affemble to refcue any retailers of fpirituous liquors, or to affault the informers againft them, it is felony, and fubject to tranfportation for feven years. By the ftatute 16 Geo. II. c. 31, to convey to any prifoner in cuftody for treafon or felony any arms, inftruments of efcape, or difguife, without the knowledge of the gaoler, though no efcape be attempted, or any way to affift fuch prifoner to attempt an efcape, though no efcape be actually made, is felony, and fubjects the offender to tranfportation for feven years: or if the prifoner be in cuftody for petit larceny, or other inferior offence, or charged with a debt of 100*l.*, it is then a mifdemefnor, punifhable with fine and imprifonment. And by feveral fpecial ftatutes, to refcue, or attempt to refcue, any perfon committed for the offences enumerated in thofe acts, is felony without benefit of clergy; and to refcue, or attempt to refcue, the body of a felon executed for murder, is fingle felony, and fubject to tranfportation for feven years. Nay, even if any perfon be charged with any of the offences againft the black act, 9 Geo. I. c. 22, and, being required by order of the privy council to furrender himfelf, neglects fo to do for forty days, both he and all that knowingly conceal, aid, abet, or fuccour him, are felons without benefit of clergy. See CONTEMPT.

RESCUSSOR, in *Law*. See RESCOUS.

RESA, or REZE, in *Geography*, a town of France, which runs into the Saudre, at Romorantin.

RESEARCH, formed of the French, *recherche*, and literally denoting a *fecond fearch*, a diligent fearch or enquiry into any thing.

RESEARCH, in *Mufic*, is a kind of prelude or voluntary played on the organ, harpfichord, violin, &c. in which the compofer feems to *fearch* or look out for the ftrains and touches of harmony, which he is to ufe in the regular piece to be played afterwards.

This is ufually done off-hand; and confequently it requires a mafter's fkill. When in a motetto, the compofer takes the liberty to ufe any thing that comes into his head, without applying any words to it, or fubjecting himfelf to the fenfe or paffion of it, the Italians call it *fantafia ricercata*, the French *recherche*, and the Englifh *refearch* and *voluntary*.

RESEARCHING, in *Sculpture*, the repairing of a caft, figure, &c. with proper tools; or the finifhing it with art and exactnefs, fo as that the minuteft parts may be well defined.

RESEDA, in *Botany*, a name which occurs in Pliny, and is evidently derived from *resēdo*, to allay or mitigate; fo that the fecond fyllable, vulgarly pronounced fhort, ought to be long. Pliny reports that this herb is known in the neighbourhood of Rimini, and is ufed for difperfing tumours, and all kinds of inflammations. The perfon who applies the medicine, fays "Refeda allay thefe difeafes," repeating thefe words, with fome others, and fpitting as often. After this account, the reader may not be anxious to know what Pliny's *Refeda* was. We have certainly no more reafon to believe it the fame as our's, than we have to rely on his fapient prefcription.—Linn. Gen. 242. Schreb. 326. Willd. Sp. Pl. v. 2. 876. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 512. Prodr. Fl. Græc. Sibth. v. 1. 322. Ait. Hort. Kew. v. 3. 153. Juff. 245. Tourn. t. 238. Lamarck Illuftr. t. 410. Gærtn. t. 76. (Luteola; Tourn. t. 238. Sefamoides; Tourn. t. 238.)—Clafs and order, *Dodecandria Trigynia*. Nat. Ord. *Mifcellaneæ*, Linn. *Capparides*, Juff.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, deeply divided into narrow, erect, permanent fegments, two of which are further afunder than the reft, for the accommodation of the honey-bearing petal. *Cor.* Petals feveral, unequal; fome of them always cut half way down into three fegments; the upper one gibbous at the bafe, bearing honey, the length of the calyx. Nectary a flat erect gland, proceeding from the receptacle, fituated at the upper fide of the flower, between the ftamens and uppermoft petal, converging with the dilated bafe of the petals. *Stam.* Filaments eleven or fifteen, fhort; anthers erect, obtufe, the length of the corolla. *Pift.* Germen gibbous, ending in three or four very fhort ftyles; ftigmas fimple. *Peric.* Capfule gibbous, angular, coriaceous, tipped with the ftyles, and gaping at the fummit between them, of one cell. *Seeds* numerous, kidney-fhaped, inferted into the angles of the capfule.

Obf. Linnæus obferves, that there is fcarcely any genus whofe character is more difficult to determine, both the number and fhape of the parts being different in different fpecies. The effential character confifts in the three-cleft petals, one petal bearing honey at its bafe, and the capfule not being clofed, but always gaping.

R. Luteola has the *perianth* in four deep fegments; *petals* three, the upper, or honey-bearing one, cut half way down into fix fegments; the lateral ones oppofite, three-cleft; to which are often fubjoined, by nature or luxuriance, two more, very fmall, undivided petals; the *ftyles* are three: *ftamens* numerous.

R. alba has fix deep fegments in the *perianth*: *petals* fix, nearly equal, all of them half three-cleft; *ftyles* four; *capfule* with four angles; *ftamens* conftantly eleven.

Some other fpecies have a deeply five-cleft *perianth*; five diffimilar three-cleft *petals*; *ftyles* three; *ftamens* numerous.

Eff. Ch. Calyx of one leaf, deeply divided. Petals laciniated. Capfule fuperior, gaping at the top, of one cell, with many feeds.

1. R. *Luteola*. Dyer's-weed, Yellow-weed, or Weld. Linn. Sp. Pl. 643. Willd. n. 1. Ait. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 320. Mart. Ruft. t. 40. (Luteola; Ger. Em. 494. Pfeudoftruthium; Matth. Valgr. v. 2. 643.)—Leaves lanceolate, undivided, flat. Calyx four-cleft.—Native of wafte ground, rubbifh, banks, and old walls, chiefly about villages, in moft of the temperate parts of Europe. About Norwich it is very common; partly perhaps from the difperfion of its feeds, in confequence of the great ufe made of the cultivated herb, in the woollen manufactory of that city, for dyeing yellow. The colour it affords is very bright, and is efpecially ufeful for making a good

a good green; the cloth being first dyed blue. The *herb* is annual, flowering in July. *Root* spindle-shaped. *Stem* erect, wand-like, two or three feet high, branched, leafy, striated, smooth. *Leaves* linear-lanceolate, entire, smooth, for the most part furnished with a small callous tooth, on each side, at the base. *Flowers* small, cream-coloured, very numerous, in long, simple, solitary, terminal, slightly drooping *spikes*, which, according to Linnæus, follow the course of the sun, even in a cloudy day—

> "True, as the dial, to the sun,
> Although it be not shined upon."

2. R. *canescens*. Hoary Base Rocket. Linn. Syst. Nat. ed. 12. v. 2. 330. Willd. n. 2. Ait. n. 2? Vahl. Symb. v. 2. 52. (R. hexagyna; Forsk. Ægypt-Arab. 92. Sesamoides salmanticum parvum alterum; Clus. Hist. v. 1. 296, no figure. S. flore albo, foliis canescentibus; Tourn. Inst. 424.)—Leaves lanceolate, waved, somewhat hairy. Branches hispid.—Native of waste ground near Cairo. *Forskall.* Probably also of the south of Europe. The *stems* are decumbent, branched, eighteen inches or more in length, round, leafy, rough with copious, minute, white, spreading, short, bristly hairs. *Leaves* scattered, lanceolate, one and a half or two inches long, bluntish, entire, wavy, and roughish at the edges, as well as at the midrib on both sides; otherwise smooth, and somewhat glaucous; tapering at the base, and sending down two elevated ribs, for some distance, along the branch. *Flowers* in long, terminal, stalked, hairy clusters, on short partial stalks. *Calyx* five-cleft. *Petals* white. *Germen*, according to Forskal's description, stalked, with six *styles*.—Vahl has well remarked that *R. canescens* of Sp. Pl. cannot be the same with the above. Indeed it appears to be no other than either *R. sesamoides* or *purpurascens*, the figure of Clusius agreeing best with the former; his description and the Linnæan definition with the latter. Yet this same figure, adopted by Gerarde, seems to be the only foundation on which *R. canescens* depends for a place in Hort. Kew.—We have never seen the true *canescens* living, nor can we find a figure of it.

3. R. *glauca*. Glaucous Base Rocket. Linn. Sp. Pl. 644. Willd. n. 3. Ait. n. 3. (R. linariæ foliis; Bauh. Prodr. 42, no figure. Sesamoides linariæ folio glauco, pyrenaica, flore stamineo; Moris. sect. 15. t. 1. f. 4.—Leaves linear; toothed at the base. Styles four.—Native of the Pyrenæan mountains; according to Burser's herbarium, examined by Linnæus. Gathered also by Lœfling, in Spain. The *root* is said to be perennial, but has the appearance of being annual. Whole herb glaucous, slender, and smooth. *Stem* twelve or eighteen inches high, simple, round, wand-like, leafy. *Leaves* about two inches long, very narrow; all nearly of equal breadth, furnished at the base with a few white bristly teeth. *Cluster* terminal, solitary, very long, of numerous white *flowers*, whose *petals* are less divided than in most other species.

4. R. *dipetala*. Flax-leaved Base Rocket. Ait. n. 4. Willd. n. 4. Vahl. Symb. v. 2. 52. (R. capensis; Burm. Prodr. 13.)—Leaves linear, entire. Styles four. Petals two, undivided.—Native of the Cape of Good Hope, from whence its seeds were sent to Kew, in 1774, by Mr. Masson. The plant is biennial, flowering in August, being preserved in a greenhouse through the winter. Vahl compares its general aspect to *R. Sesamoides*, hereafter described. *Stem* somewhat shrubby, erect, with round branches. *Leaves* about an inch long, rather fleshy, smooth. *Cluster* terminal, lax. Segments of the *calyx* six, minute, bordered with white. *Petals* only two, wedge-shaped, undivided.

5. R. *purpurascens*. Purplish Base Rocket. Linn. Sp. Pl. 644. Willd. n. 5. (Sesamoides salmanticum parvum primum; Clus. Hist. v. 1. 296, excluding the figure. S. foliis crassis, floribus ex herbaceo purpurascentibus; Tourn. Inst. 424.)—Leaves linear, obtuse. Styles five.—Native of Spain. *Lœfling.*—*Stems* several, a span high, simple, leafy. *Leaves* scattered, the length of the nail, linear, obtuse, smooth. *Cluster*, or rather *spike*, long, lax. *Petals* very white, much divided. *Styles* five, sometimes, as Clusius describes them, only four. *Capsule* with as many protuberant, single-seeded, knobs or pouches.

6. R. *Sesamoides*. Spear-leaved Base Rocket. Linn. Sp. Pl. 644. Willd. n. 6. Ait. n. 5. (Sesamoides parvum salmanticum; Clus. Hist. v. 1. 295, the figure only. Ger. Em. 493. Lob. Ic. 353.)—Stem-leaves linear-lanceolate, obtuse, radical ones lanceolate, stalked, much larger. Fruit stellated.—Native of Barbary, and the south of Europe. A hardy annual in Kew garden, flowering in July and August. The *root* is spindle-shaped, very long, tapering, and branched at the extremity. *Stems* numerous, spreading nearly horizontally, from three to twelve inches long, generally simple, smooth, leafy. *Radical-leaves* numerous, lanceolate or somewhat obovate, entire, smooth, an inch long, tapering down into a *footstalk* of about the same length; *stem-leaves* much smaller and narrower, linear, and obtuse. *Clusters* terminal, rather dense. *Petals* white. *Styles* four or five. *Capsule* of the same number of spreading lobes, fringed at the edges, and assuming a star-like figure.—The wooden cut of Clusius so exactly represents this plant, especially the radical *leaves*, that we can take it for no other. Allioni's plate, t. 88. f. 3, does not accord with this, or any other *Reseda* known to us, except having a general resemblance to *canescens*, n. 2, without its roughness, or the undulations of its *leaves*.

7. R. *fruticulosa*. Shrubby Base Rocket. Linn. Sp. Pl. 645. Willd. n. 7. Ait. n. 6. Jacq. Coll. v. 3. 195. Ic. Rar. t. 474.—Leaves pinnate. Stem shrubby in the lower part. Styles three or four. Petals all three-cleft. Calyx in five spreading segments.—Native of Spain, and other parts of the south of Europe. John Symmons, esq. is recorded by Mr. Aiton as having introduced it into England, in 1794. The *root*, and base of the *stem*, are woody and perennial, producing a number of upright, less durable, *branches*, two or three feet high, leafy, subdivided, smooth, round, with elevated ribs. *Leaves* alternate, stalked, pinnate, of five, seven, or many more, lanceolate, entire, decurrent, smooth *leaflets*, seldom regularly opposite; the terminal one much the largest, sometimes, but not always, recurved at the point; the lower ones gradually smallest. *Clusters* terminal, erect, long, and rather lax. *Petals* five, white, uniform, oblong, all cut, not nearly half way down, into three equal segments. *Styles* often four; sometimes but three. *Stamens* eleven. Linnæus thought it an intermediate species between *alba* and *undata*. From the first of these it is very distinct. By an accidental error in Sp. Pl. the present species is there called *suffruticulosa*, which has led to the same inaccuracy in the Prodr. Fl. Græc. n. 1092. The name is correct in Herb. Linn.

8. R. *alba*. White Base Rocket, or Upright Mignonette. Linn. Sp. Pl. 645. Willd. n. 8. Ait. n. 7. Sm. Fl. Græc. Sibth. t. 459, unpublished. (R. maxima; Bauh. Pin. 100. Lob. Ic. 222. Ger. Em. 277.)—Leaves pinnate. Stem erect, branched. Styles three or four. Petals unequally and deeply five-cleft. Calyx in five spreading segments.—Native of Spain and the south of France; as well as of Greece and the island of Zante. It has been cultivated in our gardens ever since the days of Gerarde, being a hardy annual or biennial, ornamented, throughout the summer, with copious dense *spikes*, of elegant white *flowers*, whose *petals* have deeper, more numerous

ous ſegments, than the foregoing. Otherwiſe their parts of fructification do not much differ. The number of *ſtyles*, and of ſegments of the *calyx*, varies in both, according to luxuriance. The *leaflets* of *alba* are more numerous, as well as more equal in ſize, than in *fruticuloſa*, nor is the terminal one larger than the reſt. Sometimes their edges are roughiſh. Dr. Sibthorp obſerved, that the whole herb, and alſo the bruiſed ſeed, were uſed in Zante to dye ſilk yellow.

9. R. *undata*. Wave-leaved Baſe Rocket. Linn. Sp. Pl. 644. Willd. n. 9. Ait. n. 8. (R. decurſiva; Forſk. Ægypt-Arab. cat. 66. R. minor alba, dentatis foliis; Barrel. Ic. t. 588.)—Leaves pinnate, wavy. Styles three to five. Petals unequally cut.—Native of Spain. Cultivated by Miller, at Chelſea, in 1739. A hardy perennial, flowering in ſummer. The *ſtems* are erect, branched, ſtraight and wand-like, one to two feet high. *Leaves* unequally pinnate, very much criſped, or wavy. *Flowers* ſmaller than in either of the laſt, and of a leſs pure white, compoſing very long *cluſters*, or rather *ſpikes*, for each flower is nearly ſeſſile; the lower ones very remote. Some of the *petals* appear, by the dried ſpecimens, to have three, others five, obtuſe ſegments, of which the lateral ones are broadeſt. We have great doubts, whether the ſpecimen from which Linnæus took his remark of the great ſize of the *capſules*, really belongs to this ſpecies.

10. R. *lutea*. Yellow Baſe Rocket, or Wild Mignonette. Linn. Sp. Pl. 645. Willd. n. 10. Ait. n. 9. Fl. Brit. n. 2. Engl. Bot. t. 321. Jacq. Auſtr. t. 353. Bulliard. t. 281. (R. Plinii; Ger. Em. 277.)—All the leaves three-cleft; the lower ones pinnate. Petals ſix, very unequal. Calyx in ſix ſegments.—Native of dry chalky hills in the temperate and ſouthern countries of Europe; abundant in the chalky parts of England, flowering from June to the end of autumn. The *root*, generally annual with us, often ſurvives a mild winter. *Stems* ſpreading, branched, leafy, a foot or more in height. *Leaves* tapering at the baſe; ſome of them with only one pair of lateral leaflets; others with many, which are occaſionally ſubdivided; all the leaflets, or ſegments, are linear, channelled, more or leſs wavy; frequently very much criſped or curled. Such is the variety, mentioned as a ſpecies, by Dillenius, in Raii Syn. 366, as R. *criſpa gallica*, Bocc. Sic. 77. t. 41. f. 3; but we have often ſuſpected, that Boccone's plant might be the *undata*. It is hazardous, however, to depend much on ſuch imperfect materials as he affords. The *flowers* are numerous, ſulphur-coloured, ſlightly, and not agreeably, odorous; their two upper petals with two fan-like lateral lobes, and a ſhort linear one between; two lateral petals very unequally and variouſly three-cleft; two lower ones narrow, and almoſt ſimple.

11. R. *Phyteuma*. Scentleſs Mignonette. Linn. Sp. Pl. 645. Willd. n. 11. Ait. n. 10. Jacq. Auſtr. t. 132. (Reſedæ affinis Phyteuma; Bauh. Prodr. 42. Erucago apula, trifida et quinquefolia; Column. Ecphr. 267. t. 269. f. 2.)—Leaves undivided, or three-lobed. Calyx in ſix, very large, obovate ſegments. Petals four, more or leſs pectinated.—Native of the ſouth of Europe and north of Africa. On the walls of Rome it is very common, and having a general reſemblance, without the fragrance, of our garden mignonette, it has given riſe to a report of that charming flower being deſtitute of ſcent in Italy! Miller cultivated *R. Phyteuma* at Chelſea, where it ſtill ſprings up annually in the garden. The *root* is long and tapering. *Stems* very numerous, a ſpan high, compoſing a large ſpreading tuft. *Leaves* broadiſh, tapering at the baſe; ſome of them ſimply obovate; others with a pair of lateral lobes. *Flowers* cream-coloured, in lax ſimple cluſters. *Calyx* very much enlarged, and reflexed, after flowering. *Petals* four; the lower pair, in particular, elegantly pectinated at one ſide; but all of them are liable to vary, in the number and depth of their ſegments. *Fruit* pendulous, obovate, angular. *Styles* three.

12. R. *mediterranea*. Mediterranean Mignonette. Linn. Mant. 564. Willd. n. 12. Ait. n. 11. Jacq. Coll. v. 1. 147. Ic. Rar. t. 475.—Leaves flat, undivided, or three-lobed. Calyx much ſhorter than the corolla. Petals ſix, very unequal.—Native of Paleſtine, according to Linnæus, who received it from Schreber. Dr. Sibthorp met with it in corn fields in the iſlands of the Archipelago. This is a hardy annual, flowering all ſummer long, agreeing very much in appearance with the laſt, but ſtill more with the following. The *flowers* have no ſcent. Their *petals* are ſix, moſt reſembling thoſe of *R. lutea* in figure, but white, not yellow. The *leaves* are broader, and leſs divided, than in *lutea*, as well as quite flat; they vary however greatly in breadth, but are never undulated. The *calyx* is ſhort, never enlarged like that of *R. Phyteuma*.

13. R. *odorata*. Sweet Mignonette. Linn. Sp. Pl. 646. Willd. n. 13. Ait. n. 12. Mill. Ic. t. 217. Curt. Mag. t. 29.—Leaves flat; undivided, or three-lobed. Calyx equal to the corolla. Segments of the petals all very deep, ſomewhat ſpatulate.—Native of Egypt. Well known throughout the gardens of Europe, as a hardy annual, blooming all the year round, if properly ſheltered, and exhaling from its neat unoſtentatious flowers, a moſt delicious ſcent, reſembling that of the vine-bloſſom, or the fruit of the raſpberry. This odour remains long in wooden boxes, where the flowers are dried. The *petals* are of a pale buff, prettily contraſted with the red anthers, and, as Jacquin obſerves, in deſcribing the laſt, they differ from that in their uniform, long, wedge-ſhaped, or ſpatulate ſegments.

Reseda, in *Gardening*, contains a plant of the flowering ſweet-ſcented kind, of which the ſpecies cultivated is, the ſweet reſeda, or mignonette (R. odorata).

Mr. Curtis obſerves, that the luxury of the pleaſure-garden is greatly heightened by the delightful odour which this plant diffuſes; and as it grows more readily in pots, its fragrance may be conveyed into the houſe: its perfume, though not ſo refreſhing perhaps as that of the ſweet-briar, is not apt to offend the moſt delicate olfactories.

Method of Culture.—This is raiſed from ſeed, which ſhould be ſown on a moderate hot-bed in March, and when the plants are ſtrong enough to tranſplant, be pricked out upon another moderate hot-bed to bring them forward, having a large ſhare of air in warm weather, to prevent their drawing up weak. Or they may be ſown in pots of light mould, and plunged in the hot-bed, which is probably the better practice. In the firſt mode, about the end of May the plants may be planted out, ſome into pots, to place in or near the apartments, and others into warm borders, where they may remain to flower and ſeed. The plants which grow in the full ground, often produce more ſeeds than thoſe which are in pots; but at the time when the ſeed-veſſels begin to ſwell, the plants are frequently apt to be infeſted with green caterpillars, which, if they are not deſtroyed, eat off all the ſeed-veſſels.

And when the ſeeds are ſown on a bed of light earth in April, the plants come up very well; and when not tranſplanted, grow larger than thoſe which are raiſed in the hot-bed; but they do not flower ſo early, and in cold ſeaſons ſcarcely ripen their ſeeds. In a warm dry border, however, the ſeeds often come up ſpontaneouſly, and grow very luxuriantly; but to have the flowers early in ſpring, the ſeeds ſhould be ſown in pots in autumn, being kept in frames through the winter, or on a gentle hot-bed in ſpring. The plants may alſo be preſerved through the winter in a greenhouſe, where they

they continue flowering moſt part of the year, but the ſecond year they are not ſo vigorous as in the firſt.

It is cultivated for the fine fragrant ſmell which it affords, when pots of it are ſet about the houſe.

The ſeed becomes ripe in the beginning of the autumn, when it ſhould be carefully collected in a dry ſeaſon, and put by in a dry place for future uſe, after having been properly cleaned.

RESEISER, Reseisire, in *Law*, a taking of lands into the king's hands, where a general delivery, or ouſter le main, was formerly miſuſed, contrary to order of law.

RESELE, in *Geography*, a town of Sweden, in Angermannland; 55 miles N.N.E. of Hernoſand.

RESEMBLANCE. See Similitude.

RESENIUS, John Paul, in *Biography*, a Daniſh biſhop and writer, was born at Reſen in 1561. He ſtudied at various ſchools, and in 1583 became ſubdirector of that at Viborg. Some time after he travelled into foreign countries, took a degree at Wittemberg, and returned to Denmark in 1591. He was afterwards appointed profeſſor of logic and theology in the univerſity of Copenhagen, and received orders to accompany Chriſtian IV., who propoſed a viſit to England to ſee his relation, king James. In conſequence of another royal mandate, he undertook to tranſlate the whole of the ſcriptures into Daniſh. He completed the New Teſtament firſt, which he publiſhed in two vols. 12mo. in 1605, and the Old Teſtament followed in 1607. This verſion of the bible gave riſe, in 1609, to a controverſy between Reſenius and Ivarus Stubœus, profeſſor of Hebrew at Copenhagen, the reſult of which was, that Stubœus was diſplaced from his office. In 1614 he was involved in another diſpute with Olaf Coccius, the clergyman of Nicolas' church, Copenhagen, which ended in the diſgrace and baniſhment of his opponent. Reſenius was raiſed to the epiſcopal chair. He died in 1638, and bequeathed upwards of 5000 dollars to charitable purpoſes. He was author of many works, chiefly on ſubjects connected with theology. Gen. Biog.

Resenius, Peter, counſellor of ſtate in Denmark, was born at Copenhagen in 1625, and in 1646 he went to Leyden, where he applied himſelf to the ſtudy of juriſprudence and the belles lettres during the ſpace of four years, and then made a tour to France, Spain, and Italy. He took the degree of L.L.D. at Padua, and then returned to Copenhagen, where he married in 1655, and two years after was appointed profeſſor of moral philoſophy. In 1680 he was ennobled, and in 1684 was nominated a counſellor of ſtate. This learned man died in 1688, and bequeathed a large ſum of money, and a very valuable library, to the univerſity of Copenhagen. He was author of a great number of works, the titles of which are enumerated in the General Biography.

RESENTMENT is a leſſer degree of wrath, which is violent and permanent anger, and is excited by ſmaller offences, or by offences committed againſt leſs irritable minds: it is a deep reflective diſpleaſure againſt the conduct of the offender. Indignation is a reſentment againſt a conduct that appears peculiarly unworthy:—ſome atrocious violation of the principles of gratitude, or ſomething which appears peculiarly deſpicable and baſe. Reſentment is chiefly excited by ſome perſonal offence againſt the laws of ſocial intercourſe, of friendſhip, or of gratitude, and may terminate in indifference, and, in weak minds, in malice; but it is uſually appeaſed by conceſſions and acknowledgments.

RESERVATION, Reservatio, in *Law*, an action or clauſe by which ſomething is reſerved, *i. e.* is retained, kept, or ſecured to one's ſelf.

Thus, when a man lets his land, he reſerves a rent to be paid to himſelf for his maintenance, &c.

William the Conqueror, getting all the lands of England, except thoſe belonging to the church and religious houſes, into his hands by right of conqueſt, beſtowed a great part of them among his followers, reſerving ſome retribution of rents and ſervices to him and his heirs; which reſervation is now, as it was before the Conqueſt, called the tenure of the lands.

Sometimes reſervation ſignifies as much as an exception; as, when a man lets a houſe, and reſerves to himſelf one room, that room is excepted out of the demiſe.

Reservation, *Mental*, is a propoſition, which, ſtrictly taken, and according to the natural import of the terms, is falſe; but if qualified with ſomething reſerved or concealed in the mind, becomes true.

Mental reſervations are the great refuge of religious hypocrites, who uſe them to accommodate their conſciences with their intereſts. The Jeſuits are zealous advocates for mental reſervations; yet are they ſtrictly all real lyes, as including an intention to deceive.

RESERVATORY. See Reservoir.

RESERVE, in *Law*, the ſame with *reſervation;* which ſee.

Benefices are ſometimes reſigned with reſerve of a penſion. By the canon law, no perſon may reſerve to himſelf a penſion out of a benefice, unleſs he hath ſerved it ten years.

In the Romiſh church the ordinary prieſts have only a power to abſolve, in reſerve of certain caſes, hence called *reſerved caſes*, as being reſerved to the biſhop.

The court reſerves the cognizance of ſuch an affair to itſelf. The lawyers ſay, that no prince ever granted ſuch a power by his letters or patents, but that he reſerves to himſelf a greater.

Reserve, *body of*, *corps de reſerve*, in *War*. See Body *of Reſerve*.

Reserve *Guard* denotes the ſame as a *picquet* guard, except that the one mounts at troop-beating, and the other at retreat-beating. See Guard.

RESERVED Cases. See Cases.

RESERVOIR, a large pond or pen of water, artificially made, in order to retain and collect it for the uſe of canals, rivers, mills, &c. See Bason and Canal.

The reſervoir in a building is a large baſon, uſually of wood, lined with lead, where water is kept to ſupply the occaſions of the houſe. At Cannons, the late noble ſeat of the duke of Chandois, there was a very large reſervoir at the top of the houſe, to which the water was raiſed by a curious engine, contrived for the purpoſe. This reſervoir was of ſuch capacity, as that, beſides ſupplying all parts of the houſe by means of pipes and cocks, it likewiſe turned a mill.

The reſervoir is ſometimes alſo a large baſon of ſtrong maſonry, clayed or paved at the bottom, where the water is reſerved to feed jets d'eau, or ſpouting fountains.

Such is that large one on the top of Marley, called *tron d'enfer*, *hell mouth*, whoſe ſurface, Daviler tells us, contains fifty acres, and its depth ſuch as to contain a hundred thouſand cubic fathom of water.

Reſervoirs are of great uſe in collecting and preſerving the urine or other liquid matters diſcharged from the ſheds or ſtables where cattle or other animals are kept, for the purpoſe of manure, and ſhould of courſe be formed on all farm-yards. See Farm-*Yard*.

Such a reſervoir is conceived to be eſſential, even where there are no lands proper for being overflowed by the contents of it, particularly where care is taken to ſupply it occaſionally with a bottom of ſome good rich earthy matter, to to be imbued with the rich particles of the more heavy fubftances which are let fall during the ftagnant ftate of the liquid. This matter fhould be carried out in a dry time, when the water has been wholly removed by evaporation, and be fpread out over the grafs lands, particularly thofe under the fcythe, as foon as poffible after the hay has been taken off the ground. The benefit of a refervoir of this nature, whether formed in the intention of flowing the land below it, or of a pond for catching the mud, will commonly be in the proportion of its extent. And the coft of it will have a relation likewife to its dimenfions. It is fuppofed, that if the expence of one be ten pounds, and the annual increafe of hay only one load, the farmer may well afford to pay fix *per cent.* for the ufe of it. Therefore fuch refervoirs feldom fail to pay amply for the coft of preparing them. In fome floping fituations they may be conftructed at a very trifling expence, in comparifon of their ufefulnefs, when intended to be thrown over grafs lands, with a valve, by which, when full, the liquid may be let off, in a fufficient body, to fpread equally over the whole of the part to which it is applied, and produce the full effect that is wanted.

RESERVOIR, in *Anatomy*. See RECEPTACULUM *Chyli*.

RESET, in *Law*, the receiving or harbouring an outlawed perfon. Hence a receiver of an outlawed perfon is called a *refetter*.

RESHD, or RESHT, in *Geography*, a town of Perfia, and capital of the province of Ghilan, built on the fhore of the Cafpian, and carrying on a confiderable trade in filk, and other articles, with Aftrachan. The number of houfes, which lie difperfed, is eftimated at 2000. The heat in fummer is hardly fupportable, and dangerous, when a particular wind blows, but happily it does not continue above a quarter of an hour. The harbour is unfafe in ftormy weather, fo that the commanders of fhips generally prefer that of Lankeroon, a fmall port in the diftrict of Talifh, to the N.W. of Refht. Rice and wheat are cultivated in its vicinity; 300 miles N. of Ifpahan. N. lat. 37° 20′. E. long. 49° 50′. The province of Ghilan yields a net revenue of 149,490 tomauns, and 9058 dinars.

RESIANCE, RESIANTIA, in *Law*, a man's abode, or continuance in a place.

The word has the fame fignification with regard to laymen, as *refidence* with regard to ecclefiaftics.

Glanville obferves, that in the ancient law, refiance properly fignified a difeafe, by which the perfon was difabled from ftirring out of doors. Whence their *effoin de refiantia*, was the fame as our *effoin de malo lecto*.

RESIANT ROLLS, are rolls in which the refiants of a tithing, &c. are fet down.

RESIDENCE, RESIDENTIA, in *Canon* and *Common Law*, the abode of a perfon, or incumbent, upon his benefice; and his affiduity in attending on the fame.

By the rule of the ancient canon law, beneficiaries are obliged to refidence, without juft and neceffary caufe, and efpecially without the confent of the diocefan, under pain of deprivation of their benefices. The original reafon is, that in the primitive church none were promoted to holy orders, but fuch as had a benefice in promptu, which they were obliged to ferve; fo that this fervice was neceffarily attached to the orders; and whoever was honoured with them, at the fame time was obliged to perfonal fervice.

Regularly, perfonal refidence is required of ecclefiaftical perfons upon their cures; and to that end, by the canon law, if he that hath a benefice with cure be chofen to an office of bailiff, or beadle, or the like fecular office, he may have the king's writ for his difcharge. The intendment of the common law is that a clerk is refident upon his cure. 2 Inft. 625.

Refidence is alfo required by ftatute 9 Ed. II. ftat. 1. c. 8, called the ftatute articuli cleri. Thus alfo, by 21 Henry VIII. c. 13, commonly called the ftatute of non-refidence, perfons wilfully abfenting themfelves from their benefices for one month together, or two months in the year, incur a penalty of 5*l.* to the king, and 5*l.* to any perfon that will fue for the fame. And if any perfon or perfons fhall procure at the court of Rome, or elfewhere, any licence or difpenfation to be non-refident at their faid dignities, prebends, or benefices, contrary to this act; every fuch perfon, putting in execution any fuch difpenfation or licence for himfelf, fhall incur the penalty of 20*l.* for every time fo doing, to be forfeited and recovered as aforefaid, and fuch licence or difpenfation fhall be void. f. 27.

Provided, that this act of non-refidence fhall not extend nor be prejudicial to any fuch fpiritual perfon as fhall chance to be in the king's fervice beyond the fea, nor to any perfon going to any pilgrimage or holy place beyond the fea, during the time that they fhall fo be in the king's fervice, or in the pilgrimage going and returning home; nor to any fcholar or fcholars being converfant and abiding for ftudy, without fraud or covin, at any univerfity within this realm or without; nor to any of the chaplains of the king or queen, daily or quarterly attending and abiding in the king's or queen's moft honourable houfehold; nor to any of the chaplains of the prince or princefs, or any of the king's or queen's children, brethren, or fifters, attending daily in their honourable houfeholds, during fo long as they fhall attend in any of their houfeholds; nor to any chaplain of any archbifhop or bifhop, or of any fpiritual or temporal lords of the parliament, daily attending, abiding, and remaining in any of their honourable houfeholds; nor to any chaplain of any duchefs, marquefs, countefs, vifcountefs, or baronefs, attending daily, and abiding in any of their honourable houfeholds; nor to any chaplain of the lord chancellor, or treafurer of England, the king's chamberlain, or fteward of his houfehold for the time being, the treafurer and controller of the king's moft honourable houfehold for the time being, attending daily in any of their honourable houfeholds; nor to any chaplain of any of the knights of the honourable order of the garter, or of the chief juftice of the king's bench, warden of the ports, or of the mafter of the rolls, nor to any chaplain of the king's fecretary, dean of the chapel, amner for the time being, daily attending and dwelling in any of their houfeholds, during the time that they fhall fo abide and dwell, without fraud or covin, in any of the faid honourable houfeholds; nor to the mafter of the rolls, or dean of the arches, nor to any chancellor or commiffary of any archbifhop or bifhop, nor to as many of the twelve mafters of the chancery, and twelve advocates of the arches, as fhall be fpiritual men, during fo long time as they fhall occupy their faid rooms and offices; nor to any fuch fpiritual perfons as fhall happen by injunction of the lord chancellor, or the king's council, to be bound to any daily appearance and attendance to anfwer to the law, during the time of fuch injunction. f. 28.

Provided alfo, that it fhall be lawful to the king to give licence to every of his own chaplains, for non-refidence upon their benefices; any thing in this act to the contrary notwithftanding. f. 29.

Provided alfo, that every duchefs, marquefs, countefs, baronefs, widows, which fhall take any hufbands under the degree of a baron, may take fuch number of chaplains as they might have done being widows; and that every fuch chaplain may have like liberty of non-refidence, as they might have had if their faid ladies and miftreffes had kept themfelves widows. f. 33.

Legal refidence is not only in the parifh, but alfo in the parfonage parsonage house; for it hath been resolved, that the statute intended residence, not only for serving the cure, and for hospitality, but also for maintaining the house, that the successor also may keep hospitality there. 25 Hen. VIII. cap. 16. 33 Hen. VIII. cap. 28. 28 Hen. VIII. cap. 13.

On a review of these statutes, a question has occurred, how far, taken together, they supersede the canon law, so as to take away the power which the ordinary had before, of enjoining residence to the clergy of his diocese. It seems to be clear, that before these statutes, the bishops of this realm had and exercised a power of calling their clergy to residence; but more frequently, they did not exert this power, which so far forth was to the clergy a virtual dispensation for non-residence. But this not exerting of their power was in them not always voluntary; for they were under the controlling influence of the pope, who granted dispensations of non-residence to as many as would purchase them, and disposed of abundance of ecclesiastical preferments to foreigners, who never resided here at all. The king also, as appears, had a power to require the service of clergymen; and consequently in such case to dispense with them for non residence upon their benefices. This power of the king is reserved to him by the aforesaid act of the 21 Hen. VIII. c. 13. But it is the power of dispensation in the two former cases which is intended to be taken away, namely, by the bishop, and by the pope; and by the said act residence is injoined to the clergy, under the penalty therein mentioned, notwithstanding any dispensation to the contrary, from the court of Rome or elsewhere; with a proviso nevertheless, that the said act shall not extend nor be prejudicial to the chaplains and others therein specially excepted. It is argued, that this act being made to rectify what had been insufficient or ineffectual in the canon law, and inflicting a temporal penalty to inforce the obligation of residence, the parliament intended that the said act should be, from thenceforth, if not the sole, yet the principal rule of proceeding in this particular; and consequently, that the persons excepted in the act need no other exemption than what is given to them by the act of their non-residence. Unto this it is answered, that the intention of the act was not to take away any power which the bishop had of injoining residence, but the contrary; namely, it was to take away that power which the bishop or pope exercised, of granting dispensations for non-residence, that is to say, the act left to them that power which was beneficial, and only took from them that which tended to the detriment of the church; and, consequently, that the bishop may injoin residence to the clergy as he might before, only he may not dispense with them as he did before for non-residence. And indeed, from any thing that appears upon the face of the act, the contrary supposition seemeth to bear somewhat hard against the rule which hath generally been adhered to in the construction of acts of parliament, that an act of parliament in the affirmative doth not take away the ecclesiastical jurisdiction, and that the same shall not be taken away in any act of parliament, but by express words. It is therefore further urged, that the three subsequent acts do explain this act, and by the express words thereof do establish the foregoing interpretation. In the first of the three it is said, that the persons therein mentioned may retain one chaplain *which may be absent from his benefice, and not resident upon the same;* in the second it is said, that persons above forty years of age, residing in the universities, *shall not be excused of their non-residence,* and again, that persons *under* forty years of age, *shall not enjoy the privilege of non-residence contained in the proviso of the said former act,* unless they perform the common exercises there, and the like, which implies, that if they do this, they shall enjoy such privilege: and in the third, it is said, that the persons therein mentioned may retain one chaplain, *which may be absent from his benefice, and non-resident upon the same;* and it is not to be supposed, that the parliament intended a greater privilege to the chaplains of the inferior officers mentioned in the said last act, than to the chaplains of the royal family and principal nobility mentioned in the first act. Unto this the most apposite answer seemeth to be, that it is not expressed absolutely in any of the said three acts, that the chaplains or others therein mentioned shall enjoy the privilege of non-residence, or may be absent from their benefices, and not resident upon the same; but only this, that they may be absent or non-resident as aforesaid, *the said statute made in the said twenty-first year, or any other statute or ordinance to the contrary notwithstanding.* So that they are only exempted thereby from the restraints introduced by the statute law; but in other respects are left as they were before.—But concerning this, although it is a case likely enough to happen every day, there hath been no adjudication.

By 43 Geo. III. c. 84. it is enacted, that so much of 21 Hen. VIII. c. 13. as imposes the penalty of ten pounds on any spiritual person who shall not keep residence on one of his dignities, prebends, or benefices, but absent himself one month together, or two months, to be accounted at several times, in any one year, shall be, and the same is hereby repealed; and that every spiritual person, being possessed of any archdeaconry, deanery, or other dignity, prebend, benefice, donative, or perpetual curacy, or parochial chapelry, who shall, without sufficient cause, as in the said act, or the 25 Hen VIII. c. 16. or in 28 Hen. VIII. c. 13. or in 33 Hen. VIII. c. 28. is specified, or such other sufficient cause as would exempt such spiritual person from any of the pains, penalties, and forfeitures under the said recited acts, for any non-residence, and who shall not have any such licence or exemption as is in this act mentioned, wilfully absent himself therefrom for three months together, or to be accounted at several times in any one year, and make his residence at any other place or places, except at some other dignity, prebend, benefice, donative, perpetual curacy, or parochial chapelry, of which he may be possessed, shall, when such absence shall exceed such period, and not exceed six months, forfeit and pay one-third of the annual value of the dignity, prebend, benefice, donative, perpetual curacy, or parochial chapelry, from which he shall so absent himself; and when such absence shall exceed six months, and not eight months, one-half of such annual value; and when such absence shall exceed eight months, two-thirds of such annual value; and when such absence shall have been for the whole of the year, three-fourths of such annual value; to be recovered by action of debt, bill, plaint, or information, in any of his majesty's courts of record at Westminster, or the courts of great sessions in Wales, wherein no essoign, privilege, protection, or wager of law, or more than one imparlance, shall be allowed; and the whole of every such penalty or forfeiture shall go and be paid to the person or persons who shall inform and sue for the same, together with such costs of suit as shall be allowed; provided that no parsonage that hath a vicar endowed, or perpetual curate, and having no cure of souls, shall be taken to be or be comprehended under the name of benefice, within the meaning of this act. s. 12.

No spiritual person holding any office, in such manner as the same, under any of the provisions of the said recited acts, would exempt such spiritual persons from residence, or from the penalties and forfeitures in the said acts contained for non-residence, or actually serving as a chaplain of the house of commons, or as a clerk of his majesty's closet, or as a deputy clerk thereof, or as a chaplain general of his majesty's forces, or brigade chaplain on foreign service, or chaplain on board any of his majesty's ships, or of his majesty's dock yards, or in any of his majesty's garrisons, or chaplain of his majesty's corps of artillery, or as chaplain to any British factory, or in the household of any British ambassador or public minister residing abroad, or as chancellor or vicar-general, or in his absence the principal surrogate or official in any ecclesiastical court of any diocese, or as minor canon, or vicar-choral, or priest, vicar, or any such other public officer in any cathedral or collegiate church, or as deans, sub-deans, priests, or readers in his majesty's royal chapels at St. James's and Whitehall, or as reader in his majesty's private chapel at Windsor, or elsewhere, or as chaplain at the royal military asylum at Chelsea, or royal military college at High Wycombe, or teacher at the royal military academy at Woolwich, or chaplains at the royal hospitals at Greenwich and Chelsea, or as chaplains to the royal hospitals for seamen at Haslar and Plymouth, or as a preacher or reader in any of the inns of court, or at the rolls, or as bursar, dean, vice-president or public tutor or chaplain, or other such public officer, in any college or hall, in either of the universities of Oxford or Cambridge, or as public librarian or public registrar, or proctor, or public orator, or other such public officer, in either of the said universities, or as fellow of any college in either of the universities, or of Eton or Winchester college, or as warden or provost of Eton or Winchester college, or as schoolmaster or usher in the same, or as schoolmaster or usher of Westminster-school, during the period that they shall respectively be required, by reason of any such office, to perform the duties of the same, and actually shall perform the duties of the same, shall be liable to any of the pains, penalties, or forfeitures in the said first recited act or this act contained, for or on account of any non-residence on any dignity, prebend, benefice, donative, or perpetual curacy. s. 15.

It shall be lawful for any bishop to grant licences to spiritual persons within his diocese, to reside out of the proper house of residence, or out of the parish, and within such distance therefrom, as the case may appear to such bishop to require, if such bishop shall, in his discretion, think the same fit and proper, in the several cases hereinafter mentioned; (that is to say,) to any spiritual person who shall be prevented from residing in the proper house of residence, or in the parish, by actual illness of himself, or wife or child; and also to any spiritual person having any dignity, prebend, benefice, donative, perpetual curacy, or parochial chapelry, where there shall be no house of residence, or where the house of residence shall be unfit for the residence of such ecclesiastical person, such unfitness not being occasioned by such ecclesiastical person, such spiritual person keeping such house in such repair as shall be to the satisfaction of the bishop; and also to any spiritual person having any benefice, donative, perpetual curacy, or parochial chapelry, and having any mansion or messuage belonging to himself or any relative, to reside in such mansion or messuage, such spiritual person keeping the house of residence in good repair, to the satisfaction of the bishop; and also to any spiritual person having any benefice, donative, perpetual curacy, or parochial chapelry, of small value, and serving as a stipendiary curate elsewhere, with licence, and providing for the serving of such his benefice, donative, perpetual curacy, or parochial chapelry, to the satisfaction of the bishop of his diocese; and also to any master or usher of any endowed school duly licensed by the bishop, and actually employed in teaching therein, or to the master of any other school who now is or shall be, within one month after the passing of this act, duly licensed by the bishop; and also to any master or preacher of hospitals or incorporated charitable foundation, during the period for which he may be required to reside in the same, and shall actually reside and perform his duties therein; or to any person holding any endowed lectureship, chapelry, or preachership, and performing the duties thereof respectively; or to any spiritual person having any benefice, donative, perpetual curacy, or parochial chapelry of small value, and serving as preacher in any proprietary chapel in cities or towns, with the licence of the bishop in whose diocese he shall so officiate; or to the librarians of the British museum, or of Sion college; or to the trustees of lord Crewe's charity, during the times of their personal attendance on the duties of their office: provided always, that for any such licence, the party obtaining the same shall not pay more than the sum of ten shillings, exclusive of any such stamps as may be required by law: provided always, that if any spiritual person, applying to any bishop for any such licence, shall think himself aggrieved by the refusal thereof, it shall be lawful for such spiritual person to appeal to the archbishop of the province, who shall confirm such refusal, or grant a licence under this act, as shall seem just and proper. s. 19.

It shall be lawful for any bishop, in cases not enumerated, to grant licences to reside out of the proper house of residence, or out of the parish, and to assign to a curate such salary as he shall judge fit: provided, that in every such case, the reasons that have induced such bishop to grant such licence shall be transmitted to the archbishop of the province to which such bishop shall belong, who shall allow or disallow such licence, in the whole, or in part, or make any alteration therein, as to the period for which the same may have been granted, or otherwise, and likewise as to the stipend assigned to the curate, as to such archbishop shall seem fit; and no such licence shall be good unless it shall have been so allowed and approved by such archbishop: provided also, that no licence shall be made void by the death or removal of the bishop or archbishop granting the same, but the same shall be good and valid, unless the same shall be revoked by the next or any succeeding bishop or archbishop: provided also, that any spiritual person may appeal against any such revocation by the bishop alone: provided also, that the respective archbishops may, in their respective dioceses of which they are bishops, grant licences in all cases in which any licences may be granted by any bishop, either by his own authority, or with the allowance and approval of the archbishop as aforesaid: provided also, that it shall be lawful for any such archbishop to order reasonable fees and charges to be paid by any such spiritual person appealing: provided always, that in every case when any costs and charges directed by such archbishop or bishop as aforesaid, shall remain unpaid for the period of twenty-one days after demand thereof, it shall be lawful for such bishop or archbishop to cause the same to be recovered by sequestration. s. 21.

Provided always, that it shall be lawful for any bishop or archbishop to revoke any such licence: provided also, that no licence for non-residence granted under this act shall continue in force for more than two years from the granting thereof.

Every bishop or archbishop shall cause a copy of such licence or revocation to be filed in the registry of the diocese; and a list shall be made out by the register of the said diocese, and entered in a book, and kept for the inspection of all persons; and a copy of every such licence and revocation shall be transmitted to the churchwardens of the parish to which the same relates, within one month after the grant thereof.

thereof, to be by them depofited in the parifh cheft; and a copy of the fame fhall likewife be read at the vifitation of the archdeacon. f. 22.

Provided, that during the vacancy of any fee, the power of granting licences under this act fhall be exercifed by the vicar-general of the diocefe; and that during the abfence of any prelate out of the realm, or fuch infirmity as difables him from exercifing in perfon the functions of his office, it fhall be exercifed by fuch perfon or perfons as is or are lawfully empowered to exercife his general jurifdiction in the diocefe. f. 28.

And nothing in this act fhall exempt any perfon or perfons from any canonical or ecclefiaftical cenfures, or affect any proceedings in any ecclefiaftical court, in relation to non-refidence, not being duly licenfed according to the provifions of this act, to be abfent therefrom, nor having any other lawful caufe of abfence; provided no fuch cenfures, by reafon of any non-refidence, not exceeding three months in any one year, fhall be put in force at the fuit or inftance of any perfon or perfons other than the archbifhop, bifhop, or archdeacon. f. 29.

In every cafe in which it fhall appear to any bifhop or archbifhop, that any fpiritual perfon, not being licenfed according to this act, nor having any other lawful caufe of abfence, does not fufficiently refide, it fhall be lawful for fuch bifhop or archbifhop to iffue a monition to fuch fpiritual perfon, to refide thereon, and to make a return to fuch monition within a certain number of days after the iffuing thereof; fo as that there fhall be thirty days between the time of executing fuch monition, and the time fpecified for the return thereto; and it fhall be lawful for the bifhop or archbifhop to whom any fuch return fhall be made, to require fuch return to be verified by the oath of fuch fpiritual perfon, or others; and where no fuch return fhall be made, or where fuch return fhall not be deemed fatisfactory, it fhall be lawful for fuch bifhop or archbifhop to iffue an order to require fuch perfon to proceed to and refide, within thirty days after fuch order fhall have been delivered; and in cafe of non-compliance, to fequefter the profits of fuch benefice, donative, perpetual curacy, or parochial chapelry of fuch fpiritual perfon, and to direct the application of fuch profits, after deducting the neceffary expences of ferving the cure, to the payment of fuch expences as fhall have been incurred in relation to fuch monition and fequeftration, and in the next place, towards the augmentation or improvement of any fuch parfonage, vicarage, donative, or perpetual curacy, or the houfe of refidence, or any of the buildings and appurtenances, or any of the glebe or demefne lands; or may order and direct the fame, or any portion thereof, to be paid to the governors of the bounty of queen Anne, to be applied as fuch bifhop or archbifhop fhall in his difcretion think fit; and it fhall alfo be lawful for any fuch bifhop or archbifhop, within fix months after fuch order for fequeftration, or within fix months after any money fhall have been actually levied by fuch fequeftration, to remit to any fuch fpiritual perfon any part of fuch profits, or caufe the fame or any part thereof that fhall have been paid to fuch governors of queen Anne's bounty, to be repaid to fuch fpiritual perfon, in any cafe in which, by reafon of the fubfequent obedience of any fuch fpiritual perfon, fuch bifhop or archbifhop fhall think the fame proper: provided, that when any fuch fpiritual perfon fhall think himfelf aggrieved by reafon of any fuch fequeftration, it fhall be lawful for any fuch fpiritual perfon to appeal to the archbifhop, who fhall make fuch order as fhall be juft and proper: provided, that the party fo appealing fhall give fecurity to the bifhop for the payment of expences occafioned by the appeal: provided alfo, that no fuch order for any fequeftration fhall be put in force during fuch appeal. f. 30.

Perfons who fhall return to refidence on monition, fhall pay the cofts. f. 31.

If any perfon, returning to refidence on monition, fhall before fix months thereafter abfent himfelf, the bifhop may, without monition, fequeftrate the profits of the benefice. f. 32.

And if any clerk fhall continue under any fequeftration for non-refidence for the fpace of three years, or fhall incur three fequeftrations in the faid fpace of three years, not being relieved with refpect to any of fuch fequeftrations, upon appeal, the benefice fhall become *ipfo facto* void, and the patron or perfon entitled to prefent or nominate fome clerk thereto, other than the clerk who fhall have fo continued under fuch fequeftration or fequeftrations. f. 33.

Provided, that if an action be brought before the iffuing of the monition, the bifhop or archbifhop fhall retain out of the profits of the benefice fufficient to fatisfy the penalty and cofts; but if at the time of filing the monition, no action fhall have been commenced, none fhall be brought afterwards. f. 36.

But nothing in this act contained fhall affect his majefty's royal prerogative in the granting of difpenfations for non-refidence, nor any privilege of clerks retained in his majefty's fervice under the ftatute 9 Edward II. c. 8.—f. 40.

No archbifhop or bifhop having any dignity, prebend, benefice, donative, or perpetual cure, fhall, by reafon of non-refidence, be fubject or liable to any penalties or forfeitures. f. 41.

By 54 Geo. III. c. 175. bifhops are empowered to punifh paft non-refidence by monition and fequeftration, as well as to compel refidence in future, and to exercife the fame powers of remitting or ordering the repayment of any part of fuch penalties as is directed or allowed in 43 Geo. III. c. 84. Perfons may appeal, as under the laft cited act, and penalties may be remitted; nor are penalties recoverable for more than one year. This ftatute repeals the provifion of the former act 43 Geo. III. as to perfons neglecting to notify the caufe of exemption from refidence, for which it is not neceffary to obtain a licence, and enacts that a perfon chargeable with fuch neglect fhall forfeit and pay for fuch offence the fum of 20*l.* to be levied by fequeftration, if not otherwife paid after monition, to be applied as the archbifhop or bifhop of the diocefe to whom the notification ought to have been made fhall direct, who poffeffes the power of remitting or ordering the repayment of any part of fuch penalties, as is allowed in the faid act, in cafes of non-compliance with an order for refidence. A perfon who has no houfe of refidence, but who fhall have refided nine months in the year within the limits of his benefice, donative, perpetual curacy, or parochial chapelry, fhall not be liable to any penalties on account of non-refidence, nor be obliged to take out any licence for it; but the fame fhall be deemed a legal refidence; and in all returns made by the bifhops, perfons fo refiding fhall be returned as refident. It is enacted alfo, that houfes purchafed by the governors of queen Anne's bounty, though not fituated within the parifhes for which they are purchafed, fhall be deemed refidences; and in all cafes of finecure rectories having vicarages endowed, the refidence of the vicar in the rectory houfe fhall be deemed a fufficient legal refidence.

For leafes of non-refidents, fee LEASE.

We

We obferve here, that the act of 13 Eliz. c. 20, referred to under LEASE, which was at firft temporary, but made perpetual by 3 Car I. c. 4, is repealed by 43 Geo. III. c. 84, as well as feveral other ftatutes, fo far as they relate to it. This ftatute enacts, that fpiritual perfons may take houfes, &c. though not in a city, &c. and fuch as have not fufficient glebe may, by confent of the bifhop, take farms. They may alfo hold eftates as property, but not any farm for cultivation, unlefs under a leafe granted on or before Jan. 1, 1803, or by confent of the bifhop. They may alfo buy or fell cattle or corn for the occupation of farms. Vicars or curates may take leafes of the impropriate parfonages of their parifhes; but if not occupied by a fpiritual perfon before the paffing of this act, the licence of the bifhop is neceffary. A licenfed clergyman, or one exempt from refidence, may occupy, where he refides, fuch lands as the bifhop may allow. This ftatute is amended, in feveral refpects, by 54 Geo. III. c. 175. By one claufe in this laft act, fo much of 53 Geo. III. c. 149, as enacts that incumbents, neglecting to notify the death of a curate, fhall lofe his exemption from refidence, or licence for non-refidence, is repealed; and a penalty of 20*l.* is impofed.

By 53 Geo. III. c. 149. f. 2, the bifhop or ordinary is empowered to appoint falaries to licenfed curates; the licence fpecifying the amount of fuch falary; and curates may be directed to refide in the parfonage houfe in cafe of the non-refidence of incumbents for four months in each year, during the faid non-refidence: but the diftance of the refidence of fuch curate, licenfed to refide out of the parifh, from any church or chapel which he fhall be licenfed to ferve, fhall not exceed five ftatute miles, except in cafes of neceffity, to be approved by the bifhop or ordinary, and fpecified in the licence. The bifhop may direct the curate to give up poffeffion of the parfonage or vicarage houfe, and in cafe of refufal, he fhall forfeit to the rector or vicar, all fuch parts of his ftipend as fhall then be unpaid, or fhall thereafter become due, and alfo the fum of 50*l.* to fuch rector or vicar, recoverable in an action of debt. The falaries payable to curates fhall be in proportion to the value of the benefices; in no cafe lefs than 80*l. per annum,* or than the annual value of the benefice, donative, perpetual curacy, or parochial chapelry, if the faid value fhall not amount to 80*l. per annum;* nor lefs than 100*l. per annum,* or the whole value as aforefaid, if the faid value fhall not amount to 100*l. per annum* in any parifh or place where the population, (according to the returns then laft made in purfuance of any act or acts of parliament,) fhall amount to or exceed 300 perfons; and fuch falary fhall not be lefs than 120*l. per annum,* or the whole value as aforefaid, if the faid value fhall not amount to 120*l. per annum,* in any parifh or place where the population fhall appear as aforefaid to amount to or exceed 500 perfons; and fuch falary fhall not be lefs than 150*l. per annum,* or than the whole value as aforefaid, if the faid value fhall not amount to 150*l. per annum,* in any parifh or place where the population fhall appear, as aforefaid, to amount to or exceed 1000 perfons: provided always, that the annual value of all benefices, donatives, perpetual curacies, or parochial chapelries, of which the faid value, eftimated as is herein provided, does not amount to 150*l. per annum,* fhall be eftimated from the returns made by the bifhops of the feveral diocefes to the governors of queen Anne's bounty, in purfuance of an addrefs of the houfe of lords, or from any future returns which may be made by the faid bifhops to the faid governors, refpecting parifhes or places omitted in the faid returns, or refpecting parifhes or places in the actual income of which it fhall be made appear to the faid bifhops that any confiderable variation has taken place, either by augmentations made by the faid governors or otherwife.

However, where the curate's falary is of the value of the benefice, it fhall be liable to the charges affecting it. When the curate is permitted to ferve in an adjoining parifh, it fhall be lawful for the bifhop or ordinary to appoint for fuch incumbent, or perpetual curate, fo licenfed, a falary lefs by a fum not exceeding 30*l. per annum,* than the falary which in the feveral cafes herein before mentioned the bifhop or ordinary is refpectively required by this act to appoint; and in every cafe where the bifhop or ordinary fhall find it neceffary or expedient as aforefaid, to licenfe one and the fame perfon to ferve as curate for two adjoining or other parifhes or places, it fhall be lawful for fuch bifhop or ordinary to direct that during fuch time as fuch curate fhall ferve fuch two churches or chapels, the falary to be received by him for ferving each of the faid churches or chapels fhall be lefs by a fum not exceeding 30*l. per annum,* than the falary which in the feveral cafes herein before mentioned the bifhop or ordinary is required by this act to appoint: Provided always, that no fuch falary fhall in any cafe be lefs than 50*l. per annum,* or than the whole value of the faid benefice, donative, perpetual curacy, or parochial chapelry, which fuch incumbent, perpetual curate, or curate, fhall be licenfed to ferve, if the faid value fhall not amount to 50*l. per annum:* Provided always, that no incumbent, perpetual curate, or curate, fhall be licenfed to ferve as curate in any church or chapel which is diftant more than five ftatute miles from any church or chapel already ferved by fuch incumbent, perpetual curate, or curate, except in cafes of neceffity, to be approved by the bifhop or ordinary, and fpecified in the licence.

In certain cafes, fmaller falaries are to be allowed to curates. The bifhop is to allow the rector, &c. to deduct from the curate's falary for repairs to a limited amount, fo that it fhall not in any year exceed one-fourth part of the falary allotted to the curate. The curate is required, in certain cafes, to pay the taxes of the parfonage houfe. Where the benefice, clear of all deductions, exceeds 400*l. per annum,* the bifhop may affign to the curate of fuch parifh or place, refident within the fame, and ferving no other cure, a falary of 100*l. per annum,* though the population may not amount to 300 perfons; and if the population fhould amount to 500 perfons, the bifhop may affign to the curate any larger ftipend or allowance, fo that the fame fhall not exceed by more than 50*l. per annum* the amount of the ftipend or allowance before fpecified, as required to be affigned to fuch curate. No licence fhall be granted to ferve more than two churches in one day; excepting only in certain cafes, where three chapels or churches are not diftant from each other more than four meafured miles, the reafons for granting fuch licence being ftated in it; and it is required that the refidence of the curate be fuch, that it fhall not be neceffary for him to travel more than fifteen miles to perform his whole duty. An incumbent applying for licence for non-refidence fhall ftate what falary he propofes to give to his curate. See CURATE.

Bifhops are not punifhable by the ftatute of the 21 Hen. VIII. for non-refidence upon their bifhoprics; but although an archbifhop or bifhop be not tied to be refident upon his bifhopric by the ftatutes; yet they are thereto obliged by the ecclefiaftical law, and may be compelled to keep refidence by ecclefiaftical cenfures. (Watf. c. 37.) See alfo the conftitutions of archbifhop Langton, of Otho, and of Othobon. By canon 42, every dean, mafter, or warden, or chief governor of any cathedral or collegiate church, fhall be refident in the fame fourfcore and ten days, *conjunctim* or *divifim,* *divisim*, in every year at the leaſt, and then ſhall continue there in preaching the word of God, and keeping good hoſpitality; except he ſhall be otherwiſe let with weighty and urgent cauſes, to be approved by the biſhop of the dioceſe, or in any other lawful ſort diſpenſed with.

By can. 44 no prebendaries nor canons in cathedral or collegiate churches, having one or more benefices with cure, (and not being reſidentiaries in the ſame cathedral or collegiate churches,) ſhall, under colour of their ſaid prebends, abſent themſelves from their benefices with cure above the ſpace of one month in the year, unleſs it be for ſome urgent cauſe, and certain time to be allowed by the biſhop of the dioceſe. And ſuch of the ſaid canons and prebendaries, as by the ordinances of the cathedral or collegiate churches do ſtand bound to be reſident in the ſame, ſhall ſo among themſelves ſort and proportion the times of the year, concerning reſidence to be kept in the ſaid churches, as that ſome of them always ſhall be perſonally reſident there; and all thoſe who be, or ſhall be reſidentiaries in any cathedral or collegiate church, ſhall, after the days of their reſidency appointed by their local ſtatutes or cuſtom expired, preſently repair to their benefices, or ſome one of them, or to ſome other charge where the law requireth their preſence, there to diſcharge their duties according to the laws in that caſe provided. And the biſhop of the dioceſe ſhall ſee the ſame to be duly performed and put in execution.

So that, beſides the general laws directing the reſidence of other clergymen, theſe dignitaries have another law peculiar to themſelves, namely, the local ſtatutes of their reſpective foundations, the validity of which local ſtatutes this canon ſuppoſeth and affirmeth. And, with reſpect to the new foundations in particular, the act of parliament of the 6 Anne, c. 21. enacteth that their local ſtatutes ſhall be in force, ſo far as they are not contrary to the conſtitution of the church of England, or the laws of the land. This canon is undoubtedly a part of the conſtitution of the church: ſo that if the canon interfereth in any reſpect with the ſaid local ſtatutes, the canon is to be preferred, and the local ſtatutes to be in force only ſo far forth as they are modified and regulated by the canon.

There doth not appear to be any difference, either by the eccleſiaſtical or temporal laws of this kingdom, between the caſe of a rector and of a vicar concerning reſidence; except only that the vicar is ſworn to reſide, (with a proviſo, unleſs he ſhall be otherwiſe diſpenſed withal by his dioceſan,) and the rector is not ſworn. And the reaſon of this difference was this: in the council of Lateran, held under Alexander III., and in another Lateran council, held under Innocent III., there were very ſtrict canons made againſt pluralities; by the firſt of theſe councils pluralities are reſtrained, and every perſon admitted *ad eccleſiam, vel eccleſiaſticum miniſterium,* is bound to reſide there, and perſonally ſerve the cure; by the ſecond of theſe councils, if any perſon, having one benefice with cure of ſouls, accepts of a ſecond, his firſt is declared void *ipſo jure.* Theſe canons were received in England, and are ſtill part of our eccleſiaſtical law.

At the firſt appearance of theſe canons, there was no doubt made but they obliged all *rectors;* for they, according to the language of the law, had churches *in title,* and had *beneficium eccleſiaſticum:* and of ſuch the canons ſpoke. But *vicars* did not then look upon themſelves to be bound by theſe canons, for they, as the gloſs upon the decretals ſpeaks, had not *eccleſiam quoad titulum*; and the text of the law deſcribes them, not as *having benefices,* but as bound *perſonis et eccleſiis deſervire,* that is, as aſſiſtant to the rector in his church.

Upon this notion a practice was founded, and prevailed in England, which eluded the canons made againſt pluralities. A man beneficed in one church could not accept another, without avoiding the firſt; but a man poſſeſſed of a benefice, could accept a vicarage under the rector in another church, for that was no benefice in law, and therefore not within the letter of the canon, which forbids any man holding two benefices.

The way then of taking a ſecond living in fraud of the canon was this: a friend was preſented, who took the inſtitution, and had the church *quoad titulum;* as ſoon as he was poſſeſſed, he conſtituted the perſon vicar for whoſe benefit he took the living, and by conſent of the dioceſan, allotted the whole profit of the living for the vicar's portion, except a ſmall matter reſerved to himſelf.

This vicar went and reſided upon his firſt living, for the canon reached him where he had the *benefice;* but having no benefice where he had only a vicarage, he thought himſelf ſecure againſt the ſaid canons requiring reſidence.

This piece of management gave occaſion to ſeveral papal decrees, and to the following conſtitution of archbiſhop Langton; *viz.* No ordinary ſhall admit any one to a vicarage, who will not perſonally officiate there. Lind. 64.

And to another conſtitution of the ſame archbiſhop, by which it is injoined, that vicars who will be non-reſident ſhall be deprived. Lind. 131.

But the abuſe ſtill continued, and therefore Otho, in his legatine conſtitutions, applied a ſtronger remedy, ordaining, That none ſhall be admitted to a vicarage, but who, renouncing all other benefices (if he hath any) with cure of ſouls, ſhall ſwear that he will make reſidence there, and ſhall conſtantly ſo reſide: otherwiſe his inſtitution ſhall be null, and the vicarage ſhall be given to another. Athon. 24.

And it is upon the authority of this conſtitution that the oath of reſidence is adminiſtered to vicars to this day. And this obligation of vicars to reſidence was further inforced by a conſtitution of Othobon, as followeth: If any ſhall detain a vicarage contrary to the aforeſaid conſtitution of Otho, he ſhall not appropriate to himſelf the profits thereof, but ſhall reſtore the ſame; one moiety whereof ſhall be applied to the uſe of that church, and the other moiety ſhall be diſtributed half to the poor of the pariſh, and half to the archdeacon. And the archdeacon ſhall make diligent inquiry every year, and cauſe this conſtitution to be ſtrictly obſerved. And if he ſhall find that any one detaineth a vicarage contrary to the premiſes, he ſhall forthwith notify to the ordinary that ſuch vicarage is vacant, who ſhall do what to him belongeth in the premiſes; and if the ordinary ſhall delay to inſtitute another into ſuch vicarage, he ſhall be ſuſpended from collation, inſtitution, or preſentation to any benefices until he ſhall comply. And if any one ſhall ſtrive to detain a vicarage contrary to the premiſes, and perſiſt in his obſtinacy for a month; he ſhall, beſides the penalties aforeſaid, be *ipſo facto* deprived of his other benefices (if he have any); and ſhall be diſabled for ever to hold ſuch vicarage, which he hath ſo vexatiouſly detained, and from obtaining any other benefice for three years. And if the archdeacon ſhall be remiſs in the premiſes, he ſhall be deprived of the ſhare of the aforeſaid penalty aſſigned to him, and be ſuſpended from the entrance of the church, until he ſhall perform his duty. Athon. 95.

So that, upon the whole, the doubt was not, whether rectors were obliged to reſidence; the only queſtion was, whether vicars were alſo obliged: and to inforce the reſidence

dence of vicars, in like manner as of rectors, the aforesaid constitutions were ordained. Sherl. ibid. p. 20, 21, 22.

By the 43 Geo. III. c. 84. no oath shall be required of or taken by any vicar in relation to residence on his vicarage. f. 37.

Can. 47. Every beneficed man licensed by the laws of this realm, upon urgent occasions of other service, not to reside upon his benefice, shall cause his cure to be supplied by a curate that is a sufficient and licensed preacher, if the worth of the benefice will bear it. But whosoever hath two benefices, shall maintain a preacher licensed in the benefice where he doth not reside, except he preach himself at both of them usually.

And by the last article of archbishop Wake's directions it is required, that the bishop shall take care, as much as possible, that whosoever is admitted to serve any cure, do reside in the parish where he is to serve; especially in livings that are able to support a resident cure: and where that cannot be done, that they do at at least reside so near to the place, that they may conveniently perform all their duties, both in the church and parish.

By the 36 Geo. III. c. 83. the ordinary, besides appointing to curates an allowance not exceeding 75*l. per ann.* may, on livings where the rector or vicar does not personally reside four months in the year at least, grant the use of the rectory or vicarage house, and the garden and stable thereto belonging, such use to be granted to the said curate for the space of twelve calendar months by the authority of the ordinary, under his hand and seal, with power in the said ordinary to renew and grant from time to time, or a further sum, not exceeding 15*l. per ann.* in lieu of such house, garden, and stable, in case there shall be none such, or it shall appear to him not to be convenient to allot and assign the same to such curate. Provided that the said house, garden, and stable, shall be for the use of the said curate and his family only during his *actual* residence in the said rectory and vicarage house. Provided also, that the ordinary shall have power at any time under his hand and seal, to revoke the grant to the said curate of the said house, garden, and stable, or any of them, and also to insert in such grant such terms and conditions to be observed on the part of the curate as he shall think reasonable.

By the faculty of dispensation, a pluralist is required, in that benefice from which he shall happen to be most absent, to preach thirteen sermons every year; and to exercise hospitality for two months yearly, and for that time, according to the fruits and profits thereof, as much as in him lieth, to support and relieve the inhabitants of that parish, especially the poor and needy.

By the 1 W. c. 26. if any person presented or nominated by either of the universities to a popish benefice with cure, shall be absent from the same above the space of sixty days in any one year; in such case, the said benefice shall become void. Burn's Eccl. Law, art. *Residence.*

Residence, in *Chemistry*, &c. the *settling*, or what remains of a liquor, or other substance, in the vessel after the chief part of it has been poured or taken out, to change the manner of the operation on what is left.

Residence, *Country*, in *Ornamental Gardening*, a rural habitation, mansion, or other kind of place, where it, as well as the ground which surrounds it, are formed and laid out in some sort of ornamental style. There have been a great many ways of accomplishing this proposed at different times, which have given rise to the variety of styles that have prevailed at different periods; but the *avowedly formal*, and the *affectedly graceful*, are the two which have been chiefly had recourse to, according to the writer of the "Treatise on Country Residences," before that of the free, characteristic, natural one, which he has suggested the introduction of; which is confined to no particular style or mode, but which furnishes and supplies beauties and effects which are suitable to the scene and situation, whatever the age or country may be from which they are borrowed, or by whatever epithets they may be called or known.

Suppose a piece of ground containing from four to five hundred acres, of which more than three hundred are to be formed into a residence; that a brook may pass through it, partly among meadows or wastes of copse and pasture, and partly along the hedge fences; that two farm-houses, some cottages, and belts of planting may likewise appear; that the farm-house in the centre is on the highest ground, which descends in varied and gentle slopes on every side to the margin of the brook, except toward a cluster of cottages upon the banks of it, where it abruptly terminates in a wooded precipice of rocks or gravel, or something of a similar kind.

The manner of forming a residence, in such a situation, according to the ancient formal style of a century ago, would, in the first place, have been to clear away every cottage, hedge, and tree; then to level down the precipice, and all irregularities. After which to form it into square fields and avenues, planting belts of trees between them. Two small woods would have been placed on each side of the house, and a large one near the garden. The water of the brook would have been introduced through a conduit, to an oblong canal; from that to two round basins in the central garden; thence to another oblong canal answering to the first. From that, under ground, as before, to two ponds in the large wood; after which to be carried by the side of the outer strip of plantation until it rejoined the former canal. The other parts are not very material. But it may be noticed that the surrounding fields would have nothing done to them, but the removal of the cottages, and the belt of planting, which would otherwise have closed the view from the avenue. The short avenues would probably be continued through the fields in single rows of trees.

And according to the affectedly graceful, or more modern style of Brown and his followers, the same portion of land would have been laid out by means of clearing, levelling, and smoothing the irregularities of the surface in the first instance, only leaving a single small cottage properly hidden by the belt of planting. The house would be built on the highest part of the ground. The whole of the offices sunk under or below it, with the exception of the stables; and the part of the house which is seen, in the form of a cube, with a large front, visible only on the side on which is the approach. The brook elevated upon the side of the rising ground, and formed into a still river, with cascades and islands, which are capable of being seen all round from the house. The park surrounded with a belt, inclosing a ride or drive within this, the whole diversified with clumps of various sizes, but mostly similar in shape. The park fed with deer, sheep, and cattle, and the more considerable spaces in the drive, with the whole of the pleasure ground, regularly mown. Buildings would be introduced in various places in the drives as well as the park. The approach and walks formed in different turns and windings, and the pleasure ground, and kitchen garden, in a regular manner, the latter mostly in the perfectly square form. From each of the drives, the approach, walks, and the pleasure ground, the objects of view are either the ornamental buildings or the mansion, vistas being made in all places from the one to the other; the belt excludes the whole of the distant country from the lower parts of the ground, and the clumps from the higher, as well as from the houfe. It may be fuppofed that nothing would be done to the furrounding country, only, perhaps, that in the place of the removed cottages, a formal ftreet, under the title of improved village, might be formed and raifed at a fuitable diftance from the manfion and its approach. It is fuggefted that numbers of places in this country, as well as in Scotland, are laid out nearly in this manner; and that the general paftures, the *belt*, the *clump*, the *tame* and *ftill* river, abound in both countries, and continue to be formed in the fame way, whatever may be the natural character of the fituation or place.

But according to the characteriftic or natural manner which the writer has advifed, fuch a fituation fhould be laid out fomewhat in this way. The houfe fhould be placed on the abrupt termination of the rifing grounds, the whole of the offices be brought more or lefs into view, each of fuch buildings being made low, irregular, and fuitable to the nature of the ground. The brook be rendered more characteriftic as fuch, by having little aits and iflands formed in it, as well as occafional pools, or ftagnated fpots of water, in the open parts, and under the fhade of the grove where not feen. Near the houfe, in the hollow, it fhould fpread out in the manner of a lake, being varied by prominences, iflands, and wood. The ftable offices, kitchen garden, and farm, fhould be placed near each other, and at no great diftance from the main refidence. The wood fhould be feen in one extenfive irregular mafs, crowning the large eminence, and connecting it with the lower grounds in which the brook runs. Inftead of furrounding the whole with a belt of planting, the borders of the park fhould every where blend in an irregular manner with the country; in fome places a hedge only, in others a funk fence, and in a few open paling fhould feparate it from the corn-fields; in different places large portions of it may be united to the country by means of hurdle fences, in which way more or lefs of it may be inclofed and let out to tenantry as thought proper. In this mode, the wood does not terminate abruptly with the park; but gradually lofes itfelf in fcattered trees, hedge-rows, and occafional ftrips among the corn lands of the neighbouring farms. Hence, it is fuggefted, arife the beauty of the views in walking round the outfide border of the park. An irregular village fhould be formed by fcattered cottages, wood, and pafture, from which the approach is led to the houfe; with a branch to the offices and the garden; the farm road is moftly concealed, but might often be partially feen with advantage. Walks fhould be formed in different parts of the grounds; thofe for morning and evening fhould be extenfive and open; thofe for noon wholly under the wood. They both afford confiderable variety, whether the beauty and wildnefs of the park, the views of the diftant corn-fields and hedge-rows, the village, the brook, or the different picturefque compofitions formed by the houfe and offices be regarded; without faying any thing concerning diftant profpect, which, in the other practice, is often loft by the belt, and at all events conftantly prevented from harmonizing with the park, by its dark diftant boundary. The cattle may be guarded and kept off from the front of the manfion by fome proper fort of fence, and a certain fpace along the border and rivulet be preferved as pleafure ground, in which exotic fhrubs and flowers may be planted in difperfed natural-like groups and thickets. The whole of the other parts of the ground may be fed with cattle, horfes, deer, and fheep, as well as other animals. The kitchen garden, in fuch a fituation, need not be fo large as in other cafes, as many culinary vegetables may be grown in other places, and the fields of the farm. Nor will an orchard be neceffary in many cafes, as a fufficient number of fruit-trees may be introduced in the groups, and pleafure-ground fcenery. There may, befides thefe, be fome other differences made, which need not be noticed in this place. A drive may be made through the park as thought proper, and through the furrounding country according to the circumftances of it as connected with the park. The planting in the park fhould abound with low growths and wildneffes, in the nature of the trees and the various maffes of wood in it.

The fame fpot of ground is difplayed as formed and laid out after thefe three different methods, in the work already alluded to, which may be confulted with much advantage by the inquirer on this head.

In comparing the leading diftinctions between the two latter of the above methods of forming and laying out rural refidences, or that followed by Brown, Repton, and others, and that which has been fuggefted by the writer; it is remarked that, in relation to the *whole*, the object of the *former* is to render a refidence feparate from the country; while the *latter*, or the characteriftic ftyle of forming, and the improvements propofed in refidences already formed on bad principles, tend to harmonize it. In relation to the parts, that fort of gardening forms and places every thing diftinctly and alone; while this groups and connects them with each other, and with the whole.

In what regards *wood*, the vulgar practice is, it is faid, to fhut out the country by a belt, and to vary the fpace within by the clumps: while that which is propofed tends to increafe the expreffion and character of the fituation or place, whatever part of the grounds it may direct to be wooded, whether in the middle or the boundaries; and inftead of fhutting out the country, the wood diverges in a gradual manner into hedge-rows, fo as to unite and harmonize it as much as poffible with the refidence.

In refpect to *buildings*, the former or common way is to conceal every thing except the manfion: while this, on the contrary, fhews every building, not as fingle objects, but as compound parts of the fcenery of the place.

In relation to *water*, the old or former plan is to produce quantity or extent of furface, and to render it as confpicuous as poffible: while the ftyle here propofed is to produce natural character.

In refpect to *ground*, the former or modern fyftem is to fmooth and form undulating furfaces: while that of this is to attend to natural character.

In what regards *parks*, modern landfcape gardening, it is faid, makes them fmooth and deftitute of under-growths, ferns, and other plants: while this, by introducing hollies, thorns, briars, ferns, and fometimes furze, broom, and brambles, gives them a wild foreft character, which is the great and main object of their formation and arrangement.

In refpect to *pleafure-ground*, the common mode, it is faid, is to form many acres of lawn, which are to be kept in prefervation at a great expence, while they produce nothing. The plan here propofed admits of more or lefs, according to circumftances and fituation, but generally forms little that is not grazed by fheep or covered by flowers, extenfive mowing being therefore never requifite, and it commonly permits the cattle to come within a fmall diftance of the refidence.

The difference of expence will, it is fuppofed, be very confiderable, as muft be evident from the general confideration of the difference between affifting what Nature has already begun, and counteracting her altogether. This will be fo whether it relates to the manfions, buildings, planting, water, gardens, farms, or pleafure-grounds. And there will be differences

differences of a minor nature on all these heads, as well as on many others.

The ideas respecting the latter of these methods of forming and laying out residences of this nature, have yet been but little put in practice, nor their union in the mind of any one person been such as to produce a distinct style in regard to them, except, perhaps, with the writer of the work before alluded to. They are, however, of considerable importance, and highly deserving of attention, not only as being founded on the principles of nature, but as according so well with the nature of rural scenery.

In chusing situations for residences of this description, it is advised, that attention should be particularly paid to such as are most convenient in what respects scite and position, as they relate to the adjoining country; that they should be the most striking which the grounds will afford; and that they should furnish the best views from the residences of the surrounding country which it is capable of supplying.

A perfect knowledge of what is deficient, and whether that which is wanted can be supplied by the proposed scite, or is wholly wanting, or some others deficient that cannot readily be afforded, will greatly contribute to the decision of the first point. And much assistance, in some respects, may often be derived from the neighbouring residences, especially as to climate, weather, springs, rivulets, roads, markets, and many other similar particulars; though they can mostly be ascertained with little trouble in other ways.

In regard to the next point, it is of very great importance, as the effect depends much upon it. Where the surfaces are only gently varied, some of the highest eminences may be mostly fixed upon for this purpose. But where they are varied in a high degree, and where a number of hills are within the proposed space: if such hills slope gently, some of their sides may commonly be selected for this use; or, when they are very steep, it may be upon some gentle rising or eminence near their bottom parts. Occasionally, where rivers pass through the grounds, it may be on some of their banks, where they are rendered interesting either by rocks, bends, or other similar means. Where there are lakes, the margins of them may be proper for the purpose, as producing good effects in such cases; and the rocky margins of the sea, in some instances, may be very suitable. Many other appropriate situations for this purpose might be noticed, but these may shew the nature of striking ones, and the means of selecting them.

The proper accomplishment of this object is very material, as any error in it may be highly injurious in various ways; while its being properly done saves expence, and at the same time affords a far superior effect, as is seen in a variety of instances.

In respect to the last matter, or that of the views towards the surrounding scenery being agreeable, it is supposed to be the best accomplished by the proper arrangement or disposition of the apartments of a residence. Where regularity is to prevail this cannot always be so easily done, but where the irregular is had recourse to, which should mostly be the case in this sort of residence, there can be little difficulty in effecting it, either by means of projections or recesses.

Thus, the breakfasting room should front a morning scene, and afford a prospect somewhat inviting to exercise throughout the day; the drawing room should have such a disposition as to display the effects of the setting sun, &c. In short, to every view, some object, it is supposed, should appear sufficiently striking to characterise it; as a hill, a spire, or some other thing of a similar nature; as, unless this be the case, too trifling an impression is left upon the mind. All these matters, it is supposed, are the best decided upon the particular spots where they should be marked out and left for the observations of others, with the view of their being afterwards finally settled. They should never be determined upon in the closet of the designer.

In forming residences of this nature, the style of the buildings should, in some measure, it is thought, be adapted to, or regulated by, the nature of the place, and the general growth of the trees in it; the forms of the particular trees which may be peculiar to it; the general character of the surrounding scenery; and the colour of the rocks, as well as of the ground. It is found that the more common sorts of trees, in their natural growth, whether single or in groups, deviate a little in their general form, and the delicacy of their parts, according as their situation may be. Thus, where much exposed, they are mostly broad and low, being more hardy, rough, and picturesque, than when covered with young shoots, which are comparatively soft, fresh, and beautiful. In high rocky spots and exposures, trees are much broken, or divided into parts, and distant from each other, but apparently firmly attached to the place; these are hardier than others, with much less softness and beauty. In low fertile plains, trees are mostly large and erect, throwing out their branches on all sides; the foliage is full and fresh; and the whole outline round, full, and flowing. When single in this sort of situation, the balance of the branches in the trees is better preserved, than in the contrary cases. Where vallies are confined between hills, trees grow high and upright, rarely broad, or putting forth many horizontal branches: the growth is quick; the shoots and foliage are tender and delicate; the trunk comparatively slender; and the whole trees more elegant and capable of graceful motions than in any of the former situations or aspects.

It is supposed that these different circumstances in the growth of trees may easily suggest styles of building somewhat analogous in their general magnitude, height, and finishing. On rocky exposed spots, where trees grow low and irregular; low irregular edifices in the castle style may be raised. In vallies, where they grow high and elegant, houses in the tower style, which implies much height, should commonly be had recourse to. In rich extended plains, buildings of the Grecian order, or such as are in a more massy and regular style than the others, should be formed. "This mode is," it is said, "certainly deserving of attention, were it for no other reason than that the trees might group well with the buildings; that when full grown they might neither be too large, nor too small; that they might neither diminish it into insignificance, nor leave it staring through trees, which, from want of due proportion to it, appear as copsewood." Many instances of these different evils are to be met with in different places.

And it is noticed, that this mode of fixing on the style of residences of this kind must be attended to, though trees be not growing on the situations at the time of forming and raising them. This is to be determined in such cases, by the nature of the climate and the qualities of the soil, as the growth of trees chiefly depends upon them.

With regard to the forms of trees, most places are capable of affording common ones, such as oaks, elms, beeches, and others of similar kinds. But there are many spots, where residences of this sort may be formed, that are only capable of raising certain descriptions to the state of trees. This frequently occurs in hilly and maritime situations; which therefore require the particular attention of the designer; as the kinds of trees that suit them are so very different from the ordinary sort, that if he were to be attempting to group with oaks and beeches, he might be grievoufly difappointed, as not any would probably grow, but fpiry larches, dark Scotch firs, birches, and mountain afh, or perhaps only ivy and elder. This may furnifh a variety of ufeful hints to the defigner, as well as others.

The general character of the furrounding fcenery is equally deferving of attention as the trees, and fhould concur in deciding on the ftyle of the refidence. It is a common notion that buildings fhould form ftrong contrafts to the works of nature, from which various ftyles of them have been fuggefted under different circumftances; but more full inquiry will fhew that very fudden contrafts are not found in general nature, though they may accidentally occur in fome cafes, confequently that they are highly improper to be ufed in this way.

With refpect to the colour of the rocks, and the ground, it is faid, that, not merely the general forms of the furface, but the appearances of the foil and the rocks, fhould deferve attention, as contributing greatly to promote the principle of harmony. The tints of rocks, ftones, gravel, and the foil, are moftly the fame in one part of the country. Where they agree with the colour of the refidence, the effect muft, it is fuppofed, be fingularly happy, as feen in the works of painters, as well as in the ancient refidences of the country kind. But where they difagree, it muft be difgufting, as is feen in many cafes of white-wafhing buildings in rocky fituations. This furnifhes hints which may be ufeful in managing that procefs to the moft advantage in other cafes; and others are likewife thrown out upon different matters, which are equally ufeful. But the defigner is cautioned againft carrying thefe, or any other notions, into the extreme, contrary to the common practice; as where the expreffion of gaiety, or ftriking beauty, is defirable, no reafons fuggefted from the colour of the rocks or foil are intended to hinder the production of thefe characters, if in general harmony with what furrounds them.

There are many other matters which relate to the fubject, that are forcibly pointed out, and the means of executing them well explained, in the work alluded to above, fuch as the methods of uniting refidences of this fort with the grounds by means of the offices and appendages of other kinds; and with the furrounding country or fcenery by the former, as well as by architectural appendages principally of the ornamental defcription. Alfo as to the modes of executing and finifhing them.

More full information on the whole of this fubject may be obtained from the above treatife, and the writings of Knight, Price, and others on the fame head.

RESIDENT, a public minifter, who manages the affairs of a king in the court of a prince, or petty ftate; or the affairs of a prince, or petty ftate, in the court of a king or prince.

Thus, the king of England has refidents in the courts of the electors, and other princes of Germany and Italy; at the republics of Genoa and Lucca; and they, reciprocally, have refidents in the court of Great Britain.

Refidents are a clafs of public minifters inferior to ambaffadors and envoys; but, like them, they are under the protection of the law of nations.

The refident does not reprefent the prince's perfon in his dignity, but only in his affairs. His reprefentation is in reality of the fame nature as that of the envoy; and he is accordingly, together with the envoy, often termed a minifter of the fecond order; and thus the public minifters are diftinguifhed only into two claffes; ambaffadors, who have the reprefentative character, fo termed by way of excellence, and all the minifters who are not invefted with that eminent character.

RESIDENT, *Refidens*, in our *Ancient Cuftoms*, was a tenant who was obliged to refide on his lord's land, and not to depart from the fame, called alfo *homme levant* and *couchant*, and in Normandy *reffeant du fief*.

"Quantumque de aliis teneat, ei magis obnoxius eft; & ejus refidens effe debet, cujus legius eft." Leg. H. I.

RESIDENTIARY, RESIDENTIARIUS, a canon inftalled to the privileges and profits of refidence.

RESIDUAL ANALYSIS, is a branch of algebra invented by Landen, and applied to the folution of thofe problems ufually folved by means of the differential and integral calculus, or the direct and inverfe method of fluxions; by which the ingenious author thought to be able to avoid the objections generally made to the new calculus under either of the above forms. With regard to the fluxional procefs, he thought it more free from objection than the differential calculus; although many important ones might be difcovered in it. However natural, fays the author, it may be, in certain problems, to confider fuch magnitudes as enter therein, to be generated by motion, it feems very unnatural to bring motion into confideration in the folution of queftions purely algebraical. Nor does it feem natural in the folution of problems concerning the motion of bodies, to fuperinduce imaginary motions, and thereby bring into confideration the velocity of time, the velocity of velocity, &c.; nor yet does it appear more natural, in the refolution of other problems, to make ufe of the fluxionary method, when (as is moft commonly the cafe in that doctrine) the fluxions introduced into the procefs can, only in a figurative fenfe, be faid to be the velocities of increafe of the quantities called their fluents; fuch figurative expreffions not being the natural language of analytics, but frequently, inftead of conveying clear and diftinct ideas, are confufedly employed in treating of quantities as generated by motion, which in reality cannot be conceived to be fo generated. That thefe are legal objections to the doctrine of fluxions we are not difpofed to deny; but it is now generally admitted, that the defect of the fluxionary calculus is by far lefs than that which has place in the refidual analyfis, which M. Landen was defirous of fubftituting for it. Indeed, we believe its defects were fo obvious, that few, if any, mathematicians were induced to make it the foundation of any of their inveftigations; and it would, therefore, be ufelefs for us to occupy our pages in explaining the principles on which the author refted his calculus. We fhall, therefore, merely obferve, that in this analyfis, a geometrical or phyfical problem is reduced to another purely algebraical; and the folution is then obtained without any fuppofition of motion, and without confidering quantities as compofed of infinitely fmall particles.

Inftead of finding the fluxion of a variable quantity, in the refidual analyfis, the author proceeds by taking the difference of the fame function of the variable, in two different ftates of that quantity, and expreffing the relation of this difference to the difference between the two ftates of the variable quantity itfelf. This relation, being firft expreffed generally, is then confidered in the cafe in which the difference of the two ftates of the variable quantity is equal to zero.

Thus when, in the fluxionary calculus, it would be neceffary to find the fluxion of fuch a quantity $v^{\frac{m}{r}}$, which is $\frac{m}{r} v^{\frac{m-r}{r}} \dot{v}$, M. Landen takes the quotient of $\frac{v^{\frac{m}{r}} - w^{\frac{m}{r}}}{v - w}$, when

when $v = w$, and finds it to be $\frac{m}{r} v^{\frac{m-r}{r}}$, as above; and in the ſame manner he determines what is commonly called the fluxions of a^x, x^x, log. x, &c.

The firſt book of the reſidual analyſis was publiſhed in 1764, which contains its application to a variety of algebraical inquiries, and in determining the tangents, evolutes, ordinates, points of contrary flexure, double and triple points, &c. And in the ſecond book it was intended to ſhew its application in a variety of mechanical and phyſico-geometrical inquiries; but, for ſome reaſon not known, that book was never publiſhed.

RESIDUAL *Figure*, in *Geometry*, the figure remaining after ſubtraction of a leſſer from a greater.

RESIDUAL *Root*, is a root compoſed of two parts or members, only connected together with the ſign $-$.

Thus, $a - b$, or $5 - 3$, is a reſidual root; and is ſo called, becauſe its true value is no more than its reſidue, or difference between the parts a and b, or 5 and 3.

RESIDUARY LEGATEE. See LEGATEE.

RESIDUE, RESIDUUM, the remainder or reliqua of an account, debt, or obligation.

RESIDUUM *of a Charge*, in *Electricity*, firſt diſcovered by Mr. Gralath, in Germany, in 1746, is that part of the charge that lay on the uncoated part of a Leyden phial, which doth not let go all its electricity at once; ſo that it is afterwards gradually diffuſed to the coating.

RESIDUUM *of an Inteſtate's Effects*. See INTESTATE. See alſo EXECUTOR, and *Reſiduary* LEGATEE.

RESIGNATION, in *Ethics*, is a moral virtue, which ſuperadds to patience a ſubmiſſive diſpoſition, reſpecting the intelligent cauſe of our uneaſineſs. It acknowledges both the power and the right of a ſuperior to afflict: it is uſually connected with a confidence in his juſtice, and indulges a hope alſo in ſome future exemption, and thus it oppoſes a fretful repining temper of mind.

RESIGNATION, *Reſignatio*, in the *Canon Law*, the ſurrender or giving up of a benefice into the hands of thoſe from whom it was received.

Reſignation is of equal import with *ſurrender;* only the former is reſtrained to ſpiritual benefices, and the latter to temporal offices or employments.

It is a maxim in the eccleſiaſtical law, that all reſignations muſt be made to ſome ſuperior (Gibſ. 822.); therefore a biſhop muſt reſign, not to the dean and chapter, but to his metropolitan, from whom he received confirmation and conſecration; but the archbiſhop can reſign to none but the king himſelf.

Reſignation muſt be made to the next immediate ſuperior, and not to the mediate; as of a church preſentative to the biſhop, and not to the metropolitan. (2 Roll. Abr. 358.) Donatives are not reſignable to the ordinary, but to the patron who hath power to admit; and if there be two patrons of a donative, and the incumbent reſign to one of them, it is good for the whole. Regularly, reſignation muſt be made in perſon, and not by proxy. It is uſually done either by perſonal appearance before the ordinary, or elſewhere before a public notary, by an inſtrument directed immediately to the ordinary, and atteſted by the ſaid notary, in order to be preſented to the ordinary by a proper perſon, who may pray his acceptance. No reſignation can be valid, till accepted by the proper ordinary; that is, no perſon appointed to a cure of ſouls can quit that cure, or diſcharge himſelf of it, but upon good motives, to be approved by the ſuperior who committed it to him; for it may be, that he would quit it for money, or to live idly, or the like. Nor is there any pretence to ſay, that the ordinary is obliged to accept; ſince the law hath appointed no known remedy if he will not accept, any more than he will not ordain. 1 Still. 334.

Lindwood makes a diſtinction in this caſe, between a cure of ſouls, and a ſine-cure. The reſignation of a ſine-cure, he thinks, is good immediately, without the ſuperior's conſent; becauſe none but he that reſigneth hath intereſt in that caſe: but where there is a cure of ſouls, it is otherwiſe, becauſe not he only hath intereſt, but others alſo unto whom he is bound to preach the word of God; wherefore, in this caſe, it is neceſſary that there be the ratification of the biſhop, or of ſuch other perſon as hath power by right or cuſtom to admit ſuch reſignation. (Gibſ. 823.) After acceptance of the reſignation, lapſe ſhall not run but from the time of notice given. The church, indeed, is void immediately upon acceptance, and the patron may preſent, if he pleaſe; but as to lapſe, the general rule that is here laid down is the general doctrine of all the books: inſomuch that if the biſhop, who accepted the reſignation, dies before notice given, the ſix months ſhall not commence till notice is given by the guardian of the ſpiritualities, or by the ſucceeding biſhop, with whom the act of reſignation is preſumed to remain. Gibſ. 283.

Reſignations are either *ſimple* or *conditional*.

RESIGNATIONS, *Simple* or *Pure*, are thoſe by which the incumbent ſtrips himſelf of all his right, abſolutely, and without any conditions, or reſerve of penſion. Theſe are made to the biſhop, or ordinary.

By the 31 Eliz. cap. 6. § 8. if any incumbent of any benefice, with cure of ſouls, ſhall corruptly reſign the ſame, or corruptly take for, or in reſpect of reſigning the ſame directly or indirectly, any penſion, ſum of money, or other benefit whatſoever; as well the giver, as the taker, ſhall loſe double the value of the ſum given or received; half to the queen, and half to him that ſhall ſue for the ſame. Before the ſtatute, the biſhop, in caſes of reſignation, might, and did frequently, aſſign a penſion, during life, out of the benefice reſigned, to the perſon reſigning. But by the aforeſaid act, no penſions whatſoever can be reſerved. But a man may bind himſelf by bond to reſign, and it is not unlawful. For bonds of reſignation, ſee SIMONY.

RESIGNATIONS *in Favour*, or *Conditionol Reſignations*, are ſuch as are only made on condition that ſuch other perſons ſhould be inveſted with them; ſo that the reſignations are null, unleſs the conditions be punctually executed. Theſe reſignations *in favorem* are not of above two hundred and fifty years ſtanding. Strong oppoſition was at firſt made to them, they being eſteemed a kind of ſucceſſion or tranſmiſſion of benefices, as of patrimonies belonging to a family. Accordingly, theſe reſignations are not made into the hands of the ordinary, or collator, as pure reſignations are, but to the collator paramount, who in the Romiſh church is the pope; there being a ſuſpicion of ſimony or other unlawful paction therein, where admitted of in prejudice to the lay patron.

RESIGNEE, in *Law*, the party to whom a thing is reſigned.

RESINS, in *Chemiſtry* and the *Arts*, peculiar inflammable compounds, furniſhed by ſome vegetables, and in ſome caſes by animals.

Agreeably to what we have obſerved under OILS, all bodies coming under the head of the latter, although perfect liquids in their ordinary ſtate, are ſuſceptible of a ſolid form, by long expoſure to the air, and more ſpeedily by expoſure to bodies furniſhing oxygen with facility. Thoſe oils we term fat oils, ſuch as olive, ſpermaceti, rape, &c. by treating with nitric acid, become ſolid like tallow, and poſſeſs

possess similar properties. The oils termed *drying*, such as linseed and nut-oil, by the presence of oxygen, assume a solid form, unlike the greasy substance afforded by the fat oils, and more like horn, or elastic gum (caoutchouc.) The volatile oils are susceptible of the same change, from liquidity to solidity, by the agency of oxygen; the result being resins, which differ from each other in nothing material, excepting their degrees of solidity, and their peculiar odour. If we are to conclude that every essential or volatile oil is capable of being converted into a resin, which is highly probable, the number of resins will be very great. Indeed the known species are vastly too numerous for our notice in this place: we shall, therefore, confine our attention to a few of the most particular resins, especially those which are valuable in the arts, and in medicine. Dr. Thomson gives the following list of resins, with the names of the vegetables from which they are obtained.

1. Turpentine of Chio, from the pistacia terebinthus.
2. Venice turpentine.
3. Strasburgh turpentine, from the common fir.
4. Pitch, from the pinus picea.
5. Elemi, from the amyris elemifera.
6. Mastic, from the pistacia lentiscus.
7. Sandarach, from the juniper.
8. Guaiac, from the guaiacum officinale.
9. Laudanum, from the cistus ladaniferus.
10. Dragon's blood, from the dracæna draco.
11. Balsam of Mecca, from the amyris opobalsamum.
12. Balsam of Copahu, from the copaifera officinalis.

To these may be added,

13. Balsam of Canada, from the pinus balsamea.
14. Guaiacum, from the lignum vitæ.
15. Copal, from the copallinum of North America.

Some of the resins are combined with benzoic acid, by which their properties are altered: of these are benzoin, balsam of Tolu, balsam of Peru, and storax.

Another class of these bodies are combined with gum, and hence have been called *gum resins*: of these are olibanum, galbanum, scammony, assafœtida, myrrh, ammoniac, aloes, and opium. They admit of analysis, either by separating the resinous part by alcohol, or the gummy part by water.

These latter substances are used in medicine. Some of the first class, or the pure resins, are used as cements; and their solution in alcohol constitutes a variety of useful varnishes.

Those resins which are distinguished by the name of balsams are said to be such as contain benzoic acid. It appears, however, they have also been distingushed for their liquidity, and from their excess of odour; so that at present the phrase appears to be very indefinite. See BALSAM.

The resins are of various degrees of consistence and hardness. The balsams of Canada and Mecca are thickish fluids: the former is often so liquid as to be spread with a brush, and is sometimes used for varnishing pictures. It gradually hardens, on exposure to the air, and ultimately may be rubbed with the hand without soiling.

Others of the resins become hard with very little exposure to the air, and are found in hard tears, sticking to the tree which affords it: of these are mastic, sandarach, and copal. Those which do not easily become solid may be obtained in that form, by distilling off the thin part. Resin and pitch are obtained in this way: the former is obtained by distilling turpentine, the latter by distilling tar. Tar is no other than turpentine contaminated with the soot, which is produced by the partial combustion employed for its extraction from the wood.

All the resins become harder by exposure to a moderate heat. It is upon this fact that the art of the japanner depends. If the surface to be japanned be covered with common tar only, and exposed to the temperature of 300° for a length of time, the coating becomes hard and infusible. At the same temperature, any other resin applied in the same way, would assume a similar hardness.

Some animals and minerals, as well as the vegetables, afford resins, or bodies very analogous to them. The concrete part of the bile of animals has most of the properties of a resin, and shell-lac is furnished from the insect called *coccus lacca*.

Ear-wax is also found to have the properties of a resin; and the substances well known as perfumes, castor, civet, and musk, are no other than animal resins. For the particular application of resins to *varnishing* and *japanning*, see those articles.

Resins are employed for many purposes. Those of the cheapest kind are used for torches, and to cover the outsides of ships and boats. The fine transparent resins compose varnishes. Many of them are employed medicinally: such are those which enter into the composition of ointments and plasters; or internally, as the resins of scammony, jalap, and turpeth, which are purgative. Other resins, the smell of which is agreeable, as benjamin and storax, are employed as perfumes.

RESIN, *Elastic*. See CAOUTCHOUC.

RESIN, *Mastic*. See MASTIC.

RESISTANCE, or RESISTING *Force*, in *Physics*, any power which acts in opposition to another, so as to destroy or diminish its effect.

Of resistance there are various kinds, arising from the various natures and properties of the resisting bodies, and governed by various laws: as the resistance of solids, the resistance of fluids, the resistance of the air, &c.

RESISTANCE *of Solids*, in *Mechanics*, is the force with which the quiescent parts of solid bodies oppose the motion of others contiguous to them.

Of this there are two kinds. The first, where the resisting, and the resisted parts, *i. e.* the moving and quiescent bodies, are only contiguous, and do not cohere; *i. e.* where they constitute separate bodies or masses.

This is what M. Leibnitz calls *resistance of the surface;* but which is now more commonly denominated friction; for the laws of which, see FRICTION.

The second case of resistance is where the resisting and resisted parts are not only contiguous, but cohere; *i. e.* are parts of the same continued body or mass; for the phenomena and laws of which, see COHESION.

To which we may also add, the resistance which takes place between surfaces of solids, when completely in contact, though not forming one and the same body, or the resistance they offer to separation, the particulars of which are treated of under the article ADHESION.

RESISTANCE *of the Fibres of solid Bodies, Theory of the.* To form an idea of this resistance or renitency of the parts, suppose a cylindrical body suspended vertically by one end. Here all its parts, being heavy, tend downwards, and endeavour to separate the two contiguous planes, where the body is the weakest; but all the parts resist this separation by the force with which they cohere, or are bound together. Here then are two opposite powers; *viz.* the weight of the cylinder, which tends to break it; and the force of cohesion of the parts, which resists the fracture.

If the base of the cylinder be increased without increasing its length, it is evident the resistance will be increased in the same ratio as the base; but the weight also increases in the same ratio: whence it is evident, that all cylinders of the ſame matter and length, whatever their baſes may be, have an equal reſiſtance, when vertically ſuſpended.

But if the length of the cylinder be increaſed, without increaſing its baſe, its weight is increaſed, while the reſiſtance or ſtrength remains the ſame: conſequently it is weakened by its additional length, and has a greater tendency to break.

Hence, to find the greateſt length a cylinder of any matter may have, to break with its own weight; it is only neceſſary to know what weight is juſt ſufficient to break another cylinder of the ſame baſe and matter: for the length of the required cylinder muſt be ſuch, that its weight may be equal to the weight of the firſt cylinder, together with the additional weight that was employed in producing the ſeparation.

Thus let l denote the firſt length of the cylinder, c its weight, g the given weight the lengthened cylinder is to bear, and w the leaſt weight that breaks the cylinder l, alſo x the length ſought: then as $l : x :: c : \frac{cx}{l} =$ the weight of the longeſt cylinder; and this, together with the given weight g, muſt be equal to $c + w$: hence then, $\frac{cx}{l} + g = c + w$; or $x = \frac{c + w - g}{c} l =$ the length ſought. When the cylinder is juſt to break with its own weight only, then $g = 0$, and the expreſſion is ſimply $x = \frac{c + w}{c} l$.

If one end of the cylinder were fixed horizontally into a wall, and the reſt ſuſpended thence, its weight and reſiſtance would then act in a different manner; and if it be broke by the action of its weight, the rupture would be at the end fixed into the wall. A circle or plane contiguous to the wall, and parallel to the baſe, and conſequently vertical, would be detached from the contiguous circle within the plane of the wall, and would deſcend. All the motion is performed on the loweſt extremity of the diameter, which remains immoveable, while the upper extremity deſcribes a quadrant of a circle, and till the circle, which before was vertical, become horizontal; *i. e.* till the cylinder be entirely broken.

In the fracture of the cylinder it is viſible two forces have acted, and the one has overcome the other: the weight of the cylinder, which aroſe from its whole maſs, has overcome the reſiſtance which aroſe from the largeneſs of the baſe; and as the centres of gravity are points in which all the forces, ariſing from the weights of the ſeveral parts of the ſame bodies, are conceived to be united, one may conceive the weight of the whole cylinder applied in the centre of gravity of its maſs, *i. e.* in a point in the middle of its axis: and the reſiſtance of the cylinder applied in the centre of gravity of its baſe, *i. e.* in the centre of the baſe; it being the baſe which reſiſts the fracture.

When the cylinder breaks by its own weight, all the motion is on an immoveable extremity of a diameter of the baſe. This extremity, therefore, is the fixed point of a lever, whoſe two arms are the radius of the baſe, and half the axis; and, of conſequence, the two oppoſite forces do not only act of themſelves, and by their abſolute force, but alſo by the relative force they derive from their diſtance with regard to the fixed point of the lever.

Hence it evidently follows, that a cylinder, *e. gr.* of copper, which, vertically ſuſpended, will not break by its own weight, if leſs than four hundred and eighty fathom long, will break with a leſs length in an horizontal ſituation; becauſe the length, in this latter caſe, contributes two ways to the fracture; both as it makes it of ſuch a weight, and as it is an arm of a lever to which the weight is applied. Hence, alſo, the ſmaller the baſe is, the leſs length or weight will ſuffice to break it; both becauſe the reſiſtance is really leſs, and becauſe it acts by a leſs arm of a lever.

Hence, to find the length a priſm will bear, when fixed in an horizontal poſition, before it breaks, either by its own weight, or by the addition of any adventitious weight; take any length of ſuch a priſm, and load it with weights till it break; then put

l = the length of this priſm,
c = its weight,
w = the weight that breaks it,
a = the diſtance of the weight w,
g = any given weight to be borne,
d = its diſtance,
x = the length required to break it.

Then $l : x :: c : \frac{cx}{l}$, the weight of the priſm x; and $\frac{cx}{l} \times \frac{1}{2} x = \frac{cx^2}{2l}$ = its momentum; alſo dg = the momentum of the weight g; $\frac{cx^2}{2l} + dg$ = momentum of the priſm x, and its additional weight g.

In like manner we have $\frac{1}{2} cl + aw$, for the momentum of the ſhorter priſm, together with the weight w.

Conſequently we obtain the following equation:

$$\frac{cx^2}{2l} + dg = \tfrac{1}{2} cl + aw;$$

from which is found $x = \sqrt{\frac{(aw + \frac{1}{2}cl - dg)\,2l}{c}}$, the length ſought, or that by which the cylinder will break with the weight g, at the diſtance d. If this laſt weight be nothing, or the length be required when the cylinder would juſt break with its own weight, then we ſhall have $dg = 0$, and the expreſſion becomes ſimply $x = \sqrt{\frac{(aw + \frac{1}{2}cl)\,2l}{c}}$.

If two cylinders of the ſame matter, having their baſes and lengths in the ſame proportion, be ſuſpended horizontally; it is evident, that the greater has more weight than the leſſer, both on account of its length, and of its baſe. But it hath leſs reſiſtance on account of its length, conſidered as a longer arm of a lever, and has only more reſiſtance on account of its baſe; therefore it exceeds the leſſer in its bulk and weight more than in reſiſtance, and conſequently it muſt break more eaſily.

Hence, we ſee why, upon making models and machines in ſmall, people are apt to be miſtaken as to the reſiſtance and ſtrength of certain horizontal pieces, when they come to execute their deſigns in large, by obſerving the ſame proportion as in the ſmall. Galileo's doctrine of reſiſtance, therefore, is no idle ſpeculation, but becomes applicable in architecture, and other arts.

The weight required to break a body, placed horizontally, being always leſs than that required to break it in a vertical ſituation; and this weight being to be greater or leſs, according to the ratio of the two arms of the lever, the whole theory is always reducible to this: *viz.* to find what part of the abſolute weight the relative weight is to be, ſuppoſing the figure of the body known; which indeed is neceſſary, becauſe it is the figure that determines the two centres of gravity, or the two arms of the lever. For if the body,

e. gr.

e. gr. were a cone, its centre of gravity would not be in the middle of its axis, as in the cylinder; and, if it were a ſemi-parabolical ſolid, neither would its centre of gravity be in the middle of its length or axis, nor the centre of gravity of its baſe in the middle of the axis of its baſe. But ſtill, whereſoever theſe centres fall in the ſeveral figures, the two arms of the lever are eſtimated accordingly.

It may be here obſerved, that if the baſe, by which the body is faſtened into the wall, be not circular, but, *e. gr.* parabolical, and the vertex of the parabola be at the top, the motion of the fracture will not be on an immoveable point, but on a whole immoveable line; which may be called the *axis of equilibrium;* and it is with regard to this that the diſtances of the centres of gravity are to be determined.

Now, a body horizontally ſuſpended, being ſuppoſed ſuch as that the ſmalleſt addition of weight would break it, there is an equilibrium between its poſitive and relative weight; and of conſequence thoſe two oppoſite powers are to each other reciprocally as the arms of the lever to which they are applied. On the other hand, the reſiſtance of a body is always equal to the greateſt weight which it will ſuſtain in a vertical ſituation, without breaking, *i. e.* is equal to its abſolute weight. Therefore, ſubſtituting the abſolute weight for the reſiſtance, it appears that the abſolute weight of a body, ſuſpended horizontally, is to its relative weight as the diſtance of its centre of gravity from the axis of equilibrium is to the diſtance of the centre of gravity of its baſe from the ſame axis.

The diſcovery of this important truth, at leaſt an equivalent to it, and to which this is reducible, we owe to Galileo. From this fundamental propoſition are eaſily deduced ſeveral conſequences; as, for inſtance, that, if the diſtance of the centre of gravity of the baſe from the axis of equilibrium be half the diſtance of the centre of gravity of the body, the relative weight will only be half the abſolute weight; and that a cylinder of copper, horizontally ſuſpended, whoſe length is double the diameter, will break, provided it weigh half what a cylinder of the ſame baſe, 4801 fathoms long, weighs.

On this theory of reſiſtance, which we owe to Galileo, M. Mariotte made a very ingenious remark, which gave birth to a new ſyſtem. Galileo ſuppoſes, that, where the body breaks, all the fibres break at once; ſo that the body always reſiſts with its whole abſolute force, or with the whole force that all its fibres have in the place where it is to be broke. But M. Mariotte, finding that all bodies, even glaſs itſelf, bend before they broke, ſhews that fibres are to be conſidered as ſo many little bent ſprings, which never exert their whole force till ſtretched to a certain point, and never break till entirely unbent. Hence, thoſe neareſt the axis of equilibrium, which is an immoveable line, are ſtretched leſs than thoſe farther off; and, of conſequence, employ a leſs part of their force.

This conſideration only takes place in the horizontal ſituation of the body: in the vertical, the fibres of the baſe all break at once; ſo that the abſolute weight of the body muſt exceed the united reſiſtance of all its fibres; a greater weight is, therefore, required here than in the horizontal ſituation; that is, a greater weight is required to overcome their united reſiſtance, than to overcome their ſeveral reſiſtances one after another. The difference between the two ſituations ariſes hence, that, in the horizontal, there is an immoveable point or line, as a centre of motion, which is not in the vertical.

Varignon has improved on the ſyſtem of M. Mariotte, and ſhewn, that, to Galileo's ſyſtem, it adds the conſideration of the centre of percuſſion. The compariſon of the centres of gravity with the centres of percuſſion afford a fine view, and ſet the whole doctrine in a moſt agreeable light.

In each ſyſtem, the baſe, by which the body breaks, moves on the axis of equilibrium, which is an immoveable line in the ſame baſe; but in the ſecond, the fibres of this baſe are continually ſtretching more and more, and that in the ſame ratio as they recede farther and farther from the axis of equilibrium; and, of conſequence, are ſtill exerting a greater and greater part of their whole force.

Theſe unequal extenſions, like all other forces, muſt have ſome common centre where they all meet, and with regard to which they make equal efforts on each ſide; and as they are preciſely in the ſame proportion as the velocities which the ſeveral points of a rod moved circularly would have to one another, the centre of extenſion of the baſe, by which the body breaks, or tends to break, muſt be the ſame with its centre of percuſſion. Galileo's hypotheſis, according to which the fibres are ſuppoſed to ſtretch equally, and break all at once, correſponds to the caſe of a rod moving parallel to itſelf, where the centre of extenſion or percuſſion does not appear, as being confounded with the centre of gravity.

The baſe of fraction being a ſurface, whoſe particular nature determines its centre of percuſſion, it is neceſſary that this ſhould be firſt known, to find on what point of the vertical axis of that baſe it is placed, and how far it is from the axis of equilibrium. Indeed, we know in the general, that it always acts with ſo much the more advantage as it is farther from it; becauſe it acts by a longer arm of a lever; and of conſequence it is the unequal reſiſtance of the fibres in M. Mariotte's hypotheſis, which produces the centre of percuſſion; but this unequal reſiſtance is greater or leſs, according as the centre of percuſſion is placed more or leſs high on the vertical axis of the baſe, in the different ſurfaces of the baſe of the fracture.

To expreſs this unequal reſiſtance, accompanied with all the variation it is capable of, regard muſt be had to the ratio between the diſtance of the centre of percuſſion from the axis of equilibrium, and the length of the vertical axis of the baſe. In which ratio, the firſt term, or the numerator, is always leſs than the ſecond, or the denominator; ſo that the ratio is always a fraction leſs than unity; and the unequal reſiſtance of the fibres in M. Mariotte's hypotheſis is ſo much the greater, or, which amounts to the ſame, approaches ſo much nearer to the equal reſiſtance in Galileo's hypotheſis, as the two terms of the ratio are nearer to an equality.

Hence it follows, that the reſiſtance of bodies in M. Mariotte's ſyſtem is to that in Galileo's, as the leaſt of the terms in the ratio is to the greateſt. Hence, alſo, the reſiſtance being leſs than what Galileo imagined, the relative weight muſt alſo be leſs; ſo that the proportion already mentioned between the abſolute and relative weight cannot ſubſiſt in the new ſyſtem, without an augmentation of the relative weight, or a diminution of the abſolute weight; which diminution is had by multiplying the weight by the ratio, which is always leſs than unity. This done, we find that the abſolute weight, multiplied by the ratio, is to the relative weight, as the diſtance of the centre of gravity of the body from the axis of equilibrium, is to the diſtance of the centre of gravity of the baſe of the fracture from the ſame axis: which is preciſely the ſame thing with the general formula given by M. Varignon for the ſyſtem of M. Mariotte. In effect, after conceiving the relative weight of a body, and its reſiſtance equal to its abſolute weight, as two contrary powers applied to the two arms of a lever, in the hypotheſis of Galileo, there needs nothing to convert it into

into that of M. Mariotte, but to imagine that the refiftance, or the abfolute weight, is become lefs, every thing elfe remaining the fame.

One of the moft curious, and perhaps the moft ufeful queftions in this refearch, is to find what figure a body muft have, that its refiftance may be equal in all its parts, whether it be loaded with an additional weight, or as only fuftaining its own weight.

To this end it is neceffary that fome part of it fhould be conceived to be cut off by a plane parallel to the fracture, fo that the momentum of the part retrenched, be to its refiftance in the fame ratio as the momentum of the whole is to its refiftance. Thefe four powers act by arms of levers peculiar to themfelves, and are proportional in the whole, and in each part, of a folid of equal refiftance. From this proportion Varignon deduces two folids, which fhall refift equally in all their parts, or be no more liable to break in one part than in another. Galileo had previoufly found one of thefe, which is that in which the fides are parabolical: the other, found by Varignon, is in the form of a trumpet, which is to be fixed into the wall by its greater end; fo that its magnitude or weight is always diminifhed in proportion as its length, or the arm of the lever by which it acts, is increafed. It is remarkable, that, however different the two fyftems may be, the folids of equal refiftance are the fame in both.

We cannot purfue the theory of refiftances to a greater length in the prefent article; but fhall confine ourfelves to exhibiting a general fynopfis of the moft important refults which have been drawn by different writers on this fubject, both practical and theoretical.

1. The refiftance of a beam, or bar, to a fracture, by a force acting laterally, is as the folid made by a fection of the beam in the place where the force is applied, into the diftance of its centre of gravity from the point or line where the breach will end.

2. In fquare beams, the lateral ftrengths are as the cubes of their breadths or depths.

3. In cylindric beams, the refiftances or ftrengths are as the cubes of the diameters.

4. In rectangular beams, the lateral ftrengths are conjointly as the breadths and fquares of the depths.

5. The lateral refiftances of any beams, whofe fections are fimilar figures and alike placed, are as the cubes of the like dimenfions of thofe figures.

6. The lateral ftrength of a beam, with its narrower face upwards, is to its ftrength with the broader face upwards, as the breadth of the broader face to the breadth of the narrower.

7. The lateral ftrengths of prifmatic beams of the fame materials, are as the areas of the fections, and the diftance of their centre of gravity, directly, and as their lengths and weights reciprocally.

8. When the beam is fixed at both ends, the fame property has place, except that, in this cafe, we muft confider the beam as only half the length of the former.

9. Cylinders and fquare prifms have their lateral ftrengths proportional to the cubes of their diameters, or depths, directly, and their lengths and weights inverfely.

10. Similar prifms and cylinders have their ftrength inverfely proportional to their linear dimenfions.

For other propofitions relative to the refiftance or ftrength of beams of various forms and in various pofitions, fee the article Strength *and Strefs of Materials*.

The following refults are wholly drawn from experiments on different fubftances, by Emerfon and other writers, by means of which the propofitions ftated in the preceding part of this article may be fubmitted to computation.

The relative Refiftances or Strengths of Wood and other Bodies.

	Proportional Refiftance.
Box, yew, plum-tree, oak	11
Elm, afh	$8\frac{1}{2}$
Walnut, thorn	$7\frac{1}{2}$
Red fir, hollin, elder, plane crab-tree, apple-tree	7
Beech, cherry-tree, hazel	$6\frac{2}{3}$
Alder, afp, birch, white fir, willow	6
Iron	107
Brafs	50
Bone	22
Lead	$6\frac{1}{2}$
Fine free-ftone	1

A cylindric rod of good clean fir, of an inch circumference, drawn in length, will bear at its extremity 400 lbs.; and a fpear of fir, of two inches diameter, will bear about feven ton weight. A rod of good iron, of an inch circumference, will bear nearly three ton weight. A good hempen rope, of an inch circumference, will bear 1000 lbs. at its extremity. Hence Emerfon concludes, that if a rod of fir, or a rope, or a rod of iron, of d inches diameter, were to lift a quarter of the extreme weight that they would fupport, then

The fir would bear $8\frac{1}{5}\ d^2$ hundred weight.
The rope - $22\ d^2$ ditto.
The iron - $6\frac{3}{4}\ d^2$ tons.

To thefe refults we may add, from the experiments and inveftigations of profeffor Robifon, that a prifm of white marble, an inch fquare and a foot long, bears about 500 lbs. And that, from the various authors he has collected, the cohefive force of a fquare inch of gold, when caft, is about 20,000 lbs.; of filver, 40,000 lbs.; caft iron from 40,000 to 60,000 lbs.; wrought iron from 60,000 to 90,000 lbs.; foft fteel, 12,000 lbs.; razor fteel, 15,000 lbs.; oak and beech, in the direction of their fibres, from 8000 to 17,000 lbs.; willow, 12,000 lbs.; cedar, 5000 lbs.; fir, 8000 lbs.; ivory, 16,000 lbs.; bone, 5000 lbs.; rope, 20,000 lbs. And a cylinder, an inch in diameter, loaded to one-fourth, will carry, if of iron, 135 cwt.; of rope, 22 cwt.; oak, 14 cwt.; and fir, 9 cwt.

The refiftance of fome metals is doubled, or tripled, by the operation of forging and wire-drawing; and the cohefive, as well as the repulfive, force of wood, is often increafed by moderate compreffion. Oak will *fufpend* much more than fir; but fir will *fupport* twice as much as oak; which difference is fuppofed to arife from the curvature of the fibres of oak; yet oak has been known to fupport, with fafety, more than two tons for every fquare inch. Stone will fupport from 250 to 850 thoufand pounds, on a foot fquare; brick, 300 lbs.; and fometimes they are practically made to fupport one-fixth as much. Stone is faid to be capable of bearing a much greater weight in that pofition in which it is found in the quarry, than in any other pofition. See Strength *of Materials*.

Resistance *of Fluids*, in *Hydroftatics*, is the force with which bodies, moving in fluid mediums, are impeded and retarded in their motion.

A body moving in a fluid is refifted from two caufes: the firft, the cohefion of the parts of the fluid. For a body, in its motion, feparating the parts of a liquid, muft overcome the force with which thofe parts cohere.

The fecond is the inertia, or inactivity of matter, by which

which a certain force is required to move the particles from their places, in order to let the body pafs.

The retardation from the firft caufe is always the fame in the fame fpace, the body remaining the fame, whatever be the velocity, that is, the refiftance is as the fpace run through in the fame time; in which ratio the velocity alfo increafes; and therefore the refiftance from the firft caufe is as the velocity itfelf.

The refiftance from the fecond caufe, when the fame body moves through different fluids with the fame velocity, follows the proportion of the matter to be removed in the fame time, which is as the denfity of the fluid.

When the fame body moves through the fame fluid with different velocities, this refiftance increafes in proportion to the number of particles ftruck in an equal time; which number is as the fpace run through in that time, that is, as the velocity. But it alfo increafes in proportion to the force with which the body ftrikes againft every part; which force is alfo as the velocity of the body; and therefore, if the velocity be triple, the refiftance is triple, from a triple number of parts to be removed. It is alfo triple from a ftroke three times ftronger againft every particle; therefore the whole refiftance is nine-fold, that is, as the fquare of the velocity. Hence, a body moved in a fluid is refifted partly in a ratio of the velocity, and partly in a duplicate ratio of it.

Hence, therefore, if d denotes the denfity of the fluid, v the velocity of the body, and a and b conftant co-efficients; then $a d v^2 + b v$ will be proportional to the whole refiftance to the fame body, moving with different velocities, in the fame direction through fluids of different denfities, but of the fame tenacity. But to take into confideration the different tenacities of fluids, let t denote the tenacity, or the cohefion of the parts of the fluid; then $a d v^2 + b t v$ will be as the faid whole refiftance.

The quantity of refiftance, however, arifing from the cohefion of the parts of the fluids, is very trifling with refpect to the other refiftance, except in very glutinous ones; and it alfo increafes in a much lower degree, being only as the velocity, while the other is as the fquare of the velocity. Hence then the term $b t v$ is very fmall, in refpect of the other term $a d v^2$, and, confequently, the refiftance is nearly as the latter term, or nearly as the fquare of the velocity: which formula has been employed by moft authors, and is, indeed, very nearly the truth in flow motions; but in very rapid ones it is far from correct, not fo much from the omiffion of the fmall term $b t v$, due to the cohefion; but from the want of the full counter preffure on the hinder part of the body, by which means a vacuum, either perfect or partial, is left behind the body in its motion; and alfo perhaps to fome compreffion or accumulation of the fluid againft the fore-part of the body. Therefore, in order to conceive the refiftance of fluids to a body moving in them, it is neceffary to diftinguifh between thofe fluids which, being compreffed by fome incumbent weight, perpetually clofe up the fpace behind the body in motion, without permitting, for an inftant, any vacuity to remain behind it; and thofe fluids which, not being fufficiently compreffed, the fpace left behind the moving body remains for fome time empty. Thefe differences, in the refifting fluids, will occafion very remarkable varieties in the laws of their refiftance, and are abfolutely neceffary to be confidered in the determination of the action of the air on fhot and fhells; for the air partakes of both thefe affections, according to the different velocities of the projected body.

In treating of thefe refiftances, the fluids may likewife be confidered as continued or difcontinued, that is, as having their particles contiguous, or as being feparated and unconnected, and alfo as either elaftic or non-elaftic.

If a fluid was fo conftituted, that all the particles compofing it were at fome diftance from each other, and there was no action between them, then the refiftance of a body moving in it would be eafily computed, from the quantity of motion communicated to thefe particles: for inftance, if a cylinder moved in fuch a fluid in the direction of its axis, it would communicate to the particles it met with a velocity equal to its own, and in its own direction, fuppofing that neither the cylinder, nor the parts of the fluid, were elaftic; whence, if the velocity and diameter of the cylinder be known, and alfo the denfity of the fluid, there would thence be determined the quantity of motion communicated to the fluid, which, action and re-action being equal, is the fame with the quantity loft by the cylinder, confequently the refiftance would be thereby afcertained.

In this kind of difcontinued fluid, the particles being detached from each other, every one of them can purfue its own motion in any direction, at leaft for fome time, independent of the neighbouring ones; wherefore, if inftead of a cylinder, moving in the direction of its axis, a body, with a furface oblique to its direction, be fuppofed to move in fuch a fluid, the motion which the parts of the fluid will hereby acquire, will not be in the direction of the refifted body, but perpendicular to its oblique furface; whence the refiftance to fuch a body will not be eftimated from the whole motion communicated to the particles of the fluid, but from that part of it only which is in the direction of the refifted body. In fluids then, where the parts are thus difcontinued from each other, the different obliquities of that furface, which goes foremoft, will occafion confiderable changes in the refiftance; although the fection of the folid, by a plane perpendicular to its direction, fhould in all cafes be the fame. And fir Ifaac Newton has particularly determined, that, in a fluid thus conftituted, the refiftance of a globe is but half the refiftance of a cylinder of the fame diameter, moving in the direction of its axis with the fame velocity.

But though the hypothefis of a fluid, thus conftituted, be of great ufe in explaining the nature of refiftances; yet, in reality, we know of no fuch fluid exifting in nature; all the fluids, with which we are converfant, are fo formed, that their particles either lie contiguous to each other, or at leaft act on each other in the fame manner as if they did; confequently, in thefe fluids, no one particle contiguous to the refifted body can be moved, without moving at the fame time a great number of others, fome of which will be diftant from it; and the motion thus communicated to a mafs of the fluid, will not be in any one determined direction, but will in each particle be different, according to the different manners in which it lies in contact with thofe from which it receives its impulfe; whence great numbers of the particles being diverted into oblique directions, the refiftance of the moving body, which will depend on the quantity of motion communicated to the fluid in its own direction, will neceffarily be different in quantity, from what it would be in the preceding fuppofition, and its eftimation becomes much more complicated and operofe.

If the fluid be compreffed by the incumbent weight of its upper parts, as all the fluids are with us, except at their very furface, and if the velocity of the moving body be much lefs than that with which the parts of the fluid would rufh into a void fpace, in confequence of their compreffion; it is evident, that in this cafe the fpace left by the moving body will be inftantaneoufly filled up by the fluid; and the

parts

parts of the fluid, againſt which the foremoſt part of the body preſſes in its motion, will, inſtead of being impelled forwards in the direction of the body, circulate in ſome meaſure towards the hinder part of it, thereby to reſtore the equilibrium, which the conſtant influx of the fluid behind the body would otherwiſe deſtroy; whence the progreſſive motion of the fluid, and conſequently the reſiſtance of the body, which depends on it, would be in this inſtance much leſs than in the hypotheſis, where each particle is ſuppoſed to acquire, from the ſtroke of the reſiſting body, a velocity equal to that with which the body moved, and in the ſame direction. Sir Iſaac Newton has determined, that the reſiſtance of a cylinder, moving in the direction of its axis, in ſuch a compreſſed fluid as we have here treated of, is but one-fourth part of the reſiſtance which the ſame cylinder would undergo, if it moved with the ſame velocity, in a fluid conſtituted in the manner deſcribed in the firſt hypotheſis, each fluid being ſuppoſed to be of the ſame denſity.

But again, it is not only in the quantity of their reſiſtance that theſe fluids differ, but likewiſe in the different manner in which they act on ſolids of different forms, moving in them. In the diſcontinued fluid, firſt deſcribed, the obliquity of the foremoſt ſurface of the moving body would diminiſh the reſiſtance; but in compreſſed fluids this holds not true, at leaſt not in any conſiderable degree; for the principal reſiſtance in compreſſed fluids ariſes from the greater or leſſer facility with which the fluid, impelled by the fore-part of the body, can circulate towards its hindermoſt part; and this being little, if at all, affected by the form of the moving body, whether it be cylindrical, conical, or ſpherical, it follows, that while the tranſverſe ſection of the body, and conſequently the quantity of impelled fluid is the ſame, the change of figure in the body will ſcarcely affect the quantity of its reſiſtance.

And this caſe, that is, the reſiſtance of a compreſſed fluid to a ſolid, moving in it with a velocity much leſs than what the parts of the fluid would acquire from their compreſſion; this caſe has been very fully conſidered by ſir Iſaac Newton, who has aſcertained the quantity of ſuch a reſiſtance according to the different magnitudes of the moving body, and the denſity of the fluid. But he very expreſsly informs us, that the rules he has laid down are not generally true, but upon a ſuppoſition that the compreſſion of the fluid be increaſed in the greater velocities of the moving body: however, ſome unſkilful writers, who have followed him, overlooking this caution, have applied his determination to bodies moving with all kinds of velocities, without attending to the different compreſſions of the fluids they are reſiſted by; and by this means they have accounted the reſiſtance of the air to muſket and cannon-ſhot, to be but one-third part of what it is found to be by experience.

It is indeed evident, that the reſiſting power of the medium muſt be increaſed, when the reſiſting body moves ſo faſt that the fluid cannot inſtantaneouſly preſs in behind it, and fill the deſerted ſpace; for when this happens the body will be deprived of the preſſure of the fluid behind it; which in ſome meaſure balanced its reſiſtance, and muſt ſupport on its fore-part the whole weight of a column of the fluid, independent of the motion it gives to the parts of the fluid; and beſides, the motion in the particles driven before the body, is, in this caſe, leſs affected by the compreſſion of the fluid, and conſequently they are leſs deflected from the direction in which they are impelled by the reſiſted ſurface; whence this ſpecies of reſiſtance approaches more and more to that deſcribed in the firſt hypotheſis, where each particle of the fluid being unconnected with the neighbouring ones, it purſues its own motion, in its own direction, without being interrupted or deflected by their contiguity; and therefore, as the reſiſtance of a diſcontinued fluid to a cylinder, moving in the direction of its axis, is four times greater than the reſiſtance of a fluid ſufficiently compreſſed of the ſame denſity; it follows, that the reſiſtance of a fluid, when a vacuity is left behind the moving body, may be nearly four times greater than that of the ſame fluid, when no ſuch vacuity is formed; for when a void ſpace is thus left, the reſiſtance approaches in its nature to that of a diſcontinued fluid.

This, then, may probably be the caſe in a cylinder moving in the ſame compreſſed fluid, according to the different degrees of its velocity; ſo that if it ſet out with a great velocity, and moves in the fluid till that velocity be much diminiſhed, the reſiſting power of the medium may be nearly four times greater in the beginning of its motion than in the end.

In a globe the difference will not be ſo great, becauſe, on account of its oblique ſurface, its reſiſtance in a diſcontinued medium is but about twice as much as in one properly compreſſed; for its oblique ſurface diminiſhes its reſiſtance in one caſe, and not in the other: however, as the compreſſion of the medium, even when a vacuity is left behind the moving body, may yet confine the oblique motion of the parts of the fluid, which are driven before the body, and as in an elaſtic fluid, as the air is, there will be ſome degree of condenſation in thoſe parts; it is highly probable, that the reſiſtance of a globe moving in a compreſſed fluid may greatly exceed the proportion of the reſiſtance to ſlow motions.

And as this increaſe of the reſiſting power of the medium will take place, when the velocity of the moving body is ſo great that a perfect vacuum is left behind it, ſo ſome degree of augmentation will be ſenſible in velocities much ſhort of this; for even when, by the compreſſion of the fluid, the ſpace left behind the body is inſtantaneouſly filled up; yet, if the velocity with which the parts of the fluid ruſh in behind, is not much greater than that with which the body moves, the ſame reaſons we have urged above, in the caſe of an abſolute vacuity, will hold in a leſs degree in this inſtance; and therefore we are not to ſuppoſe, that, in the increaſed reſiſtance which we have hitherto treated of, it immediately vaniſhes, when the compreſſion of the fluid is juſt ſufficient to prevent a vacuum behind the reſiſted body; but we muſt conſider it as diminiſhing only, according as the velocity with which the parts of the fluid follow the body, exceeds that with which the body moves.

Hence, then, we may conclude, that if a globe ſets out in a reſiſting medium, with a velocity much exceeding that with which the particles of the medium would ruſh into a void ſpace, in conſequence of their compreſſion, ſo that a vacuum is neceſſarily left behind the globe in its motion: the reſiſtance of this medium to the globe will be near three times greater, in proportion to its velocity, than what we are ſure, from ſir Iſaac Newton, would take place in a ſlower motion. We may alſo farther conclude, that the reſiſting power of the medium will gradually diminiſh as the velocity of the globe decreaſes, till at laſt, when it moves with a velocity which bears but a ſmall proportion to that with which the particles of the medium follow it, the reſiſtance becomes the ſame with what is aſſigned by ſir Iſaac Newton in the caſe of a compreſſed fluid.

And from this determination we ſee how falſe that poſition is, which aſſerts the reſiſtance of any medium to be in the duplicate proportion of the velocity of the reſiſted body;

body; for it is evident by what we have ſaid, that this can only be conſidered as nearly true in ſmall variations of velocity, and can never be applied in the comparing together of the reſiſtances to all velocities whatever, without the moſt enormous errors. See New Principles of Gunnery, by Mr. Robins, chap. 2. prop. 1. See RESISTANCE *of the Air*. See alſo PROJECTILE and GUNNERY.

Reſiſtance and retardation are uſed indifferently for each other, as being both in the ſame proportion, and the ſame reſiſtance always generating the ſame retardation. But, with regard to different bodies, the ſame reſiſtance frequently generates different retardations; the reſiſtance being as the quantity of motion, and the retardation as that of the celerity. For the difference and meaſure of the two, ſee RETARDATION.

The retardations from this reſiſtance may be compared together, by comparing the reſiſtance with the gravity or quantity of matter. Thus, let $v =$ the velocity; $a =$ the area of the face, or end of a cylinder; $n =$ the ſpecific gravity of the fluid; $g = 32\frac{1}{6}$ feet, the force of gravity; then the altitude due to the velocity v being $\frac{v^2}{2g}$, the whole reſiſtance, or motive force m, will be expreſſed by the following formulæ;

$$m = an \times \frac{v^2}{2g} = \frac{anv^2}{2g}; \text{ or } = \frac{anv^2s^3}{2g}:$$

the latter having place when the motion is not in a direction perpendicular to the plane or end, but is inclined to it at a given angle, whoſe ſine is s. For it is a known property, that, in this caſe, the reſiſtance varies as the cube of the ſine of the angle of inclination. If now w be made to denote the weight of the body, and f the retarding force; then, on the ſame principles, we derive

$$f = \frac{m}{w} = \frac{anv^2s^3}{2gw}.$$

If the body be a cylinder, moving in the direction of its axis, and the diameter of the baſe equal d, or radius r, and $\pi = 3.14159$, &c. then

$$f = \frac{m}{w} = \frac{\pi n d^2 v^2}{8gw} = \frac{\pi n r^2 v^2}{2gw}.$$

But when the cylinder moves in a direction perpendicular to its axis, then writing b for the height or length of the cylinder, we have

$$f = \frac{m}{w} = \frac{nv^2bd}{3gw} = \frac{nv^2br}{\frac{3}{2}gw}.$$

And when it moves obliquely to its axis, then writing s for the ſine of the angle of inclination, we have

$$f = \frac{nv^2rbs^3}{2g}\left\{1 - \frac{3s^2 - 1}{6} + \frac{3(s^2-1)^2}{40} + \frac{(s^2+5)(s^2-1)^3}{112} + \&c.\right\} + \frac{\pi n v^2 r^2}{2g}.(-s^2)^{\frac{1}{2}}$$

See Moore's Theory of Military Rockets.

If the body be a cone, then the ſame notation remaining, only writing s for the ſine of the angle of inclination of the ſide of the cone; then

$$f = \frac{m}{w} = \frac{\pi n d^2 v^2 s^2}{8gw} = \frac{\pi n r^2 v^2 s^2}{2gw}.$$

For, in this caſe, the inclination has no effect in reducing the ſection oppoſed to the reſiſtance of the fluid, this being the ſame as in the cylinder, and therefore will vary as s^2.

The ſame notation ſtill remaining, it is found, from a fluxional inveſtigation (ſee Gregory's Mechanics, vol. i.) that the reſiſtance of the body, when terminated with a hemiſpherical ſurface, is

$$f = \frac{m}{w} = \frac{\pi n d^2 v^2}{16gw} = \frac{\pi n r^2 v^2}{4gw}.$$

that is, half what it is when the end is a plane ſurface.

Hence the reſiſtance of a ſphere, when impelled through any fluid, is equal to half the direct reſiſtance to a great circle of it, or to a cylinder of the ſame diameter. Since $\frac{1}{6}\pi d^3$ is the magnitude of the globe, if N denotes its denſity, or ſpecific gravity, its weight $w = \frac{1}{6}\pi N d^3$; and, therefore, the retardive force becomes

$$f = \frac{m}{w} = \frac{\pi n v^2 d^2}{16gw} \times \frac{6}{\pi N d^3} = \frac{3nv^2}{8gNd} = \frac{v^2}{2gs},$$

where s is the ſpace deſcribed; for $2fgs = v^2$, by the law of accelerated or retarded motions. From which it appears, that the reſiſtance varies as the ſquare of the velocity directly, and as the diameter inverſely, all things elſe being the ſame; and hence the reaſon, why a large ball overcomes reſiſtance better than a ſmaller one.

James Bernouilli demonſtrates the following theorems, Acta Erud. Lipſ. for June 1693, p. 252, &c.

1. If an iſoſceles triangle be moved in a fluid according to the direction of a line perpendicular to its baſe; firſt, with the vertex foremoſt, and then with its baſe; the reſiſtances will be in the duplicate ratio of the baſe, and of the ſum of the legs.

2. The reſiſtance of a ſquare, moved according to the direction of its ſide, is to the reſiſtance of the ſame ſquare, moved with the ſame celerity in the direction of its diagonal, as the diagonal is to the ſide.

3. The reſiſtance of a circular ſegment, leſs than a ſemicircle, carried in a direction perpendicular to its baſis, when it goes with the baſe foremoſt, and when with its vertex foremoſt (the ſame direction and celerity continuing), is as the ſquare of the ſame diameter to the ſame, leſs one-third of the ſquare of the baſe of the ſegment. Hence, the reſiſtances of a ſemicircle, when its baſe and when its vertex go foremoſt, are to one another in a ſeſquialterate ratio.

4. A parabola moving in the direction of its axis, firſt with its baſis, and then its vertex foremoſt, has its reſiſtances as the tangent to an arc of a circle, whoſe diameter is equal to the parameter, and the tangent equal to half the baſis of the parabola.

5. The reſiſtances of an hyperbola and ellipſis, when the vertex and baſe go foremoſt, may be thus computed. Say, as the ſum (or difference) of the tranſverſe axis and latus rectum is to the tranſverſe axis, ſo is the ſquare of the latus rectum to the ſquare of the diameter of a certain circle; in which circle apply a tangent, equal to half the baſis of the hyperbola or ellipſe. Then ſay again, as the ſum (or difference) of the axis and parameter is to the parameter, ſo is the aforeſaid tangent to another right line. And farther, as the ſum (or difference) of the axis and parameter is to the axis, ſo is the circular arc correſponding to the aforeſaid tangent to another arc. This done, the reſiſtances will be as the tangent to the ſum (or difference) of the right line thus found, and the arc laſt mentioned.

6. In the general, the reſiſtances of any figure whatever, going now with its baſe foremoſt, and then with its vertex, are as the figures of the baſe to the ſum of all the cubes of the elements of the baſe, divided by the ſquares of the elements of the curve line.

All which rules may be of ufe in the conftruction of fhips, and in perfecting the art of navigation univerfally; as alfo for determining the figures of the balls of pendulums for clocks, &c.

RESISTANCE *of Fluid Mediums to the Motion of Falling Bodies.*—A body freely defcending in a fluid is accelerated by the refpective gravity of the body, which continually acts upon it, yet not equably, as in a vacuum: the refiftance of the fluid occafions a retardation, that is, a diminution of acceleration, which diminution increafes with the velocity of the body. Now there is a certain velocity, which is the greateft a body can acquire by falling; for if its velocity be fuch, that the refiftance arifing from it becomes equal to the refpective weight of the body, its motion can be no longer accelerated; for the motion here continually generated by the refpective gravity, will be deftroyed by the refiftance, and the body forced to go on equably. A body continually comes nearer and nearer to this greateft celerity, but can never attain to it.

When the denfities of a fluid body are given, the refpective weight of the body may be known; and by knowing the diameter of the body, it may be found from what height a body falling in vacuo can acquire fuch a velocity as that the refiftance in a fluid fhall be equal to that refpective weight, which will be that greateft velocity above-mentioned. If the body be a fphere, it is known, that a fphere is equal to a cylinder of the fame diameter, whofe height is two-third parts of that diameter; which height is to be increafed in the ratio in which the refpective weight of the body exceeds the weight of the fluid, in order to have the height of a cylinder of the fluid, whofe weight is equal to the refpective weight of the body; but if you double this height, you will have a height from which a body falling in vacuo acquires fuch a velocity as generates a refiftance equal to this refpective weight, and which therefore is the greateft velocity which a body can acquire, by falling in a fluid, from an infinite height. Lead is eleven times heavier than water; wherefore its refpective weight is to the weight of water, as ten to one; therefore a leaden ball, as appears from what has been faid, cannot acquire a greater velocity, in falling in water, than it would acquire in falling in vacuo, from a height of $13\frac{1}{3}$ of its diameters.

A body lighter than a fluid, and afcending in it by the action of the fluid, is moved exactly by the fame laws as a heavier body falling in the fluid. Wherever the body is placed, it is fuftained by the fluid, and carried up with a force equal to the difference between the weight of a quantity of the fluid of the fame bulk as the body, and the body itfelf; by which not only the action of gravity of the body is deftroyed; but the body is alfo carried upwards by a motion equably accelerated, in the fame manner as a body heavier than a fluid defcends by its refpective gravity: but the equability of the acceleration is deftroyed in the fame manner by the refiftance, in the afcent of a body lighter than the fluid, as it is deftroyed in the defcent of a body heavier.

When a body fpecifically heavier than a fluid is thrown in it, it is retarded upon a double account; on account of the gravity of the body, and on account of the refiftance of the fluid; confequently, a body rifes to a lefs height than it would rife to in vacuo with the fame celerity. But the defects of the height in a fluid from the height to which a body would rife in vacuo with the fame celerity, have a greater proportion to each other than the heights themfelves; and in lefs heights the defects are nearly as the fquares of the heights in vacuo.

In order to fubmit the above principles to accurate computation, we muft refer back to our preceding determination of the retardative force of a fluid to a body moving it, which we found to be

$$f = \frac{m}{w} = \frac{\pi n v^2 d^2}{16 g w} \times \frac{6}{\pi N d^3} = \frac{3 n v^2}{8 g N d} = \frac{v^2}{2 g s};$$

from the two latter terms of which we have $s = \frac{N}{n} \times \frac{4}{3} d$;

which is the fpace that would be defcribed by the globe, while its whole motion is generated or deftroyed by a conftant force, which is equal to the forces of refiftance, if no other force acted on the globe to continue its motion. And if the denfity of the fluid were equal to that of the globe, the refifting force is fuch as, acting conftantly on the globe without any other force, would generate or deftroy its motion in defcribing the fpace $\frac{4}{3}d$, or $\frac{4}{3}$ of its diameter, by that accelerating or retarding force.

Hence the greateft velocity that a ball will acquire by defcending in a fluid by means of its relative weight in that fluid, will be found by making the refifting force equal to that weight. For, after the velocity has arrived at fuch a degree, that the refifting force is equal to the weight that urges it, it will increafe no longer, and the globe will then continue to defcend with an uniform velocity.

Now N and n being the feparate fpecific gravities of the globe and fluid, $N - n$ will be the relative gravity of the globe in the fluid; and, therefore, $w = \frac{1}{6} \pi d^3 (N - n)$ is the weight by which it is urged, $m = \frac{\pi n v^2 d^2}{16 g}$ is the refiftance; confequently $\frac{\pi n v^2 d^2}{16 g} = \frac{1}{6} \pi d^3 (N - n)$ when the velocity becomes uniform; whence we obtain

$$v = \sqrt{\left(2 g \times \frac{4}{3} d \times \frac{N - n}{n}\right)}$$

for the uniform or greateft velocity of the globe.

Thus, for example, if a leaden ball one inch in diameter defcend in water, and in air of the fame denfity as at the earth's furface; the three fpecific gravities being, lead $= 11\frac{1}{3}$, water $= 1$, and air $= \frac{3}{2500}$; then

$$v = \sqrt{(2 \times 32\tfrac{1}{6} \times \frac{4}{36} \times 10\tfrac{1}{3})} = 8.5944 \text{ feet}$$

per fecond for the greateft velocity in water; and

$$v = \sqrt{\left(4 \times \frac{193}{12} \times \frac{4}{36} \times \frac{34}{3} \times \frac{2500}{3}\right)} = 259.82 \text{ feet}$$

per fecond for the greateft velocity in air.

But as this velocity, all other things being the fame, varies as $\sqrt{d}$; it follows that a ball of $\frac{1}{100}$th of an inch diameter would only acquire velocities $\frac{1}{10}$th of thofe given above. Hence it appears, how foon fmall bodies come to their greateft or uniform velocity in defcending in fluids, and how very fmall that velocity is; which explains the reafon of the flow precipitation of mud and fmall particles in water, as alfo why, in precipitations, the larger and grofs particles defcend fooneft and loweft.

It appears alfo, from the preceding formulæ, that where $N = n$, or the denfity of the body is equal to that of the fluid; then $N - n = 0$, and confequently the velocity and fpace are in this cafe both equal to zero, as they ought to be.

Again, when the body is lighter than the fluid, then $N - n$ becomes negative, and the motion and force both tend the contrary way; that is, the ball will afcend by the same laws by which, in the preceding case, the heavier body descended, as stated in the preceding part of this article.

Resistance *of the Air*, in *Pneumatics*, is the force with which the motion of bodies, particularly of projectiles, is retarded by the opposition of the air or atmosphere. See Gunnery.

The air being a fluid, the general laws of the resistance of fluids obtain in it, except that the different degrees of density, in the different stages or regions of the atmosphere, occasion some irregularity.

As to the resistance of the air, it has been thus determined from experiments. Mr. Robins, in his New Principles of Gunnery, chap. 2. prop. 2, &c. having taken a musket barrel, and charging it successively with a leaden ball of three-quarters of an inch diameter, and about half its weight of powder, and taking such precaution in weighing of the powder, and placing it, as to be sure, by many previous trials, that the velocity of the ball could not differ by 20 feet in 1″ from its medium quantity, fired it against a pendulum, called the ballistic pendulum, (described under Gunnery), placed at 25 feet, at 75 feet, and at 125 feet distance from the mouth of the piece respectively. In the first case, it impinged against the pendulum with a velocity of 1670 feet in 1″; in the second case, with a velocity of 1550 feet in 1″; and in the third case, with a velocity of 1425 feet in 1″; so that in passing through 50 feet of air, the bullet lost a velocity of about 120 or 125 feet in 1″; and the time of its passing through that space being about $\frac{1}{33}$d or $\frac{1}{30}$th of 1″, the medium quantity of resistance must, in these instances, have been about 120 times the weight of the ball; which, as the ball was nearly $\frac{1}{12}$th of a pound, amounts to about 10lbs. avoirdupois.

Now, if a computation be made, according to the method laid down for compressed fluids, in the 38th propos. of lib. ii. of sir Isaac Newton's Principia, supposing the weight of water to be to the weight of air as 850 to 1, it will be found that the resistance of a globe of three-quarters of an inch diameter, moving with a velocity of about 1600 feet in 1″, will not, on those principles, amount to any more than a force of $4\frac{1}{6}$lbs. avoirdupois; whence we may conclude, the rules in that proposition for slow motions being very accurate, that the resisting power of the air in slow motions is less than in swift motions, in the ratio of $4\frac{1}{6}$ to 10, a proportion between that of 1 to 2, and 1 to 3.

Again, charging the same piece with equal quantities of powder, and balls of the same weight, and firing three times at the pendulum, placed at 25 feet distance from the mouth of the piece, the medium of the velocities with which the ball impinged was nearly that of 1690 feet in 1″. Then removing the piece 175 feet from the pendulum, the velocity of the ball, at a medium of five shots, was that of 1300 feet in 1″. Whence the ball, in passing through 150 feet of air, lost a velocity of about 390 feet in 1″; and the resistance, computed from these numbers, gives something more than in the preceding instance, amounting to between 11 and 12 pounds avoirdupois: whence, according to these experiments, the resisting power of the air to swift motions is greater than in slow ones, in a ratio which approaches nearer to the ratio of 3 to 1, than in the preceding experiments. Next, to examine this resistance in smaller velocities, the pendulum being placed at 25 feet distance, was fired at five times, with an equal charge each time, and the mean velocity with which the ball impinged, was that of 1180 feet in 1″. Then removing the pendulum to the distance of 250 feet, the medium velocity of five shot, at this distance, was that of 950 feet in 1″; whence the ball, in passing through 225 feet of air, lost a velocity of 230 feet in 1″, and as it passed through that interval in about $\frac{3}{13}$ths of 1″, the resistance to the middle velocity will come out to be near $33\frac{1}{2}$ times the gravity of the ball, or 2lb. 10oz. avoirdupois. Now the resistance to the same velocity, according to the laws observed in slower motions, amounts to $\frac{7}{11}$ths of the same quantity; whence, in a velocity of 1065 feet in 1″ (the medium of 1180 and 950), the resisting power of the air is augmented in no greater proportion than that of 7 to 11; whereas, in greater degrees of velocity, as before, it amounted very nearly to the ratio of 1 to 3.

By other experiments, it appears, that the resistance of the air is very sensibly increased, even in so small a velocity as that of 400 feet in 1″.

That this resisting power of the air to swift motions is very sensibly increased beyond what sir Isaac's theory for slow motions makes it, seems hence to be evident. It being, as has been said, in musket, or cannon shot, with their full charge of powder, nearly three times the quantity assigned by that theory.

However, this increased power of resistance diminishes as the velocity of the resisted body diminishes, till at length, when the motion is sufficiently abated, the actual resistance coincides with that supposed in the theory.

The resistance of a bullet of three-quarters of an inch diameter, moving in air with the velocity of 1670 feet in 1″, amounting, as we said, to 10lbs., the resistance of a cannon ball of 24lbs., fired with 16lbs., or its full charge of powder, and thereby moving with a velocity of 1650 feet in 1″, (which scarcely differs from the other), may hence be determined. For the velocity of the cannon ball being nearly the same as the musket bullet, and its surface above 54 times greater, it follows, that the resistance on the cannon ball will amount to more than 540lbs. which is nearly 23 times its own weight.

Euler has shewn, that the common doctrine of resistance answers very well when the motion is not very swift, but in very swift motions it gives the resistance less than it ought to be, on two accounts. 1. Because in very quick motions the air does not fill up the space behind the body fast enough to press on the hinder parts, that the resistance on the fore part is increased. 2. The density of the air before the ball, being increased by the quick motion, will press more strongly on the fore part, and, being heavier than in its natural state, will retard its motion.

He has also shewn, that Mr. Robins has restrained his rule to velocities not exceeding 1670 feet in 1″; whereas, had he extended it to greater velocities, the result must have been erroneous: as he apprehends that it is not perfectly exact, when the motion is not extremely swift. He has investigated a formula for determining the degree of this resistance, and deduced conclusions differing from those of Mr. Robins. See Principles of Gunnery investigated, &c. 1777, p. 224, &c.

Mr. Robins having proved that, in very great changes of velocity, the resistance does not accurately follow the duplicate proportion of the velocity, lays down two positions, which may be of considerable service in the practice of artillery, till a more complete and accurate theory of resistance, and the changes of its augmentation, may be obtained. The first of these is, that till the velocity of the projectile surpasses that of 1100 feet in a second, the resistance may be esteemed to be in the duplicate proportion of the velocity: and the second is, that if the velocity be greater than that of 1100 or 1200 feet in a second, the absolute quantity of the resistance will be nearly three times as great as it should be by a comparison with the smaller velocities. Upon these principles, he proceeds in approximating the actual ranges of pieces with small angles of elevation, *viz.* such as do not exceed 8° or 10°, which he sets down in a table, compared with their corresponding potential ranges. See his Mathematical Tracts, vol. i. p. 179, &c.

Since

All which rules may be of ufe in the conftruction of fhips, and in perfecting the art of navigation univerfally; as alfo for determining the figures of the balls of pendulums for clocks, &c.

Resistance *of Fluid Mediums to the Motion of Falling Bodies.*—A body freely defcending in a fluid is accelerated by the refpective gravity of the body, which continually acts upon it, yet not equably, as in a vacuum: the refiftance of the fluid occafions a retardation, that is, a diminution of acceleration, which diminution increafes with the velocity of the body. Now there is a certain velocity, which is the greateft a body can acquire by falling; for if its velocity be fuch, that the refiftance arifing from it becomes equal to the refpective weight of the body, its motion can be no longer accelerated; for the motion here continually generated by the refpective gravity, will be deftroyed by the refiftance, and the body forced to go on equably. A body continually comes nearer and nearer to this greateft celerity, but can never attain to it.

When the denfities of a fluid body are given, the refpective weight of the body may be known; and by knowing the diameter of the body, it may be found from what height a body falling in vacuo can acquire fuch a velocity as that the refiftance in a fluid fhall be equal to that refpective weight, which will be that greateft velocity above-mentioned. If the body be a fphere, it is known, that a fphere is equal to a cylinder of the fame diameter, whofe height is two-third parts of that diameter; which height is to be increafed in the ratio in which the refpective weight of the body exceeds the weight of the fluid, in order to have the height of a cylinder of the fluid, whofe weight is equal to the refpective weight of the body; but if you double this height, you will have a height from which a body falling in vacuo acquires fuch a velocity as generates a refiftance equal to this refpective weight, and which therefore is the greateft velocity which a body can acquire, by falling in a fluid, from an infinite height. Lead is eleven times heavier than water; wherefore its refpective weight is to the weight of water, as ten to one; therefore a leaden ball, as appears from what has been faid, cannot acquire a greater velocity, in falling in water, than it would acquire in falling in vacuo, from a height of $13\frac{1}{3}$ of its diameters.

A body lighter than a fluid, and afcending in it by the action of the fluid, is moved exactly by the fame laws as a heavier body falling in the fluid. Wherever the body is placed, it is fuftained by the fluid, and carried up with a force equal to the difference between the weight of a quantity of the fluid of the fame bulk as the body, and the body itfelf; by which not only the action of gravity of the body is deftroyed; but the body is alfo carried upwards by a motion equably accelerated, in the fame manner as a body heavier than a fluid defcends by its refpective gravity: but the equability of the acceleration is deftroyed in the fame manner by the refiftance, in the afcent of a body lighter than the fluid, as it is deftroyed in the defcent of a body heavier.

When a body fpecifically heavier than a fluid is thrown in it, it is retarded upon a double account; on account of the gravity of the body, and on account of the refiftance of the fluid; confequently, a body rifes to a lefs height than it would rife to in vacuo with the fame celerity. But the defects of the height in a fluid from the height to which a body would rife in vacuo with the fame celerity, have a greater proportion to each other than the heights themfelves; and in lefs heights the defects are nearly as the fquares of the heights in vacuo.

In order to fubmit the above principles to accurate computation, we muft refer back to our preceding determination of the retardative force of a fluid to a body moving it, which we found to be

$$f = \frac{m}{w} = \frac{\pi n v^2 d^2}{16 g w} \times \frac{6}{\pi N d^3} = \frac{3 n v^2}{8 g N d} = \frac{v^2}{2 g s};$$

from the two latter terms of which we have $s = \frac{N}{n} \times \frac{4}{3} d$;

which is the fpace that would be defcribed by the globe, while its whole motion is generated or deftroyed by a conftant force, which is equal to the forces of refiftance, if no other force acted on the globe to continue its motion. And if the denfity of the fluid were equal to that of the globe, the refifting force is fuch as, acting conftantly on the globe without any other force, would generate or deftroy its motion in defcribing the fpace $\frac{4}{3}d$, or $\frac{4}{3}$ of its diameter, by that accelerating or retarding force.

Hence the greateft velocity that a ball will acquire by defcending in a fluid by means of its relative weight in that fluid, will be found by making the refifting force equal to that weight. For, after the velocity has arrived at fuch a degree, that the refifting force is equal to the weight that urges it, it will increafe no longer, and the globe will then continue to defcend with an uniform velocity.

Now N and n being the feparate fpecific gravities of the globe and fluid, $N - n$ will be the relative gravity of the globe in the fluid; and, therefore, $w = \frac{1}{6} \pi d^3 (N - n)$ is the weight by which it is urged, $m = \frac{\pi n v^2 d^2}{16 g}$ is the refiftance; confequently $\frac{\pi n v^2 d^2}{16 g} = \frac{1}{6} \pi d^3 (N - n)$ when the velocity becomes uniform; whence we obtain

$$v = \sqrt{\left(2 g \times \frac{4}{3} d \times \frac{N - n}{n}\right)}$$

for the uniform or greateft velocity of the globe.

Thus, for example, if a leaden ball one inch in diameter defcend in water, and in air of the fame denfity as at the earth's furface; the three fpecific gravities being, lead $= 11\frac{1}{3}$, water $= 1$, and air $= \frac{3}{2500}$; then

$$v = \sqrt{(2 \times 32\tfrac{1}{6} \times \frac{4}{36} \times 10\tfrac{1}{3})} = 8.5944 \text{ feet}$$

per fecond for the greateft velocity in water; and

$$v = \sqrt{\left(4 \times \frac{193}{12} \times \frac{4}{36} \times \frac{34}{3} \times \frac{2500}{3}\right)} = 259.82 \text{ feet}$$

per fecond for the greateft velocity in air.

But as this velocity, all other things being the fame, varies as $\sqrt{d}$; it follows that a ball of $\frac{1}{100}$th of an inch diameter would only acquire velocities $\frac{1}{10}$th of thofe given above. Hence it appears, how foon fmall bodies come to their greateft or uniform velocity in defcending in fluids, and how very fmall that velocity is; which explains the reafon of the flow precipitation of mud and fmall particles in water, as alfo why, in precipitations, the larger and grofs particles defcend fooneft and loweft.

It appears alfo, from the preceding formulæ, that where $N = n$, or the denfity of the body is equal to that of the fluid; then $N - n = 0$, and confequently the velocity and fpace are in this cafe both equal to zero, as they ought to be.

Again, when the body is lighter than the fluid, then $N - n$ becomes negative, and the motion and force both tend the contrary way; that is, the ball will afcend by the ſame laws by which, in the preceding caſe, the heavier body deſcended, as ſtated in the preceding part of this article.

Resistance *of the Air*, in *Pneumatics*, is the force with which the motion of bodies, particularly of projectiles, is retarded by the oppoſition of the air or atmoſphere. See Gunnery.

The air being a fluid, the general laws of the reſiſtance of fluids obtain in it, except that the different degrees of denſity, in the different ſtages or regions of the atmoſphere, occaſion ſome irregularity.

As to the reſiſtance of the air, it has been thus determined from experiments. Mr. Robins, in his New Principles of Gunnery, chap. 2. prop. 2, &c. having taken a muſket barrel, and charging it ſucceſſively with a leaden ball of three-quarters of an inch diameter, and about half its weight of powder, and taking ſuch precaution in weighing of the powder, and placing it, as to be ſure, by many previous trials, that the velocity of the ball could not differ by 20 feet in 1″ from its medium quantity, fired it againſt a pendulum, called the balliſtic pendulum, (deſcribed under Gunnery), placed at 25 feet, at 75 feet, and at 125 feet diſtance from the mouth of the piece reſpectively. In the firſt caſe, it impinged againſt the pendulum with a velocity of 1670 feet in 1″; in the ſecond caſe, with a velocity of 1550 feet in 1″; and in the third caſe, with a velocity of 1425 feet in 1″; ſo that in paſſing through 50 feet of air, the bullet loſt a velocity of about 120 or 125 feet in 1″; and the time of its paſſing through that ſpace being about $\frac{1}{32}$d or $\frac{1}{30}$th of 1″, the medium quantity of reſiſtance muſt, in theſe inſtances, have been about 120 times the weight of the ball; which, as the ball was nearly $\frac{1}{17}$th of a pound, amounts to about 10lbs. avoirdupois.

Now, if a computation be made, according to the method laid down for compreſſed fluids, in the 38th propoſ. of lib. ii. of ſir Iſaac Newton's Principia, ſuppoſing the weight of water to be to the weight of air as 850 to 1, it will be found that the reſiſtance of a globe of three-quarters of an inch diameter, moving with a velocity of about 1600 feet in 1″, will not, on thoſe principles, amount to any more than a force of $4\frac{1}{6}$lbs. avoirdupois; whence we may conclude, the rules in that propoſition for ſlow motions being very accurate, that the reſiſting power of the air in ſlow motions is leſs than in ſwift motions, in the ratio of $4\frac{1}{6}$ to 10, a proportion between that of 1 to 2, and 1 to 3.

Again, charging the ſame piece with equal quantities of powder, and balls of the ſame weight, and firing three times at the pendulum, placed at 25 feet diſtance from the mouth of the piece, the medium of the velocities with which the ball impinged was nearly that of 1690 feet in 1″. Then removing the piece 175 feet from the pendulum, the velocity of the ball, at a medium of five ſhots, was that of 1300 feet in 1″. Whence the ball, in paſſing through 150 feet of air, loſt a velocity of about 390 feet in 1″; and the reſiſtance, computed from theſe numbers, gives ſomething more than in the preceding inſtance, amounting to between 11 and 12 pounds avoirdupois: whence, according to theſe experiments, the reſiſting power of the air to ſwift motions is greater than in ſlow ones, in a ratio which approaches nearer to the ratio of 3 to 1, than in the preceding experiments. Next, to examine this reſiſtance in ſmaller velocities, the pendulum being placed at 25 feet diſtance, was fired at five times, with an equal charge each time, and the mean velocity with which the ball impinged, was that of 1180 feet in 1″. Then removing the pendulum to the diſtance of 250 feet, the medium velocity of five ſhot, at this diſtance, was that of 950 feet in 1″; whence the ball, in paſſing through 225 feet of air, loſt a velocity of 230 feet in 1″, and as it paſſed through that interval in about $\frac{3}{14}$ths of 1″, the reſiſtance to the middle velocity will come out to be near $33\frac{1}{2}$ times the gravity of the ball, or 2lb. 10oz. avoirdupois. Now the reſiſtance to the ſame velocity, according to the laws obſerved in ſlower motions, amounts to $\frac{7}{11}$ths of the ſame quantity; whence, in a velocity of 1065 feet in 1″ (the medium of 1180 and 950), the reſiſting power of the air is augmented in no greater proportion than that of 7 to 11; whereas, in greater degrees of velocity, as before, it amounted very nearly to the ratio of 1 to 3.

By other experiments, it appears, that the reſiſtance of the air is very ſenſibly increaſed, even in ſo ſmall a velocity as that of 400 feet in 1″.

That this reſiſting power of the air to ſwift motions is very ſenſibly increaſed beyond what ſir Iſaac's theory for ſlow motions makes it, ſeems hence to be evident. It being, as has been ſaid, in muſket, or cannon ſhot, with their full charge of powder, nearly three times the quantity aſſigned by that theory.

However, this increaſed power of reſiſtance diminiſhes as the velocity of the reſiſted body diminiſhes, till at length, when the motion is ſufficiently abated, the actual reſiſtance coincides with that ſuppoſed in the theory.

The reſiſtance of a bullet of three-quarters of an inch diameter, moving in air with the velocity of 1670 feet in 1″, amounting, as we ſaid, to 10lbs., the reſiſtance of a cannon ball of 24lbs., fired with 16lbs., or its full charge of powder, and thereby moving with a velocity of 1650 feet in 1″, (which ſcarcely differs from the other), may hence be determined. For the velocity of the cannon ball being nearly the ſame as the muſket bullet, and its ſurface above 54 times greater, it follows, that the reſiſtance on the cannon ball will amount to more than 540lbs. which is nearly 23 times its own weight.

Euler has ſhewn, that the common doctrine of reſiſtance anſwers very well when the motion is not very ſwift, but in very ſwift motions it gives the reſiſtance leſs than it ought to be, on two accounts. 1. Becauſe in very quick motions the air does not fill up the ſpace behind the body faſt enough to preſs on the hinder parts, that the reſiſtance on the fore part is increaſed. 2. The denſity of the air before the ball, being increaſed by the quick motion, will preſs more ſtrongly on the fore part, and, being heavier than in its natural ſtate, will retard its motion.

He has alſo ſhewn, that Mr. Robins has reſtrained his rule to velocities not exceeding 1670 feet in 1″; whereas, had he extended it to greater velocities, the reſult muſt have been erroneous: as he apprehends that it is not perfectly exact, when the motion is not extremely ſwift. He has inveſtigated a formula for determining the degree of this reſiſtance, and deduced concluſions differing from thoſe of Mr. Robins. See Principles of Gunnery inveſtigated, &c. 1777, p. 224, &c.

Mr. Robins having proved that, in very great changes of velocity, the reſiſtance does not accurately follow the duplicate proportion of the velocity, lays down two poſitions, which may be of conſiderable ſervice in the practice of artillery, till a more complete and accurate theory of reſiſtance, and the changes of its augmentation, may be obtained. The firſt of theſe is, that till the velocity of the projectile ſurpaſſes that of 1100 feet in a ſecond, the reſiſtance may be eſteemed to be in the duplicate proportion of the velocity: and the ſecond is, that if the velocity be greater than that of 1100 or 1200 feet in a ſecond, the abſolute quantity of the reſiſtance will be nearly three times as great as it ſhould be by a compariſon with the ſmaller velocities. Upon theſe principles, he proceeds in approximating the actual ranges of pieces with ſmall angles of elevation, *viz.* ſuch as do not exceed 8° or 10°, which he ſets down in a table, compared with their correſponding potential ranges. See his Mathematical Tracts, vol. i. p. 179, &c.

Since

Since the above experiments of Mr. Robins, Dr. Hutton has profecuted the fubject to a much greater length. His experiments were made not only with the whirling machine invented by the former, but with cannon balls of different weights, from 1lb. to 6lbs.; as alfo with figures of various fhapes, and with planes fet at a variety of angles of inclinations to the path of motion. From thefe experiments the author has afcertained the refiftance of bodies to all velocities, from 1 to 2000 feet *per* fecond; the bodies being different, and their faces at different angles of elevation. Some of his general tables, and conclufions from thofe experiments, are as follows.

Table I. Of Refiftances of different Bodies.

In this table are contained the refiftances of feveral forms of bodies, when moved with feveral degrees of velocity, from 3 feet *per* fecond to 20 feet *per* fecond. The names of the bodies are at the tops of the columns, as alfo which end went foremoft through the air; the different velocities are in the firft column, and the refiftance, on the fame line in their feveral columns in avoirdupois ounces and decimal parts. Thus, on the firft line are contained the refiftances when the bodies move with a velocity of three feet in a fecond; *viz.* in the fecond column, for the fmall hemifphere of $4\frac{3}{4}$ inches diameter, its refiftance .028 ounces, when the flat fide went foremoft; in the third and fourth columns, the refiftances to a large hemifphere, firft with the flat fide, and next with the convex part foremoft; the diameter of this, as well as all the following figures, being $6\frac{5}{8}$ inches, and therefore the area of the great circle = 32 fquare inches, or $\frac{2}{9}$ of a fquare foot; then in the fifth and fixth columns are the refiftances of a cone, firft, with its vertex, and then with its bafe foremoft; the altitude of the cone being $6\frac{5}{8}$ inches, the fame as the diameter of its bafe; in the feventh column, the refiftance to the end of the cylinder; and in the eighth, that againft the whole globe or fphere. All the numbers fhew the real weights which are equal to the refiftances; and at the bottoms of the columns are placed proportional numbers, which fhew the mean proportions of the refiftances of all the figures to each other with any velocity. Laftly, in the ninth column are placed the exponents of the power of the velocity which the refiftances in the eighth column bear to each other, *viz.* which that of the 10 feet velocity bears to each of the following ones; the medium of all them being as the 2.04 power of the velocity; that is, very little above the fquare, or fecond power, fo far as the velocities in this table extends.

From this table the following inferences are readily deduced.

1. That the refiftance is nearly in the fame proportion as the furfaces; a fmall increafe only taking place in the greateft furfaces, and for the greater velocities: thus, by comparing together the numbers in the fecond and third columns for the bafes of the two hemifpheres, the areas of which bafes are in the proportion of $17\frac{3}{4}$ to 32, or 5 to 9 very nearly, it appears that the numbers in thefe two columns, expreffing the refiftances, are nearly as 1 to 2, or 5 to 10, as far as the velocity of 12 feet: but after that, the refiftances on the greater furface increafe gradually more and more above that proportion.

2. The refiftance to the fame furface, with different velocities, is, in thefe flow motions, nearly as the fquare of the velocity; but gradually increafes more and more above that proportion, as the velocity increafes. This is manifeft from all the columns; and from the index of the power of the velocity fet down in the ninth column for the refiftances in the eighth, the medium of which being 2.04, fhews that the refiftance to the fame body is, in thefe flow motions, as the 2.04 power of the velocity, or nearly as the fquare of it.

3. The round ends, and the fharp ends, of folids, fuffer lefs

lefs refiftance than the flat or plane ends of the fame diameter; but the fharper end has not always the leaft refiftance. Thus, the cylinder, and the flat ends of the hemifphere, and cone, have more refiftance than the round or fharp ends of the fame, but the round fide of the hemifphere has lefs refiftance than the fharp end of the cone.

4. The refiftance on the bafe of the hemifphere is to that of its convex part, as $2\frac{1}{7}$ to 1, inftead of 2 to 1, as given by theory. The experimented refiftances alfo exceed the theoretical by nearly $\frac{1}{4}$th.

5. The refiftance on the bafe of the cone is to that on its vertex, nearly as $2\frac{3}{10}$ to 1, which is the fame as the ratio of the fine of the angle of inclination of the fide of the cone to its axis; fo that, in this inftance, the refiftance is as the fine of the angle of incidence.

6. When the hinder parts of different bodies are of different forms, the refiftances are different, although the fore parts be exactly the fame; owing probably to the different preffures of the air on the hinder parts.

Thus the refiftance to the fore-part of the cylinder is lefs than on the equal flat furface of the cone, or of the hemifphere; and the refiftance on the bafe of the hemifphere lefs than that of the cone; and the round fide of the hemifphere lefs than the whole fphere.

TABLE II. Refiftance, both by Experiment and Theory, to a Globe of 1.965 Diameter.

Velocity per Second in Feet.	Refiftance by Experiment in Ounces.	Refiftance by Theory in Ounces.	Ratio of Experiment to Theory.	Refiftance as the Power of the Velocity.

2000	1569	786	2.00	2.098

In the firft column of this table are contained the feveral velocities, gradually, from 5 feet *per* fecond to the greateft velocity of 2000 feet *per* fecond, with which a globe or ball is moved. In the fecond column are the experimented refiftances in avoirdupois ounces. In the third, the correfponding refiftances as deduced from theory. In the fourth column the ratio of thefe two refiftances, or the quotients of the former divided by the latter; and the fifth, or laft, the indices of the power of the velocity which is proportional to the experimented refiftances, and which are found by comparing the refiftance of 20 feet velocity with each of the following ones.

The following tables are of a fimilar kind, but the experiments are repeated on balls of different fizes.

TABLE III.—Refiftances to a ball of 1.965 inch diameter, and 16 oz. 13 dr. weight.

Velocity.	Refiftances.		1ft Dif.	2d Dif.

The

The analogy among the numbers in all theſe tables is very remarkable and uniform, the ſame general law obtaining in them all, by means of which, together with our preceding remarks, we may anſwer many intereſting queſtions relating to this ſubject, as connected with artillery practice. For example, ſuppoſe it were required to determine what would be the reſiſtance of the air againſt a 24lb. ball, diſcharged with a velocity of 2000 feet *per* ſecond. By Table III. the ball of 1.965 inch diameter, when moving with 2000 feet velocity, ſuffered a reſiſtance of 98lbs.; then ſince the reſiſtances, with the ſame velocity, are as the ſurfaces, and the ſurfaces as the ſquares of the diameters; alſo the diameter of a 24-pound ball being 5.6 inches, we have as $(1.965)^2 : (5.6)^2$, or as $3.86 : 31.36 :: 98\text{lbs.} : 796\text{lbs.}$, the reſiſtance which a 24lb. ball experiences when diſcharged with the above velocity. And generally, if the diameter of any propoſed ball be d inches, and r the tabular reſiſtance correſponding to any velocity v; then we ſhall generally have as $(1.965)^2 : d^2 :: r : \frac{r\,d^2}{(1.965)^2} = \frac{r\,d^2}{3.8}$, or very nearly $\frac{1}{4} r\,d^2$.

Theſe reſiſtances relating to certain and determinate velocities, a principal object of inveſtigation has been, amongſt experimentaliſts, to determine ſome rule or formula by which the reſiſtance may be found for any velocity whatever, and the reſult of Dr. Hutton's inveſtigations on this ſubject is as follows, *viz.*

Reſiſtance $= r = .00002576\,v^2 - .00388\,v$, in avoirdupois pounds, the velocity being v.

This rule $.00002576\,v^2 - .00388\,v = r$ denotes the reſiſtance for a ball whoſe diameter is 1.965 inch, the ſquare of which is 3.9 or 4 nearly. Hence to adapt it to any other ball, whoſe diameter in inches is d, we ſhall have, by the ſame proportion as above, $\frac{d^2}{3.8}\,(.00002576\,v^2 - .00388\,v) = (.00000667\,v^2 - .0010)\,d^2 = (.00000\tfrac{2}{3}\,v^2 - .001\,v)\,d^2$, for the reſiſtance of any ball whoſe diameter is d, and velocity v.

In ſmaller velocities the ſame author finds the theorem $.00001725\,v^2 = r$ ſufficiently correct, and this is adapted to a ball whoſe diameter is d in exactly the ſame manner, giving the reſult $.00000447\,d^2\,v^2 = r$ for the reſiſtance when the velocities are ſmall.

For the application of theſe theorems to the ſolution of certain problems connected with the doctrine of *projectiles*, ſee that article: and for various other formulæ and reſults equally curious and intereſting, ſee Dr. Hutton's Tracts, as alſo vol. iii. of his Courſe of Mathematics; Robins' Gunnery; Moore's Theory of Rockets; Gregory's Mechanics; and Prony's Architecture Hydraulique.

Resistance, *Different, of the ſame Medium to Bodies of different Figures.*—Sir Iſaac Newton ſhews, that if a globe and a cylinder, of equal diameters, be moved with equal velocity in a thin medium, conſiſting of equal particles, diſpoſed at equal diſtances, according to the direction of the axis of the cylinder; the reſiſtance of the globe will be leſs by half than that of the cylinder.

Resistance, *Solid of the leaſt.*—From the laſt propoſition the ſame author deduces the figure of a ſolid which ſhall have the leaſt reſiſtance of any containing the ſame quantity of matter and ſurface.

The figure is this. Suppoſe D N F G (*Plate* XXXVI. *Mechanics, fig.* 15.) to be ſuch a curve, as that if from any point N be let fall a perpendicular N M to the axis A B; and from a given point G be drawn a right line G R parallel to a tangent to the figure in N, and cut the axis, when continued, in R; M N be to G R as G R *cub.* to 4 B R × G B *q*; a ſolid deſcribed by the revolution of this figure about its axis A B, moving in a medium from A towards B, is leſs reſiſted than any other circular ſolid of the ſame area, &c.

This theorem, which ſir Iſaac Newton has given without a demonſtration, has been demonſtrated by ſeveral mathematicians, as Fatio, Craig, M. d'Hoſpital, Bernouilli, &c. (See Dr. Horſley's edition of Newton, vol. ii. p. 390, and Maclaurin's Fluxions, ſect. 606 and 607.) For a more particular inveſtigation of this ſolid, ſee prob. 6. under the article Isoperimetry.

Resistance *of a Globe* perfectly hard, and in a medium whoſe particles are ſo too, is to the force with which the whole motion may either be deſtroyed, or generated, which it has at the time when it has deſcribed four-thirds of its diameter, as the denſity of the medium to the denſity of the globe. Hence, alſo, ſir Iſaac Newton infers, that the reſiſtance of a globe is, *cæteris paribus*, in a duplicate ratio of its velocity. Or its reſiſtance is, *cæteris paribus*, in a duplicate ratio of its diameter; or, *cæteris paribus*, as the denſity of the medium. Laſtly, that the actual reſiſtance of a globe is in a ratio compounded of the duplicate ratio of the velocity, and of the duplicate ratio of the diameter, and of the ratio of the denſity of the medium.

In theſe articles the medium is ſuppoſed to be diſcontinuous, as air probably is: if the medium be continuous, as water, mercury, &c. where the globe does not ſtrike immediately on all the particles of the fluid generating the reſiſtance, but only on thoſe next it, and thoſe again on others, &c. the reſiſtance will be leſs by half: and a globe in ſuch a medium undergoes a reſiſtance which is to the force with which the whole motion it has after deſcribing eight-thirds of its diameter, might be generated, or taken away, as the denſity of the medium to the denſity of the globe.

Resistance *of a Cylinder,* moving in the direction of its axis, is not altered by any augmentation or diminution of its length; and therefore is the ſame with that of a circle of the ſame diameter, moving with the ſame velocity in a right line perpendicular to its plane.

The reſiſtance of a cylinder, moving in an infinite non-elaſtic fluid, ariſing from the magnitude of a tranſverſe ſection, is to the force with which its whole motion, while it deſcribes four times its length, may be taken away, or generated, as the denſity of the medium to that of the cylinder, very nearly.

Hence, the reſiſtance of cylinders moving lengthwiſe, in infinitely continued mediums, are in a ratio compounded of the duplicate ratio of their diameters, the duplicate ratio of their velocities, and ratio of the denſity of mediums.

The reſiſtance of a globe, in an infinite non-elaſtic medium, is to the force by which its whole motion, while it deſcribes eight-thirds of its diameter, might be either generated or taken away, as the denſity of the fluid to the denſity of the globe, *quam proximè.*

Resistance *of Matter.* (See Matter.) The meaning of this expreſſion is not, that matter makes any *oppoſition* to a change of its ſtate, or exerts a force to maintain itſelf in the ſtate it is, as ſome have very improperly expreſſed themſelves. This would imply that activity which is inconſiſtent with its nature; and if it were true, a part of the force of every impulſe would be ſpent merely in overcoming this oppoſition, without producing any other effect; and, therefore, the ſum of the motions the ſame way would always be greater before than after colliſion, which is impoſſible. The *largeſt* body will be moved by any the

ſlighteſt

ſlighteſt impulſe of the *ſmalleſt;* but then it can be moved only in proportion to the force of the impulſe, and this is what is chiefly meant by the *reſiſtance* of matter: *e. gr.* a body at reſt will *reſiſt* another which is moving towards it; that is, it will be an *obſtruction* to the motion of this other; the latter will be retarded by the former, and will loſe juſt as much motion as it communicates. In other words; the reſiſtance of matter is that in its nature which makes it require an *adequate foreign* cauſe of every change of ſtate, or from whence it is *wholly paſſive*, and incapable of receiving any motion from impulſe, that is not in a certain fixed proportion to the *relative momentum* of the impelling body, and ſtrictly equal to the change of ſtate it ſuffers in conſequence of the impulſe. In this proportion matter is always moved *without difficulty;* but beyond this there is not only a *difficulty*, but an *impoſſibility* of moving it; and whatever motion it can be ſuppoſed to receive from any impulſe that is greater than that which the impelling body loſes, it muſt derive from nothing at all. The activity which is denied to matter, is a power of changing its own ſtate, not that of acting upon other matter by *impulſe*. This ſort of activity, or power, follows from, and is neceſſarily implied in its perfect paſſiveneſs or inertia. See Price's Diſſertations, p. 35, note.

Non-Resistance, in *Politics*. See Passive *Obedience*.

RESITU, in *Geography*, a town of Naples, in the province of Capitanata; 16 miles N.N.W. of Vieſte.

RESLEU, a river which riſes in Bavaria, and runs into the Egra, in Bohemia.

RESOLIF, a town of Scotland, in the county of Cromarty; 7 miles W. of Cromarty.

RESOLVENTS, Resolventia, in the *Materia Medica*, remedies proper to reſolve and diſſipate tumours and gatherings; to ſoften indurations, and, by their tenuity and warmth, evacuate redundant or peccant humours through the pores.

Under this claſs come various unguents, emplaſters, &c.

RESOLUTION, Resolutio, or *Solutio*, in *Phyſics*, the reduction of a body into its original or natural ſtate, by a diſſolution or the ſeparation of its aggregated parts.

Thus ſnow and ice are ſaid to be reſolved into water; and a compound is reſolved into its ingredients, &c.: water reſolves into vapour by heat; and vapour is again reſolved into water by cold.

Some of the moderm philoſophers, particularly Mr. Boyle, M. Mariotte, Boerhaave, &c. maintain that the natural ſtate of water is to be congealed, or in ice; inaſmuch as a certain degree of heat, which is a foreign and violent agent, is required to make it fluid: ſo that near the pole, where this foreign force is wanting, it conſtantly retains its fixed or icy ſtate. On this principle, the reſolution of ice into water muſt be allowed an improper expreſſion.

Resolution, in *Chemiſtry*, is the reduction of a maſs, or mixed body, into its component parts, or firſt principles, by proper analyſis.

The reſolution of bodies is performed variouſly; by diſtillation, ſublimation, diſſolution, fermentation, &c. See each operation under its proper article. See alſo Dissolution and Solution.

Resolution, in *Ethics*, is that paſſion which encounters difficulties and dangers; but when it has to do more peculiarly with dangers, it is called boldneſs. Deſire, joy, and ſorrow, enter into its conſtitution; but joy is much the principal ingredient. When reſolution degenerates into a concern to maintain our miſtakes, humours, or vices, it is more properly denominated obſtinacy. See Passions.

Resolution, in *Logic*, is a branch of *method*, called alſo *analyſis*.

The buſineſs of reſolution is to inveſtigate or examine the truth or falſehood of a propoſition, by aſcending from ſome particular known truth, as a principle, by a chain of conſequences, to another more general one in queſtion. Reſolution, or the analytic method, ſtands in direct oppoſition to *compoſition*, or the ſynthetic method; in which laſt we deſcend from ſome general known truths to a particular one in queſtion.

For an inſtance of the method of reſolution; ſuppoſe the queſtion this: Whether, on the ſuppoſition of man's exiſtence, we can prove that God exiſts?

To reſolve this, our method is thus: Mankind did not always exiſt. It is evident, from a thouſand conſiderations, the ſpecies had a beginning; and that, according to all hiſtory, not ſix thouſand years ago; but if it had a beginning, there muſt be ſome cauſe of its beginning; ſomething to induce it to exiſt then more than it did before; in effect, there muſt be a cauſe or author of its exiſtence; for from nothing, nothing ariſes: this cauſe, whatever it is, muſt, at leaſt, have all the faculties we find in ourſelves; for none can give more than he has: nay, he muſt have others, which we have not, ſince he could do what we cannot do, *i. e.* create, make man exiſt, &c. Now, this cauſe either exiſts ſtill, or has ceaſed to do ſo: if the former, he did not exiſt from eternity; for what is from eternity is neceſſary, and can neither by itſelf, nor any other cauſe, be reduced to nothing: if the latter, it muſt have been produced from ſome other; and then the ſame queſtion will return upon the producer. There is then ſome firſt cauſe, and this cauſe has all the properties and faculties we have; nay more, has exiſted from eternity, &c. Therefore, from the ſuppoſition of man's exiſtence, it follows that there is a God.

Resolution, or *Solution*, in *Mathematics*, is an orderly enumeration of ſeveral things to be done, to obtain what is required in a problem.

Wolfius makes a problem to conſiſt of three parts. The *propoſition* (which is what we properly call the *problem*), the *reſolution*, and the *demonſtration*.

The general tenor of all problems is, thoſe things being done which are injoined by the reſolution, the thing is done which was to be done.

As ſoon as a problem is demonſtrated, it is converted into a theorem; of which the reſolution is the hypotheſis; and the propoſition the theſis.

The proceſs of a mathematical reſolution, ſee in the following article.

Resolution, in *Algebra*, or *algebraical*, is of two kinds; the one practiſed in numerical problems, the other in geometrical ones.

Resolution *of Equations*, is the determination of the values of the unknown letters or quantities of which it is compoſed; in order to which it is neceſſary, firſt, to exterminate or eliminate all the unknown quantities but one out of the equation, and then the value of the remaining quantity is to be found by the proper rules for this purpoſe, *viz.* by the rules given for *ſimple*, *quadratic*, *cubic*, or *biquadratic equations*, according to which of theſe it may belong; or, by the general method of *approximation*, for which ſee the reſpective articles. But as all theſe caſes have reference only to one unknown quantity, it will not be amiſs, in this place, to explain ſome of thoſe methods which are moſt commonly employed for reducing equations to one unknown.

Firſt, it may be obſerved, that in any determinate problem there are always as many equations independent of each other, as there are unknown quantities; if there are not ſo many, the queſtion is *indeterminate*, and if there be more, it is *impoſſible*.

We cannot, in a limited article like the present, give all the methods that may be employed for exterminating the unknown letters; these being extremely various, and depending much upon the practice and proficiency of the analyst himself, and the manner in which those quantities are involved; but the most applicable and general methods are the three following, *viz.*

1. Find the value of one and the same unknown quantity in each equation, and put all these values equal to each other, which will eliminate one of the quantities, and reduce the number of equations to one less. Then do the same in these new equations; and again in the last; and so on, till there be but one equation and one unknown quantity, the value of which must be found by the proper rules, as above referred to.

2. Find the value of one of the unknown quantities in one of the equations, in terms of the other quantities; then substitute this value for that quantity in all the other equations; again, find the value of one of the remaining quantities, and substitute its value as before; and so on, till there remains but one equation and one unknown quantity, whose value is to be found as before.

3. Multiply each of the equations by such numbers as will render the co-efficients of one of the letters the same in all; then, by adding or subtracting these equations according as the equal co-efficients have unlike or like signs, the quantity whose co-efficients were equal will disappear; which being repeated again upon the remaining quantities, there will ultimately be found only one equation and one unknown quantity. And it may be proper to observe, that in all these cases, if any of the unknown quantities have fractional co-efficients, the whole equation in which they are found should be multiplied by such a number as will convert these fractions into integers.

Thus, in the equations

$$\begin{aligned} \tfrac{3}{5}x + \tfrac{2}{15}y &= 10 \\ \tfrac{1}{2}x + 3y &= 95 \end{aligned}$$

multiply the first by 15, and the latter by 2, gives

$$\begin{aligned} 9x + 2y &= 150 \\ x + 6y &= 190 \end{aligned}$$

the solution of which, by each of the preceding rules, will be as follows.

Or, putting letters instead of the above numerical co-efficients, in order to render the solution more general, let there be given

$$\left.\begin{aligned} ax + by &= c \\ dx + ey &= f \end{aligned}\right\} \text{to find } x \text{ and } y.$$

1st method. $\left.\begin{aligned} ax &= c - by \\ dx &= f - ey \end{aligned}\right\}$ by transposition.

$$x = \frac{c - by}{a} = \frac{f - ey}{d} \text{ by division.}$$

$$dc - dby = af - aey, \text{ by multiplication.}$$

$$(ae - db)\,y = af - dc$$

$$y = \frac{af - dc}{ae - db}$$

And in the same manner we find,

$$x = \frac{ec - bf}{ae - db}$$

2d method. $\left.\begin{aligned} ax + by &= c \\ dx + ey &= f \end{aligned}\right\}$ to find x and y.

$$x = \frac{c - by}{x} \text{ as above.}$$

$$\frac{dc - dby}{a} + ey = f, \text{ by substit.}$$

$$dc - dby + aey = af, \text{ by multiplication.}$$

$$(ae - db)\,y = af - de$$

$$y = \frac{af - dc}{ae - db} \text{ as before.}$$

$$x = \frac{ec - bf}{ae - db}$$

3d method. $\left.\begin{aligned} ax + by &= c \\ dx + cy &= f \end{aligned}\right\}$ to find x and y.

$$dax + dby = dc, \text{ mult. by } d.$$

$$adx + acy = af, \text{ mult. by } a.$$

$$(db - ac)\,y = dc - af$$

$$\left.\begin{aligned} y &= \frac{dc - af}{db - ae} = \frac{af - dc}{ae - db} \\ x &= \frac{bf - ec}{db - ae} = \frac{ec - bf}{ae - db} \end{aligned}\right\} \text{as before.}$$

This will, in some measure, illustrate the preceding rules, which we shall not insist upon any further; but, in the following examples, shall avail ourselves of any advantages that the equations present, in order to arrive at the solution in the easiest manner possible.

Examples.

1. Given $\left.\begin{aligned} x^2 + y^2 &= a \\ xy &= b \end{aligned}\right\}$ to find x and y.

$$x^2 + y^2 = a$$

$$2xy = 2b, \text{ doubling the 2d.}$$

$$x^2 + 2xy + y^2 = a + 2b, \text{ by addition.}$$

$$x^2 - 2xy + y^2 = a - 2b, \text{ by substit.}$$

$$\left.\begin{aligned} x + y &= \surd\,(a + 2b) \\ x - y &= \surd\,(a - 2b) \end{aligned}\right\} \text{by extraction.}$$

$$x = \frac{\surd\,(a + 2b) + \surd\,(a - 2b)}{2}$$

$$y = \frac{\surd\,(a + 2b) - (a - 2b)}{2}$$

2. Given $\left.\begin{aligned} x + y &= a \\ xy &= b \end{aligned}\right\}$ to find x and y.

$$x^2 + 2xy + y^2 = a^2, \text{ by squaring.}$$

$$4xy = 4b, \text{ mult. by 4.}$$

$$x^2 - 2xy + y^2 = a^2 - 4b, \text{ by substit.}$$

$$x - y = \surd\,(a^2 - 4b), \text{ by extract.}$$

$$x + y = a, \text{ 1st equat.}$$

$$x = \frac{a + \surd\,(a^2 - 4b)}{2}$$

$$y = \frac{a - \surd\,(a^2 - ab)}{2}$$

3. Given $\left.\begin{aligned} x - y &= a \\ xy &= b \end{aligned}\right\}$ to find x and y.

$$x^2 - 2xy + y^2 = a^2, \text{ squaring.}$$

$$4xy = 4b, \text{ mult. by 4.}$$

$$x^2 + 2xy + y^2 = a^2 + 4b, \text{ by adding.}$$

$$x + y = \surd\,(a^2 + 4b), \text{ by extract.}$$

$$x - y = a$$

$$x = \frac{a + \surd\,(a^2 + 4b)}{2}$$

$$y = \frac{a - \surd\,(a^2 + 4b)}{2}$$

4. Given

4. Given $\left.\begin{matrix} x - y = a \\ x^2 + y^2 = b \end{matrix}\right\}$ to find x and y.

$x^2 - 2xy + y^2 = a^2$, fquaring.
$2x^2 \qquad + 2y^2 = 2b$, doubling.
$x^2 + 2xy + y^2 = 2b - a^2$, fubtr.
$x + y = \sqrt{(2b - a^2)}$
$x - y = a$

$$x = \frac{a + \sqrt{(2b - a^2)}}{2}$$

$$y = \frac{a - \sqrt{(2b - a^2)}}{2}$$

This method of refolution will apply in many problems, and fometimes faves confiderable labour.

5. Given $\left.\begin{matrix} x^2 + xy = a \\ y^2 + xy = b \end{matrix}\right\}$ to find x and y.

$x^2 + 2xy + y^2 = a + b$, by adding.
$x + y = \sqrt{(a + b)}$, by extract.
$(x + y)\,x = x\sqrt{(a + b)} = a$
$(x + y)\,y = y\sqrt{(a + b)} = b$

$$x = \frac{a}{\sqrt{(a + b)}}, \text{ and } y = \frac{b}{\sqrt{(a + b)}}.$$

6. Find three numbers in arithmetical progreffion, whofe fum is a, and fum of their fquares b.

Let $x - y$, x and $x + y$, be the numbers required.

Then $x - y + x + x + y = 3x = a$
$(x - y)^2 + x^2 + (x + y)^2 = 3x^2 + 2y^2 = b$

$$x^2 = \frac{a^2}{9} = \frac{b - 2y^2}{3}$$

Whence $a^2 = 3b - 6y^2$

and $$y = \sqrt{\frac{3b - a^2}{6}}, \text{ and } x = \frac{a}{3}.$$

And a fimilar fubftitution, *viz.* one which anfwers one of the conditions of the queftion, may frequently be employed to great advantage.

7. Sometimes it will be convenient to fubftitute for the fums and differences of numbers, as in the following example.

Given $\left.\begin{matrix} x + y = a \\ x^4 + y^4 = b \end{matrix}\right\}$ to find x and y.

Let $x + y = 2m$ and $x - y = 2n$ $\Big\}$ then $\left\{\begin{matrix} x = m + n \\ y = m - n \end{matrix}\right.$

$$(m + n)^4 + (m - n)^4 = b,$$
$$\text{or } 2m^4 + 12m^2n^2 + 2n^4 = b;$$

but $2m = a$, or $m = \frac{a}{2}$; therefore m is known, and the above becomes

$$2n^4 + 12m^2n^2 = b - 2m^4$$
$$n^4 + 6m^2n^2 = \tfrac{1}{2}b - m^4$$
$$n^2 = -3m^2 \pm \sqrt{(\tfrac{1}{2}b + 8m^4)}$$
$$\text{and } n = [3m^2 \pm \sqrt{(\tfrac{1}{2}b + 8m^4)}]^{\frac{1}{2}}.$$

Whence m and n being known, x and y are alfo known; for $x = m + n$, and $y = m - n$.

8. Sometimes it is advantageous to confider one of the quantities as an unknown multiple of the other; thus:

Given $xy = x^2 - y^2 = x^3 + y^3$, to find x and y.

Make $y = zx$, then thefe become

$$\left.\begin{matrix} zx^2 = x^2 - z^2x^2 \\ zx^3 = x^3 + z^3x^3 \end{matrix}\right\}$$
$z = 1 - z^2$, from the firft,
$z^2 + z = 1$, or $z = -\frac{1}{2} + \frac{1}{2}\sqrt{5}$;

whence z is a known quantity. Now,

$z = x + z^3x$, from the fecond,

$$x = \begin{cases} \dfrac{z}{1 + z^3} = \dfrac{-\frac{1}{2} + \frac{1}{2}\sqrt{5}}{1 - (\frac{1}{2} - \frac{1}{2}\sqrt{5})^3} \\[2ex] \dfrac{-\frac{1}{2} + \frac{1}{2}\sqrt{5}}{-1 + \sqrt{5}} = \frac{1}{2} \end{cases}$$

$y = zx = -\frac{1}{4} + \frac{1}{4}\sqrt{5}$, as required.

Sometimes it faves confiderable labour, to find the fum, product, or difference, of the two quantities, inftead of the quantities themfelves; thus:

9. Given $x^2 + y^2 - x - y = a$
$xy + x + y = b$;

by addition $x^2 + xy + y^2 = a + b$
$x^2 + 2xy + y^2 = a + b + xy$
$x + y = \sqrt{(a + b + xy)}$;

but $x + y = b - xy$;

therefore $b^2 - 2bxy + x^2y^2 = a + b + xy$
$x^2y^2 - (2b + 1)\,xy = a + b - b^2$:

whence $$xy = \frac{2b + 1}{2} \pm \sqrt{\left(\frac{2b + 1}{2}\right)^2 + a + b - b^2}.$$

Now make $xy = p$ a known quantity, and we have, from the fecond equation,

$$p + x + y = b,$$
$$\text{or } x + y = b - p$$
$$xy = p$$

whence $x^2 - 2xy + y^2 = (b - p)^2 - 4p$
$x - y = \sqrt{[(b - p)^2 - 4p]}$
$x + y = b - p$

therefore $$x = \frac{b - p + \sqrt{[(b - p)^2 - 4p]}}{2}$$

$$y = \frac{b - p - \sqrt{[(b - p)^2 - 4p]}}{2}.$$

Thefe, and a variety of other artifices peculiar to certain equations, will occur to the practical analyft; of which, numerous examples may be feen in Bland's Algebraical Problems, as alfo in Bonnycaftle's and Euler's Algebra.

RESOLUTION *of a geometrical Problem algebraically.* The procefs in the former article is to be obferved throughout; but as it rarely happens we come at an equation in geometrical problems by the fame means as in numerical ones, there are fome farther things to be noted: 1ft, then, fuppofe the thing done, which was propofed to be done. 2. Examine the relations of all the lines in the diagram, without any regard to known or unknown, in order to find which depends on which; and from which being had, what others are had, whether by fimilar triangles, or rectangles, &c. 3. To obtain the fimilar triangles or rectangles, the lines are to be frequently produced, till they become either directly or indirectly equal to given ones, or interfect others, &c. Parallels and perpendiculars to be frequently drawn; points to be frequently connected; and angles to be made equal to others. If thus you do not arrive at a neat equation, examine the relation of the lines in another manner.

Sometimes

Sometimes it is not enough to feek the thing directly, but another thing muft be fought, whence the firft may be found.

The equation being reduced, the geometrical conftruction is to be deduced from it, which is done in various manners, in the various kinds of equations. See APPLICATION *of Algebra to Geometry*.

RESOLUTION, *Problematical*. See PROBLEMATICAL.

RESOLUTION, in *Medicine*, the termination of an inflammation, without any change in the texture of the part inflamed, in contradiftinction to the termination in fuppuration or gangrene. The great object of medicine, in all inflammatory difeafes, in the commencement, is to obtain the refolution of the inflammation, fo that the ftructure and functions of the part affected may not be injured by the difeafe: and the means of obtaining a refolution, when the inflammation is feated in an internal part, are evacuations of blood by the lancet, cupping, or leeches; and of ferum, by purging the bowels, applying blifters in the vicinity, &c.; and when the inflammation is external, by local evacuations by fimilar means, and by the application of cold fubftances. See INFLAMMATION.

RESOLUTION, in *Mufic*, is when a canon or perpetual fugue is not written all on the fame line, or in one part; but all the voices that are to follow the guida, or firft voice, are written feparately, either in fcore, *i. e.* in feparate lines, or feparate parts, with the paufes each is to obferve, in the beginning, and in the tone proper to each.

The refolution of difcords, in mufic, is generally by their defcent upon concords; except the *tritonus*, or fharp 4th, and the *note fenfible*, or fharp 7th of a key, which afcend, while the bafe defcends or remains ftationary.

RESOLUTION, in *Surgery*, the moft favourable manner in which the procefs of inflammation can terminate, confifting of a gradual abatement of the pain, rednefs, fwelling, throbbing, and heat of the part, without any formation of matter, and without any floughing. Alfo, the difperfion of fwellings and indurations, through the medium of abforption.

RESOLUTION *of Motion*, in *Mechanics*. See MOTION.

RESOLUTION *Bay*, in *Geography*, a name given by captain Cook to the port of Madre de Dios, fituated near the middle of the W. fide of St. Chriftina, one of the Marquefas iflands, in the South Pacific ocean, and under the higheft land in the ifland, in S. lat. 9° 55′ 30″, W. long. 139° 8′ 40″, and N. 15° W. from the W. end of La Dominica. The fouth point of the bay is a fteep rock of confiderable height, terminating at the top in a peaked hill, above which may be feen a path-way leading up a narrow ridge to the fummit of the hills. The north point is not fo high, and rifes with a more gentle flope. They are a mile from each other in the direction of N. by E., and S. by W. In the bay, which is near three quarters of a mile deep, and has from 34 to 12 fathoms water, with a clean fandy bottom, are two fandy coves, divided from each other by a rocky point. In each is a rivulet of excellent water. The northern cove is the moft commodious for wooding and watering. Here is the little water-fall mentioned by Quiros, Mendana's pilot; but the town, or village, is in the other cove. There are feveral other coves or bays on this fide of the ifland; and fome of them, efpecially to the northward, may be miftaken for this: therefore the beft direction is the bearing of the weft end of La Dominica. Cook's Voyage, vol. i. p. 307.

RESOLUTION *Ifland*, one of the newly-difcovered Society iflands, in the South Pacific ocean. S. lat. 17° 24′. W. long. 141° 15′.—Alfo, an ifland in the North Atlantic ocean, 60 miles in circumference, fituated on the N. fide of the entrance into Hudfon's ftraits. N. lat. 61° 40′. W. long. 65°.

RESOLUTION *Port*, a bay or harbour of the ifland of Tanna, in the South Pacific ocean. S. lat. 19° 32′. E. long. 169° 40′.

RESONANCE, in *Mufic*, is founding again, repeating or continuing the found. The refonance of a ftring, a bell, or other fonorous body, ceafes with the vibration.

It expreffes the found returned by the air inclofed in the bodies of ftringed mufical inftruments, as lutes, &c.; or even in the bodies of wind inftruments, as flutes, &c.

Elliptic and parabolic vaults refound ftrongly, *i. e.* they ftrongly reflect or return the found. See ECHO.

The mouth, and the parts thereof, as the palate, tongue, teeth, nofe, and lips, Monf. Dodart obferves, contribute nothing to the tone of the voice; but their effect is very great as to the refonance.

Of this we have a very fenfible inftance in that vulgar inftrument called *Jews-harp*, or *trompe de Bearn*: for if you hold it in your hand, and ftrike the tongue or fpring thereof, which yields all the found of the inftrument, it fcarcely makes any noife at all; but, holding the body of the inftrument between the teeth, and ftriking the fpring as before, it makes a mufical buzz, which is heard to a good diftance, and efpecially in the lower notes.

So alfo in the hautboys, the tone of the reed is always the fame; being a fort of drone: the chief variety is in the tone of the refonance, produced in the mouth by the greater or lefs aperture, and the divers motions of the lips.

RESORT. See RESSORT.

RESOUZE, in *Geography*, a river of France, which runs into the Saone, near Pont de Vaux, in the department of the Ain.

RESP, a difeafe in fheep, the fame as red-water. See RED-*Water*.

RESPECT, in *Ethics*, denotes that favourable impreffion which the goodnefs of a character has made upon the perfon contemplating it, united with a fhare of good fenfe. An union of both thefe qualities is neceffary to create refpect. Goodnefs alone is not fufficient to produce it; for if it be feated in a mind that indicates extreme imbecility, it cannot be deemed refpectable. On the other hand, fuperior fenfe in a mind deftitute of goodnefs, will not infpire refpect: it will either wafte itfelf in idle fpeculations, which renders it indifferent to us; or it may degenerate into low cunning, which renders it hateful. Should it be connected with power in a wicked and perverfe mind, it will excite horror and difmay, which are very remote from refpect.

RESPECTU *computi vicecomitis habendo*, in *Law*, a writ for the refpiting of a fheriff's accompt, upon juft occafion, directed to the treafurer and barons of the exchequer.

RESPECTUANDO HOMAGIO. See HOMAGIO.

RESPIRATION, in *Phyfiology*, that function of animal bodies, in which the air, either in its elaftic ftate, as it conftitutes the atmofphere, or held in folution in water, is brought into contact with fome organ or organs, undergoing alterations in its own conftitution, and producing changes in the nature of the animal fluids, which are effential to the continuance of life. In the mammalia, birds, and reptiles, the refpiratory organs confift of lungs, that is, of membranous cavities, differently conftructed in the three claffes, but agreeing in the circumftance of alternately receiving and emitting a portion of atmofpherical air. This alternate ingrefs and egrefs of air conftitutes properly what is called in common language *breathing*, to which the philofophical term *refpiration* is fynonimous. We extend the term to animals of the lower claffes, which have no lungs, and fome of of which do not even *breathe*, that is, do not receive and emit air at all. In confequence of the medium in which fifhes are immerfed, they cannot take in the atmofpheric air in its elaftic ftate, and they confequently have an apparatus, altogether different from that which exifts in the three claffes already named, for the purpofe of producing analogous effects in their economy. They are furnifhed with a paffage communicating with the fauces or œfophagus, and terminating in the external furface of the body, through which a part of the water received into the mouth is forcibly propelled. In this paffage, the branchiæ or gills are fituated; and the blood, which circulates in their fringed extremities, is thus expofed to the action of a quantity of air, which the water always holds in folution. Cruftaceous animals, and many of the mollufca, have organs more or lefs fimilar in ftructure and functions to the gills of fifhes. Infects, both in their larva and perfect ftates, poffefs numerous ramified tubes, diftributed over their whole body, and provided with open mouths, which admit the paffage to and fro of the external air. Although the ftructure of the organs in fifhes and infects is fo different from that which we find in mammalia, birds, and reptiles, they perform an analogous office, anfwer the fame general purpofes in the animal economy, and are confidered equally in the light of organs of *refpiration;* this term being employed now to denote the general effect produced by thefe various organizations, without any reference to the means through which it is produced; although it was originally applied to the paffage of the air to and from the lungs, when the refults of that procefs were unknown.

Is refpiration, confidered in its moft extenfive fenfe, a function neceffary to the exiftence of all animals? The refults of all the inveftigations hitherto made, induce us to anfwer this queftion in the affirmative; but the point is not yet demonftrated in all cafes.

In Cuvier's clafs of zoophytes, excepting the echinodermata, no refpiratory apparatus has been found; nor has any been yet difcovered in the inteftinal worms, or in fome of the external worms, as the leech, earth-worm, and others. It may be doubted, fince the analogy on which we ground our opinion of the neceffity of air to animal exiftence is fo very ftrong, whether the apparent exception afforded by the animals juft enumerated may not arife from our imperfect knowledge of their organization, and whether more accurate inquiries may not either difclofe to us in thefe cafes fome particular organ of refpiration, or fhew us that the function is performed by the external furface of the body in general. We know, in fact, by direct experiment, that fome of thefe animals produce changes in the air, and cannot live when debarred from its accefs.

The differences which animals exhibit in their mode of breathing, or in the manner of effecting the changes which their nutritive fluid undergoes from the action of the atmofphere, depend on other circumftances in their organization. Vegetables, and animals which have no circulation, *refpire* by their whole furface, or by means of veffels, which convey air to all points of their interior. Thofe only which have a true circulation breathe by a particular organ. The heart being in them a common point of departure and return for the blood, the veffels containing that fluid could eafily be fo arranged as to convey it to the lungs, after it had circulated through the body: this was obvioufly impracticable in inftances, when the nutritive fluid is every where uniformly expanded, without being contained in veffels. Hence refpiration by lungs or gills is a function dependent on that of circulation, and may be regarded as a remote confequence of thofe faculties which characterife animals.

Refpiration prefents to our obfervation two very different kinds of phenomena: 1ft, the motions of the lungs, gills, or other inftruments of breathing, or of parts connected with them, by which the former are alternately dilated and contracted for the admiffion and expulfion of air, and the latter are expofed to a current of water; and 2dly, the changes produced in the blood or other animal fluids, and in the air or water, in confequence of their mutual expofure in thefe organs. The firft may be termed the *mechanical*, and the fecond the *chemical* phenomena of refpiration. The former, including all the modifications which breathing undergoes in laughing, crying, and fighing, in coughing, fneezing, hiccoughing, in ftraining or holding the breath, &c. have been fully confidered under the article LUNG; in which the anatomy of the organs of refpiration in man is alfo fully detailed. In the articles MAMMALIA, BIRDS, FISHES, REPTILES, INSECTS, and VERMES, the breathing organs, and their mechanical phenomena in animals, are confidered. The chemical phenomena are the object of the prefent article.

The functions of the refpiratory organs are clofely connected with the other great proceffes of the animal economy. The heart, brain, and lungs, more particularly influence each other, and prefent, in their mutual relations, numerous and highly interefting confiderations for the phyfiologift. On thefe points we refer to HEART, LUNGS, and NERVOUS *Syftem*.

In the following article we fhall fpeak, 1ft, of the quantity of air received into the cheft; 2dly, of the changes which this undergoes in breathing, as they have been made out by refearches on the refpiration of man and the mammalia; 3dly, of the changes produced in the blood; 4thly, of the various explanations of the mode in which thefe changes are produced; 5thly, of the refpiration of the different gafes; 6thly, of the chemical phenomena of refpiration in other animals, and 7thly, of animal heat.

I. *Number of Refpirations, and Quantity of Air refpired.*—"It appears," fays Dr. Thomfon (Syftem of Chemiftry, v. 5. p. 732.), "that the number of refpirations made in a given time differs confiderably in different men. Dr. Hales reckons them at 20 in a minute. A man, on whom Dr. Menzies made experiments, breathed only 14 times in a minute. Mr. Davy informs us that he breathes between 26 and 27 times in a minute. I myfelf make about 19 refpirations at an average. The average of all is 20. Now 20 in a minute make 28,800 in 24 hours."

In his "Inquiry," p. 102, et feq. Mr. Ellis has brought together, from the moft authentic fources, a ftatement of the facts hitherto collected concerning the quantity of air ordinarily infpired. To afcertain this point, many modes of experiment have been adopted, and the conclufions which have been drawn from them very widely differ. Borelli eftimated the bulk of air taken in at a fingle infpiration at 15 cubic inches (de Mot. Animal.); Mr. Kite from 12 to 17 (Effay on Apparent Death, p. 24.); Dr. Goodwyn at 14 (Connection of Life with Refpiration, p. 28, et feq.); Mr. Davy from 13 to 17 (Refearches, p. 410 and 433.); and Drs. Jurine, Hales, Haller, and Sauvages, at 40 cubic inches. With the conclufion of thefe latter authors the experiments of Dr. Menzies nearly coincide, and as the methods which he adopted feem lefs liable to objection than thofe of any other author, it may not be improper fhortly to give the detail of them. He procured an allantoid, and fixed to it a machine confifting of two pretty large tubes, joined at right angles, nearly in the form of a common brafs cock. One end of the horizontal tube was connected with the allantoid, and the other received into the mouth, while the upright tube, which rofe from its centre, communicated

with

with the atmosphere. The tubes were large, and valves, made out of an allantoid, were affixed to the end of the upright tube, and to that attached to the allantoid, so that the air, when expelled from the lungs, should not escape into the atmosphere, nor return from the allantoid, after having once entered it. Precautions were taken also, by covering the mouth and nostrils, to prevent any air from passing in or out of the lungs, except by the tubes above mentioned. Things being thus prepared, he began to respire, and did not remove his mouth from the tube till he had filled the allantoid, taking care to stop his nostrils during expiration. The allantoid was filled, in repeated trials, by about 56 expirations, as natural as possible; and as its capacity was 2400 cubic inches, the average bulk of air thrown out of the lungs by each expiration, was 42.8 cubic inches. He then fixed another allantoid, whose capacity had been previously ascertained, to the end of the upright tube; and having filled it with atmospheric air, he inspired the air from one allantoid and expired it into the other, and the quantities were found to be nearly the same. Several persons of the middle size repeated this experiment with nearly the same result; the difference being scarcely ever more than one or two cubic inches. By another mode of experiment, first proposed by Boerhaave, of plunging a man into a tub of water up to his chin, and judging of the dilatation of the lungs from the ascent and descent of the water, he obtained, by several trials, nearly the same results; and when these same men were made to breathe from and into the allantoids, in the manner above described, the correspondence by the two methods was almost complete. (Menzies on Respiration, p. 21, et seq.) As there seems no obvious source of inaccuracy in the processes here employed, and their results so remarkably coincide; and as they present the average bulk deduced from 56 respirations, we may conclude, says Dr. Bostock, that 40 cubic inches is the quantity of air employed in an ordinary act of respiration. Essay on Respiration, p. 34. Inquiry into the Changes, &c. § 85.

Messrs. Allen and Pepys endeavoured to determine the quantity of air received into the lungs in an ordinary inspiration: 3460 cubic inches of atmospheric air were passed through the lungs in 11 minutes, by 58 respirations. As, on ordinary occasions, the person breathed 19 times in a minute, it is inferred that, by multiplying the time consumed in the experiment by the number of natural respirations in a minute, and dividing the whole bulk of air by the product, we obtain the true bulk of air received into the lungs at each natural inspiration; thus $11 \times 19 = 209$; and $\frac{3460}{209} = 16.5$ cubic inches, the quantity of a single natural inspiration. (Phil. Transf. 1808, p. 256.) Mr. Ellis justly observes, that not only do the efforts of the mind, and the operations of the apparatus, interfere greatly with the natural actions of the respiratory organs, but the gross quantity of air received in 58 preternatural inspirations can never with justice be assumed as a true measure of the quantity breathed in 209 natural respirations. The experiments of Dr. Menzies therefore still seem the most unexceptionable on this subject.

The difficulty in arriving, by experiment, at certain conclusions respecting the volume of air taken into the lungs in each inspiration, may arise from a difference in the state or capacity of those organs in different individuals; from the relative vigour or debility of the muscular powers carrying on the respiratory function; from the circumstances in which the animal is placed; the composition of the air itself; or the manner in which it is breathed. In many modes of experiment also, the friction between the air and apparatus employed, or the resistance which this latter may create to the ordinary process, will greatly vary the result: and considerable errors must likewise have arisen from the variation in bulk, occasioned by the change of temperature, which the air, during its respiration, suffers; from the difficulty of breathing in a natural manner when the mind is directing that process; and from the embarrassments opposed to the natural action of the respiratory organs by the contrivances adapted to them.

It will not be denied, that the size and capacity of the chest must, in a certain degree, regulate the quantity of air which is taken into, or expelled from it; and since respiration is neither wholly a voluntary nor an involuntary act, but, within certain limits, partakes of the nature of both, and is carried on by the exertion of muscular powers, the bulk of respired air must vary also, either from an alteration in the action of these powers, or from a change in the will of the agent who exerts them. This may be illustrated by considering the different quantities of air taken into the lungs in different states of natural and forced respiration. Dr. Goodwyn, supposing a person at death to make a *complete* expiration, endeavoured to ascertain the bulk of air then remaining in the lungs, which he estimated at 109 cubic inches. (Connection of Life with Respiration, p. 27.) This estimate he formed by measuring the capacity of the chest, in subjects who had died a natural death by disease, previous to which the expiratory powers must have been much weakened, and unable, in consequence, to expel so much air as when in a state of health and vigour; and in such cases, therefore, expiration might be final without being complete. Mr. Cruickshank observes, accordingly, that the lungs in the dead body, (though expiration is the last action of life,) always retain more air than is given out at several expirations. (On Insensible Perspiration, p. 97.) By a very different mode of experiment, we find Mr. Davy to conclude that his lungs, after a forced expiration, contain only 32 cubic inches of air, when it is reduced to the temperature of 55°, but which, by the heat of the lungs, and saturation with moisture, are increased to 41 cubic inches; and, after a natural expiration, they contained 118 cubic inches (Researches, p. 409, 410.); so that the difference between the two states of natural and forced expiration is 77, which is somewhat more than Dr. Menzies allows, who remarked that many men, after an ordinary expiration, could still expel from their lungs 70 cubic inches of air. (Diss. on Respiration, p. 31.) Mr. Davy adds, that his estimate of 118 cubic inches, as the capacity of the lungs after natural expiration, agrees very well with that of Dr. Goodwyn, who makes it about 109; and, on the supposition that the general debility which precedes the ordinary extinction of life, so weakens the expiratory muscles, as to disable them from making so complete an expulsion of the air, as they can effect when in health and vigour, the agreement is very striking; for nearly the same quantity of air would, in that case, remain in the lungs at the period of natural death, as after that of ordinary expiration.

Messrs. Allen and Pepys found that the healthy lungs of a stout man, five feet ten inches high, contained 108 cubic inches of air after death. Phil. Transf. 1809, p. 410, et seq.

Dr. Bostock conceives, that Dr. Goodwyn's estimate of 109 cubic inches of air remaining in the lungs after complete expiration, is not very remote from the truth; and he objects to Mr. Davy's mode of ascertaining the residual air of the lungs after a forced expiration, from a supposition that the hydrogen gas which he inspired for that purpose was not, in consequence of its low specific gravity, uniformly

formly diffused through all the cavities of the lungs; and therefore, that the proportions of the gas discharged could furnish no accurate estimate of those which were retained. (Essay, p. 17—25.) But Mr. Dalton has shewn, that hydrogen gas and atmospheric air intermix, when the former is kept in a phial above the latter, and communicating only by the small tube of a tobacco-pipe; and both in a state of rest. (Manchester Memoirs, vol. i. new series.) How much more readily then may this be expected to take place, where the gases are exposed to so large a surface, such great agitation, and increased temperature, as they must have been in the experiments of Mr. Davy. Neither is the small quantity of air, which Mr. Davy assigns, so incompatible, as Dr. Bostock supposes, with the anatomical structure of the thorax; for if we call to mind the space which the heart and the lungs occupy, and recollect, that, under a violent exertion, the chest is made to contract in every direction, and more especially by the ascent of the diaphragm nearly to the fourth or fifth rib, there is no difficulty in imagining the quantity of air in the lungs, in such circumstances, to be nearly that which Mr. Davy's experiments assign.

From a review, therefore, of all the facts and experiments above stated, we venture to draw the following conclusions, as approaching nearest to the truth. First, then, according to Mr. Davy, the lungs contain, after a forced expiration, a bulk of air equal to about 41 cubic inches; and according to the same author and Dr. Goodwyn, they contain, after a natural expiration, from 109 to 118 cubic inches; therefore the state of forced is to that of natural expiration, as 41 to 118. Secondly, according to Dr. Menzies, 40 cubic inches of air are received into the lungs at each ordinary inspiration; therefore the state of natural expiration to that of natural inspiration will be as 118 to 158. Mr. Davy found likewise, that by a forced expiration after a forced inspiration, he could expel from his lungs 190 cubic inches of air, and Dr. Menzies often found it to amount to 200 inches; therefore the state of greatest exhaustion of the lungs is to that of greatest repletion, as 41 to 231. But the 41 cubic inches of air, when inspired at temperature 55°, occupied a bulk equal only to 32; and therefore, by the same rule of proportion, 190 cubic inches, inspired at the same temperature, will be increased to 241.5; consequently, the greatest diminution of the capacity of the chest to its greatest expansion will be as 41 to 241, in the case of Mr. Davy. But these numbers must be considered as indicating proportions only, the absolute quantities being different in different persons. These facts decidedly shew how much the volume of air in the lungs will, at all times, depend on the relative capacity of those organs, on the more or less vigorous state of the expiratory powers, and on the degree of voluntary exertion with which the function may be performed.

The circumstances in which the animal may happen to be placed, will render this variation still more striking. Thus, from the experiments of Mr. Kite (On Apparent Death, p. 27. 29.) and Mr. Coleman (On Suspended Respiration, p. 7, et seq.), we learn, that in the act of drowning, animals are able to expel almost all the air which their lungs contain, by which those organs are brought into a state of collapse. Dr. Goodwyn, on the other hand, found, that in three executed persons, the lungs were expanded almost to their utmost extent, containing 250, 262, and 272 cubic inches of air (Essay, p. 25.); and Mr. Coleman observes, that when, previous to their suspension, he secured the trachea of animals by a ligature at the instant an inspiration was made, in less than four minutes they ceased to struggle, though the whole of the air was confined within the lungs, and no obstruction to the passage of the blood existed from their collapse (p. 111—138). Dr. Baillie also has often observed the lungs filling the chest, and distended with air and mucus, in persons who have died asthmatic; so that to die and to expire are by no means synonimous terms,—an observation long since made by Mayow, who remarked, that if air be drawn into the lungs, and the mouth and nostrils afterwards closed, "quamvis inflati maneant pulmones, mori tamen necesse erit, quia non licet expirare." (Tractat. Quinque, p. 300.) If indeed we reflect, that during submersion in water no fresh air can enter into the lungs, but that all which they contain may freely escape; and if we consider, that before suspension by the neck in the human subject, a deep inspiration, under the influence of fear, as Dr. Goodwyn observes, is made, and that no air can afterwards pass out, if the cord completely close up the trachea; it is reasonable to expect, that this variation in the bulk of air contained in the lungs should obtain, under the very different circumstances in which respiration is brought to a stand.

How much the composition of the air itself, and the manner in which it is breathed, will vary the bulk of residual air in the lungs, we may collect from the experiments of various authors. Dr. Hales moistened a bladder, and fixed to it a fosset, both of which would contain 74 cubic inches of air. Having blown up the bladder, he put the small end of the fosset into his mouth, and, at the same time, pinched his nostrils close, that no air might escape through them, and he then breathed to and fro. the air contained in the bladder. In less than half a minute, he found a considerable difficulty of breathing, and was forced after that to draw his breath very fast; and at the end of the experiment, the suffocating uneasiness was so great as to oblige him to take away the bladder from his mouth. Towards the end of the minute, the bladder was become so flaccid that he could not blow it above half full, with the greatest expiration that he could make. (Statical Essays, vol. i. p. 238.) When also Mr. Davy respired atmospheric air in a natural manner, he took in, he says, only 13 cubic inches and expelled 12.7, so that only about $\frac{1}{13}$d part of the original bulk was retained; when he made one respiration of 100 cubic inches of air, the diminution was to 99, or $\frac{1}{100}$; when, after a complete exhaustion of his lungs, he respired 141 cubic inches of air, once only for one-fourth of a minute, they were reduced to 139, or $\frac{1}{70}$th nearly; and when 161 cubic inches were breathed for about a minute, their bulk was diminished to 152, or $\frac{1}{18}$th (Researches, p. 432—435.);—in every case, the diminution augmenting with the repetition of the respiration, and consequent impurity of the air, and distress of the respiratory organs. So likewise, when Dr. Henderson breathed from and into the gasometer 600 cubic inches of air for four minutes, they were reduced to 570, or lost $\frac{1}{20}$th of their bulk; and he adds, that he held on respiring until the sense of oppression about the chest obliged him to desist. (Nicholson's Journal, May 1804.) These distressing symptoms, brought on by the repeated breathing of the same quantity of air, were felt in a still greater degree by Mr. Kite; for on respiring 591 cubic inches of atmospheric air from and into a bladder, he experienced, in one minute, great anxiety at the breast, which in half a minute more became intolerable; his face swelled, became black, and felt excessively hot, and sparks of fire danced before him; loss of sight, giddiness and confusion of the senses succeeded, and at the end of little more than two minutes, he fell back into a chair. He was relieved by fresh air, but remained confused and giddy (Essay on Apparent Death, p. 25.) The amount of the diminution

of

of refpired air, fays profeffor Pfaff, depends not only on the *time* during which a given volume of air is refpired, but principally on the magnitude of the volume of air itfelf; it muft be proportionally lefs the greater the quantity infpired. He breathed 144 cubic inches of air once only in the time of ten or twelve feconds, and the diminution was four cubic inches, or $\frac{1}{36}$th of the primitive volume; when he refpired the fame volume of air twice, during twenty feconds, it loft eight cubic inches, or $\frac{1}{18}$th; and when it was thrice refpired, during thirty feconds, the diminution amounted to twelve cubic inches, or $\frac{1}{12}$th of the primitive volume. (Nicholfon's Journal, December 1805.) Now, in all thefe cafes, the volume of air refpired was precifely the fame, and could not, therefore, affect the ratio of diminution: but as the times were doubled and tripled, fo nearly were the degrees of diminution. But the more frequently the fame air is breathed, the more unfit does it become for refpiration; and to this change of compofition, more than to the time, or the magnitude of the volume of air, is the increafed degree of diminution to be afcribed.

This will perhaps appear more ftriking, if we attend to what happens in refpiring nitrous oxyd, which is compofed of the fame elements as atmofpheric air, but contains a much larger proportion of oxygen. After exhaufting his lungs, Mr. Davy infpired 108 cubic inches of this gas, which, when expired, were reduced to 99, or had loft $\frac{1}{12}$th of their bulk. When he made two refpirations of the fame quantity of the oxyd, the diminution was to 95, or about $\frac{1}{8}$th; and when he refpired 102 cubic inches of nitrous oxyd, mixed with $\frac{1}{30}$th of common air, for half a minute, the volume of air, after the feventh expiration, was reduced to 62, or had fuffered a lofs equal to $\frac{1}{2.55}$. (Refearches, pp. 394. 416.) Hence it appears, that in the natural refpiration of atmofpheric air, only a fmall diminution of its bulk takes place: that this diminution increafes as the air becomes vitiated by repeated refpirations, or is breathed in a preternatural manner: and that when a gas of the fame elementary materials, but combined in very different proportions, is fubftituted into the place of pure atmofpheric air, the diminution increafes in a tenfold degree. Now, the repeated breathing of the fame atmofpheric air, has been fhewn to bring on the moft diftrefsful fymptoms, and at length an utter inability to continue refpiration; and Mr. Davy tells us, that after a voluntary exhauftion of his lungs, he could refpire the nitrous oxyd with accuracy, when ftooping, for about half a minute, but, even then, ftrong fenfations were produced, with fulnefs about the head rather alarming: that if the refpiration extended to three-fourths of a minute, he could not rely on the accuracy of any experiment; and that the determination of blood to the head became, in lefs than a minute, fo great as often to deprive him of voluntary power over the mufcles of his mouth. (Refearches, p. 392.) But refpiration is a function carried on by the exertion of mufcular powers, in a great degree obedient to the will; and the quantity of refidual air in the lungs in preternatural refpiration will at all times be much influenced by the manner in which the will exerts itfelf, and the degree in which the mufcles are able to act. When, therefore, the power of the will over the mufcles is in any degree diminifhed, or is wholly loft, or the mufcles themfelves are much weakened, a proportional derangement will take place in the refpiratory function; and as, in the natural condition of the body, expiration is fubfequent to infpiration, the ability to infpire will laft longer than the ability to expire: confequently the ceffation of the procefs is brought about by a failure in the expiratory powers. But if the expiratory powers are unable to expel the air from the lungs, it muft remain in thofe organs; and hence we fee in all the foregoing examples, that the diminution in the volume of expired air was greater in proportion as the refpiratory organs fuffered diftrefs or oppreffion, and amounted even to more than one-third of the air infpired, when all voluntary powers ceafed. Inquiry, &c. § 86—92.

From the above data it may be eftimated, that by each ordinary expiration one-feventh part of the whole contents of the lungs is difcharged, and that by the moft violent expiration fomewhat more than four-fevenths of the air contained in them is evacuated. Suppofing that each refpiration occupies about three feconds, a bulk of air nearly equal to three times the whole contents of the lungs will be expelled in a minute, or about 4114 times their bulk in 24 hours. The quantity of air refpired during the diurnal period will be 1,152,000 cubic inches, or $666\frac{1}{2}$ cubic feet.

II. *Changes produced in the Air.*—Although the ancients were not unacquainted with the general fact, that refpiration produces a change in the air received into the lungs, the firft accurate notions refpecting this change, were furnifhed by the experiments of Boyle. He not only proved, by means of the air-pump, the abfolute neceffity of air to the fupport of animal life, but he farther difcovered, that the action of the lungs is quickly fufpended, unlefs they are furnifhed with a regular fupply of frefh air. (Works, v. 1. p. 99, et feq.) "Animals, whofe hearts have two ventricles, and no foramen ovale," fays Mr. Derham, "as birds, dogs, cats, and mice, die under the action of the air-pump in lefs than half a minute, counting from the very firft exfuction, particularly in a fmall receiver." (Phyfico-Theology, p. 8.) The fame pofition is corroborated by an experiment, exhibited before the Royal Society by Dr. Hooke. He cut away the ribs, diaphragm, and pericardium of a dog, whereby the lungs and heart were brought into view; and then dividing the windpipe, he introduced into it the nozzle of a pair of double bellows, and made, at the fame time, feveral fmall punctures through the outer coat of the lungs. By blowing in a ftream of frefh air, which continued to efcape through the fmall apertures made in the lungs, he was enabled to keep thofe organs fully diftended. As long as he fupplied the lungs with air, the actions of life continued, and the heart beat very regularly; but, on intermitting the fupply, the dog would immediately fall into dying convulfive fits; and revive again as foon as the lungs were filled with a ftream of frefh air. The circulation through the lungs continued both during their diftended and collapfed ftate, and as well when they were kept at reft, as during their ftate of motion; whence he concluded, that neither the motion of the lungs, nor the ceffation of their motion, nor the ftopping of the circulation of the blood through them, was the immediate caufe of death; but the want of a fufficient fupply of frefh air. Lowthorp's Abridg. Phil. Tranf. v. 3. p. 66.

From thefe facts it was naturally concluded, that the air had undergone fome important change during its continuance in the pulmonary veficles, and a variety of hypothefes and conjectures were formed to account for this alteration. The knowledge which was then obtained refpecting the air was, however, almoft entirely confined to its mechanical properties, fo that the theories of refpiration, formed during this period, were neceffarily crude and imperfect. Boyle perceived that the air, in paffing through the lungs, became loaded with a quantity of aqueous vapour, and he farther fuppofed, that it acquired, what he calls, recrementitious fteams (Works, v. 3. p. 371, et feq.); but refpecting ſpecting the nature of theſe ſteams he forms no conjecture. He obſerved alſo, that the air in which an animal had reſpired for ſome time, was conſiderably diminiſhed in volume, an effect which he attributed to the loſs of part of its elaſticity or ſpring. The contemporaries of Boyle, for the moſt part, coincided with him in his ideas reſpecting reſpiration; there were, however, ſome philoſophers, who ſuppoſed, that beſides the addition of theſe vapours, the air, during its continuance in the lungs, imparted ſomething to the blood. Among theſe, the firſt in point of genius and originality was Mayow of Oxford. He inveſtigated the properties of the air, and the effects produced upon it by reſpiration, with great acuteneſs, and concluded, that a peculiar volatile ſpirit, which was one of the conſtituents of the atmoſphere, was abſorbed by the blood during its paſſage through the lungs. Borelli, Lower, Willis, and others, adopted opinions in many reſpects ſimilar to that of Mayow; they imagined, that either a portion of the whole maſs of air, or ſome particular conſtituent of it, was abſorbed by the blood, and by this means converted this fluid from the venous to the arterial ſtate. But ſo little real knowledge was at this time poſſeſſed reſpecting the compoſition of the atmoſphere, that they entirely failed in their attempts to aſcertain the nature of the matter abſorbed, and their hypotheſes appeared ſo extravagant, and ſo little founded upon truth, that their doctrines fell into diſcredit, became neglected, and at length were totally forgotten. De Motu Anim. p. *2a*. prop. 113. De Corde, p. 159—165. Willis, Pharm. Rat. p. ii. p. 34.

Dr. Hales devoted much of his attention to this ſubject, and performed many experiments with a view to illuſtrate the manner in which the air is affected by the lungs; he concludes nearly as Boyle had done, that it acquires a noxious vapour, and that its elaſticity is diminiſhed. (Statical Eſſays.) The learned Boerhaave confeſſes his inability to explain the changes which the air experiences by reſpiration. (Prælect. t. 5. p. 169, et ſeq.) The opinion of Haller was not materially different from that of Boyle and Hales; he had collected all the different theories which have been advanced upon this ſubject, and after reviewing them with his accuſtomed candour and perſpicuity, he concludes, that the air, when it is emitted from the pulmonary veſicles, is combined with a quantity of water, and a peculiar noxious vapour, and has its elaſticity diminiſhed. (Notæ ad Boerhaav. Prælect. t. 5. p. 170. Element. Phyſiol.) Such was the imperfect ſtate of our knowledge, when Haller wrote his Elements of Phyſiology! This noble monument of induſtry and genius was ſcarcely publiſhed, when Dr. Black commenced his experiments upon fixed air, and among other intereſting diſcoveries, ſatisfactorily proved, that this peculiar gaſeous ſubſtance is generated in the lungs during reſpiration.

"So early as the year 1757," ſays this diſtinguiſhed philoſopher, "I convinced myſelf, that the change produced in wholeſome air by breathing it, conſiſts chiefly, if not ſolely, in the converſion of part of it into fixed air; for I found, that by blowing through a pipe into lime-water, or a ſolution of cauſtic alkali, the lime was precipitated, and the alkali rendered mild." (Black's Lectures, by Robiſon, v. 2. p. 87.) At a later period, Mr. Bewley detected the formation of carbonic acid in reſpiration by a method ſomewhat ſimilar: he found, that on breathing through an infuſion of litmus, the ſame change to a red colour was produced in it, as when it was expoſed to the action of fixed air; and when, by adding a few drops of the water of potaſſa, the blue colour was reſtored to the infuſion, it could again be made to diſappear by ſuperſaturating it with the acid expired from the lungs. Prieſtley on Air, v. 5. p. 383.

The particular ſubſtance which conſtituted the wholeſome part of atmoſpheric air, was not, however, known to Dr. Black at the time his experiments were made: and long before the compound nature of the atmoſphere was aſcertained, it had been ſuppoſed by many philoſophers, that, to uſe the language of biſhop Berkeley, "there was no ſuch thing as a pure ſimple element of air. There is," he adds, "ſome one quality or ingredient in the air on which life more immediately and principally depends. What that is, though men are not agreed, yet it is agreed it muſt be the ſame thing that ſupports the vital and the common flame; it being found that when air, by often breathing in it, is become unfit for the one, it will no longer ſerve for the other. This quality of the air is neceſſary both to vegetables and animals, whether terreſtrial or aquatic; neither beaſts, inſects, birds, nor fiſhes, being able to ſubſiſt without air: and when air is deprived of this ingredient, it becometh unfit to maintain either life or flame, even though it ſhould retain its elaſticity." (Siris, § 143, et ſeq. 2d edition.) Dr. Hooke aſſerted, that this ingredient or ſubſtance, inherent in, and mixed with the air, is like, if not the very ſame, with that which is fixed in ſaltpetre, by which, during combuſtion, inflammable bodies are diſſolved. (Micrographia, p. 103.) The ſame opinion was afterwards held by Willis, Lower, and Mayow, all of whom likewiſe conſidered the nitrous quality of the air to act an important part in reſpiration. The laſt author, in particular, made experiments preciſely ſimilar to thoſe which have lately been brought forward to prove, that both by the burning of a candle, and other combuſtible bodies, and by the reſpiration of animals, the nitro-aërial particles of the air were exhauſted, whereby the volume of air was diminiſhed, and the reſidual air was unable afterwards to ſupport either life or flame. (Tractat. Quinque, p. 98, et ſeq.) The exhibition, however, of this peculiar, or nitro-aërial, part of the air in a diſtinct and ſeparate form, we owe to the genius of Scheele and Dr. Prieſtley, who diſcovered, independently of each other, in the year 1774, pure or dephlogiſticated air or oxygen gas. The atmoſphere, which, until this period, had been regarded as a homogeneous elementary body, was diſcovered by theſe celebrated experimenters, to be compounded of two aëriform fluids, poſſeſſing diſtinct properties, and having totally different purpoſes in the economy of nature. Theſe ſubſtances, which have ſince obtained the names of oxygenous and azotic gaſes, were found to exiſt in the atmoſphere, in the conſtant proportion of about 22 to 78. This great diſcovery, and the uſe which he made of it, enabled Dr. Prieſtley to propoſe the firſt conſiſtent explanation of the phenomena of reſpiration that had ever been offered to the public; and, although the theoretical opinions on which that explanation was partly founded, no longer exiſt, yet it ſhould never be forgotten that his experiments and diſcoveries firſt pointed out the true path of inveſtigation; and have contributed, in a pre-eminent degree, to advance our knowledge of this moſt important function. The cauſe of the unfitneſs of air, beyond a certain extent, to ſupport life and flame, he proved to ariſe from the deſtruction of its pure part, or what has ſince been called its oxygen gas; and he concluded, that, in reſpiration, combuſtion, and calcination, which, in conſequence of his peculiar theory, he ſtiles phlogiſtic proceſſes, it underwent preciſely the ſame changes. Philoſ. Tranſ. 1776. Obſ. on Air, v. 3. p. 9.

About a year after the publication of Dr. Prieſtley's experiments, the celebrated and unfortunate Lavoiſier preſented

ſented

sented a memoir on respiration to the French Academy of Sciences. (Mem. de l'Acad. des Sciences, 1777.) After paying a tribute of respect to the genius of Dr. Priestley, he proceeds to an accurate examination of his experiments, and the conclusions which were deduced from them. He agrees with the doctor in supposing, that the proportion of oxygen is diminished in air which has been respired, but upon a careful analysis of the residue, he finds it to differ from the air left after the calcination of metals, which is merely azotic gas, in containing a quantity of carbonic acid. He also observed, that the bulk of the air was somewhat diminished, and we learn in general from these experiments, that the changes produced in air by respiration, consist in the removal of part of the oxygen, in the addition of a quantity of carbonic acid gas, and in the diminution of its volume. He supposes that the azote is not affected by the process, and that it serves merely to dilute the oxygenous part of the atmosphere.

In this paper, M. Lavoisier does not mention the aqueous vapour which is so evidently discharged from the lungs by respiration; it is impossible that it could have been overlooked by so accurate an observer; we may therefore conjecture, that he omitted to mention it, because at this period he considered it as only diffused through the air expired from the lungs, by the process of evaporation, and not formed in consequence of the operation of any chemical affinities.

The conclusions of this philosopher respecting the changes produced by respiration upon the air taken into the lungs, are for the most part acquiesced in by modern physiologists, and the researches which have been since made upon this subject are principally directed, either to ascertain with more precision the proportion of the respective ingredients in the air of expiration, or to frame hypotheses to account for the operation of the lungs in effecting these changes.

Among the investigations, however, of a date subsequent to this memoir of Lavoisier, those of Messrs. Allen and Pepys, published in the Philosophical Transactions, 1808 and 1809, deserve peculiar mention, on account of their great accuracy, and the satisfactory manner in which they have consequently enabled us to determine some doubtful points.

Quantity of Oxygen consumed.—"A difficult and interesting question," says Dr. Bostock, "respecting the consumption of oxygen, is the absolute quantity of this gas consumed by respiration in a given time. The first calculations which were made upon this subject, in consequence of the imperfect nature of the apparatus employed, and of the want of a sufficient dexterity in the management of pneumatic experiments, were unavoidably vague and inaccurate. The difficulty was much increased by a circumstance first noticed by Dr. Crawford, and afterwards more fully investigated by M. Jurine of Geneva, and M. Lavoisier, that the respiration of the same animal in different states of the system, and under the operation of different external circumstances, affects the air in very different degrees. This curious fact, which affords an insight into some of the most important operations of the animal economy, must unavoidably produce great differences in the results of the best conducted experiments, and will render it impossible for us to arrive at more than an approximation to the truth. The circumstances which have been discovered to influence the chemical effects of the respiration are, the temperature of the air respired, the degree of muscular exertion, the state of the digestive organs, and the condition of the system as affected by fever; it is highly probable that other circumstances will be discovered, by multiplying and varying our experiments upon the living body."

An experiment performed by Lavoisier, upon a guinea pig, seems to have been the first in which a perfect apparatus, and the necessary degree of accuracy, were employed. (Mem. de l'Acad. des Sciences, 1780, p. 401—8.) The animal was confined over mercury, in a jar containing 248 cubic inches of gas, consisting principally of oxygen. In an hour and a quarter, the animal breathed with much difficulty, and being removed from the apparatus, the state of the air was examined. Its bulk was found to be diminished by eight cubic inches, and of the remaining 240 inches, 40 were absorbed by caustic potash, and consequently consisted of carbonic acid gas. Taking 100 parts of this air, these numbers will be as follows; the air was diminished to 96.5, or by 3.5 cubic inches, and of the remainder, 16.5 were converted into carbonic acid gas, and absorbed by potash, which reduces the quantity of air to 80 cubic inches. Towards the conclusion of the experiment, the air would be necessarily much less fit for performing the functions of the lungs than the air of the atmosphere, in consequence of the carbonic acid gas which it contained; but as the air employed was originally much purer than the atmosphere, the author supposes, that the quantity of oxygen destroyed, was probably about the same which would have been consumed under the ordinary circumstances of respiration.

The same philosopher performed a second experiment upon the same species of animal, with still more accuracy, in which pure oxygen was employed. (Ann. de Chimie, t. 5. p. 261, et seq.) This experiment continued during an hour and a half, and the animal being then removed from the jar, the air was analysed as in the former case: 1728 cubic inches of air were found to be reduced to 1673, *i. e.* had suffered a diminution of 55 inches, caustic potash absorbed about 229.5 inches, leaving a residue of pure oxygen. These numbers, estimated as in the former case, will be nearly as follows; 100 inches were reduced to 96.82, or by 3.18 inches, the potash absorbed about 19 inches, reducing the whole quantity of air to 77.82 parts. The quantity of carbonic acid was here somewhat greater than in the former experiment, which may be attributed to the air employed being pure oxygen, and to the process having been continued for a somewhat longer space of time than in the former instance. Upon the whole, the results correspond as nearly as can be expected, from the very delicate nature of the experiments.

Dr. Menzies first attempted to ascertain the quantity of oxygen consumed by a man, in the course of a day. He found by experiment, that one-twentieth part of air, which had been once respired, is converted into carbonic acid gas: this he concludes must have been oxygen, as that part of the air alone is affected by respiration. He conceives that 720 cubic inches of air are respired in a minute, of which consequently 36 will be consumed. From these data he estimates, that in the space of 24 hours, 51,840 cubic inches, or 17625.6 grains of oxygen, are consumed and converted into carbonic acid gas. In this calculation several important particulars appear to have been overlooked, and accordingly it will be found to differ from the results of the more accurate experiments, which have been since performed by M. Lavoisier, and Mr. Davy.

The experiments which were made by M. Lavoisier, in conjunction with his friend M. Seguin, were conducted with every possible attention to accuracy, and with an apparatus more complete than any which has ever been employed in physiological researches. An account of them is detailed in two papers in the memoirs of the Academy of Sciences

Sciences for the years 1789 and 1790; but notwithstanding the peculiar advantages under which they were performed, their results will not be found in all instances to coincide. M. Seguin was himself the subject of the experiments. The authors begin by pointing out the different effects which are produced by respiration, under the different circumstances in which the body is placed; and they farther remark, that individuals may probably differ in the absolute quantity of oxygen which they consume in the same circumstances. Making a due allowance for these variations, they conclude, that the mean consumption of oxygen by a man, during 24 hours, is somewhat more than 22 French cubic feet, or 46037.38 English cubic inches; a quantity of gas which will weigh 15661.66 grains troy.

Lavoisier was still continuing to pursue his experiments on this subject, and had constructed a very expensive apparatus, for ascertaining with still more precision the amount of the several changes produced by respiration, when he fell a sacrifice to the fury of Robespierre, and received sentence of death. He had already performed a number of experiments with his new apparatus, and earnestly requested a respite of a few days, in order to prepare them for publication; but his request was not granted. M. de la Place, who pronounced his eulogy, has fortunately given us the most important results: they will be found to differ in some particulars from the former experiments, though, with respect to the quantity of oxygen consumed, they nearly coincide. It is stated that a man in 24 hours consumes 15592.5 grains.

There are some experiments on this subject by Mr. Davy, which appear to have been executed with great accuracy. From a number of trials made upon his own respiration, he found, that 100 cubic inches of atmospheric air, after having once passed through the lungs, had lost between four and five parts of oxygen: hence he calculates, that 31.6 cubic inches of oxygen are consumed in a minute; this will give 45,504 inches in 24 hours, a quantity which will weigh 15471.36 grains. This estimate coincides nearly with that of M. Lavoisier, though it was obtained by a different process, and by the use of a different apparatus. We may, therefore, conclude, that between 45 and 46,000 cubic inches, or about 15,500 grains = 2 lbs. 8 oz. troy, is the average quantity of oxygen consumed by a man in 24 hours. Davy's Researches, p. 431—434. Essay on Respiration, p. 78—84.

In the series of experiments lately performed by Messrs. Allen and Pepys, an apparatus was employed, in which the volume of the air respired could be measured with great accuracy, and in which a large quantity (3 or 4000 cubic inches) could be respired; so that the source of error, to which experiments on a smaller scale are liable, from the influence of the residual air in the lungs, is much diminished. They caused a person to inspire, from a gasometer, 3460 cubic inches of atmospheric air, which were afterwards expired into another gasometer; and to both gasometers graduated scales were affixed, by which the quantities of air received and expelled could be accurately measured. The time occupied in the experiment was 11 minutes: about 58 respirations were made; and the deficiency in the whole volume of air, at the close of the experiment, amounted only to 23 cubic inches. One hundred parts of the expired air afforded, on analysis, 8.5 carbonic acid, 12.5 oxygen, and 79 nitrogen gas. (Phil. Transf. 1808, p. 254.) In an experiment on the respiration of another subject, the changes produced in the air were the same, but the quantity consumed was very different. The thermometer (Fahr.) being at 56°, and the barometer at 30°.3, 3300 cubic inches of atmospheric air were inspired, and 3311 expired in $5\frac{1}{2}$ minutes. One hundred parts of the expired air consisted of 8.5 carbonic acid, 12.5 oxygen, and 79 azote. When, therefore, twice the quantity of air was passed through the lungs in a given time, as great a proportion of its oxygen was consumed, and as much carbonic acid formed, as in a subject in whom only half the quantity was breathed. The experiment was repeated several times; and in one instance, 9890 cubic inches of air were breathed for $24\frac{1}{2}$ minutes, with the loss of only 18 cubic inches; and 100 parts of the expired air then afforded, on analysis, 8 carbonic acid, 13 oxygen, and 79 nitrogen. (Ibid. 257.) Now the air employed in these experiments contained, in 100 parts, 21 oxygen and 79 nitrogen; and in the numerous analyses, which were made of this air after its respiration, the portion of oxygen that disappeared was exactly replaced by that of carbonic acid produced; so that, in every instance, these two gases formed together $\frac{21}{100}$ths of the respired air, the remaining 79 parts being pure nitrogen gas. It is, therefore, concluded, that the quantity of carbonic acid gas emitted is exactly equal, bulk for bulk, to the oxygen consumed. Ibid. p. 279.

In subsequent experiments on the respiration of a guinea pig, these chemists found, that when 310 cubic inches of atmospheric air were breathed for 25 minutes by this animal, its volume experienced no variation whatever; and the portion of its oxygen, which disappeared, was replaced by an equal bulk of carbonic acid. (Phil. Transf. 1809, p. 414.) Three experiments were made on the respiration of the guinea pig, in two of which the time occupied was 25 minutes, and in the third one hour. The animal was confined in a certain volume of air, which was changed successively, so that the same air may have been breathed more than once; while in the experiments of these gentlemen on human respiration, just detailed, the air was only once breathed. In all the three experiments with the guinea pig, 100 parts of the air breathed contained the same constituent elements, *viz.* 5 carbonic acid, 16 oxygen, 79 azote. (Phil. Transf. 1809, p. 413, et seq.) Wherefore, they justly conclude, that when atmospheric air alone is respired, even by an animal subsisting wholly on vegetables, no other change takes place in it than the substitution of a certain portion of carbonic acid gas for an equal volume of oxygen. Ibid. p. 427.

In respiration as nearly natural as possible, these gentlemen estimate the quantity of oxygen consumed on an average at 26.6 cubic inches, at the temperature of 50°, and barometrical pressure of 30°.4.

The changes occurring in respiration are influenced by various causes, which modify the actions of the capillary vessels. Crawford established by experiment, that less oxygen is consumed at a high than at a low temperature (Experiments on Animal Heat, p. 307.); and this was confirmed in the experiments of Lavoisier and Seguin (Mem. de l'Acad. des Sciences, 1789, p. 575.); a man consuming, at the temperature of 54°, 1344 cubic inches of oxygen in an hour, while, in an atmosphere at the temperature of 79°, he consumed only 1210 cubic inches. Crawford observed also, that in an animal placed in a warm medium, the venous blood approached to the arterial in colour. Hence it appears, that the high temperature counteracts those chemical changes which the blood undergoes in the extreme vessels; and that the diminution in the consumption of oxygen by respiration is owing to this cause, and not, as has been supposed, to the rarity of the air at the high temperature. If the consumption of oxygen were diminished from the latter cause, the blood ought to be even more completely venous

 than

than uſual. The fact formerly known, that the conſumption of oxygen is influenced by the food and the ſtate of digeſtion, was confirmed and more accurately demonſtrated by Lavoiſier and Seguin. They found, that during digeſtion the conſumption of oxygen was increaſed to 1800 or 1900 cubic inches in an hour. Exerciſe, too, increaſed the proportion conſumed. It is ſtated that Seguin, in continuing the exerciſe of raiſing a weight of 15 pounds to a height of 613 feet during a quarter of an hour, conſumed 800 cubic inches, which is at the rate of 3200 in an hour; and the ſame exerciſe, made during digeſtion, occaſioned a conſumption equal to 4600.

Notwithſtanding, however, ſays Mr. Ellis, the neceſſity of oxygen gas to the continuance of reſpiration, and the great quantity of it that is thus daily conſumed, many facts tend to prove, that, by the very conſtitution of that function, a neceſſary limit is placed to its conſumption: and that this limit is determined, not by the purity of the air employed, but by ſome circumſtances inherent in the animal ſyſtem. It has been found, that the growth of vegetables is retarded by a great ſuperabundance of oxygen (Ellis's Inquiry, § 14–40.); and that, although inſects will live a conſiderable time in this gas, yet their breathing becomes oppreſſive, and they die (ibid. § 53.) long before the whole of it is conſumed. There can be little doubt but that the other claſſes of inferior animals would, under the ſame circumſtances, ſuffer in the ſame manner. In the experiment alſo made by Lavoiſier on the guinea pig, already deſcribed, the animal is ſaid to have breathed with much difficulty, although not more than one-fifth of the oxygen gas was conſumed: but ſome experiments of the ſame author, at a later period, ſeem in oppoſition to this fact. In comparing together the phenomena of combuſtion and reſpiration, he obſerves, that much more combuſtible matter is conſumed in a given time in vital air, than in that of the atmoſphere, but that the ſame circumſtance does not hold in reſpiration: for whether animals reſpire oxygen gas in its pure ſtate, or mixed with a proportion, more or leſs conſiderable, of nitrogen gas, the quantity of oxygen which they conſume is always the ſame. If a guinea pig, he adds, be kept for ſeveral days in oxygen gas, or in a mixture compoſed of fifteen parts nitrogen and one of oxygen, preſerving conſtantly theſe proportions, the animal in both caſes continues in his natural ſtate: his reſpiration and circulation do not ſenſibly appear to be either accelerated or retarded: his temperature remains the ſame, and he has only, when the proportion of nitrogen gas is too great, a ſlight diſpoſition to drowſineſs. Mem. de l'Acad. 1789.

The reſults of Mr. Davy's experience, however, do not correſpond with theſe concluſions of Lavoiſier. He introduced a mouſe into a jar containing an atmoſphere compoſed of 10.5 cubic inches of oxygen, and three inches of nitrogen gas. In half an hour the animal appeared to ſuffer much, and, in about an hour, lay down on his ſide, as if dying: in an hour and a quarter he was withdrawn from the jar alive, but motionleſs. The reſidual air, on being analyſed, was found to have loſt only 2.1 cubic inches of its oxygen gas, and conſequently 8.4 inches of that gas ſtill remained. Another mouſe, which was put at the ſame time into a jar containing 15.5 cubic inches of atmoſpheric air, was taken out through the mercury alive, but unable to ſtand, in 50 minutes: and on analyſing the reſidual air, 2.7 cubic inches of its oxygen were conſumed. Hence it appears, that the mouſe in atmoſpheric air conſumed nearly one-third more of oxygen in 50 minutes, than the other mouſe did in an hour and a quarter, when placed in a jar containing ſo large a portion of oxygen. (Reſearches, p. 443.) The reſults of theſe experiments on mice are corroborated by thoſe made by Mr. Davy on his own reſpiration; for he found, that he conſumed much leſs oxygen gas when he reſpired it pure, than when, for the ſame length of time, he breathed atmoſpheric air; and the quantity of carbonic acid formed in the firſt caſe, was but little more than half that obtained by the reſpiration, for the ſame time, of atmoſpheric air. (Ibid. 442.) Meſſrs. Allen and Pepys ſtate, on the contrary, that when pure oxygen gas is breathed, more of it is conſumed in a given time, and more carbonic acid formed, than in breathing atmoſpheric air. The experiments of Davy differ greatly therefore from thoſe of Lavoiſier as to the effects produced by the reſpiration of oxygen on the animal ſyſtem; for, while the latter philoſopher informs us, that this gas may be reſpired for many days without inconvenience, Mr. Davy has ſhewn that the animal dies long before the whole of it is conſumed. Truſting, therefore, to the accuracy of Mr. Davy's experiments, as in all reſpects ſupported by analogy, we infer, that an exceſs of oxygen gas in the air that is breathed, is not ſuited to the due maintenance of the reſpiratory function: and, on the other hand, the oppreſſive ſymptoms which the reſpration of impure air occaſions, as well as the reſults of Lavoiſier's experiments, in which nitrogen ſuperabounded, equally inſtruct us, that a deficiency of this gas is alike unſuited to it. Conſequently, we may conclude, that the atmoſphere, as it is naturally compoſed, is beſt adapted to the economy of the animal ſyſtem; but that this ſyſtem is, at the ſame time, ſo conſtituted, as to be able to bear great variations in the compoſition of the air without immediate injury to the powers of animal life.

When, however, this variation proceeds to a certain extent, the air is no longer capable of ſupporting vital action; but different animals, when confined in given volumes of air, poſſeſs the power of prolonging this action in very different degrees. Thus inſects, worms, fiſhes, and the amphibia, live until all the oxygen gas of the air is nearly or entirely conſumed (Ellis's Inquiry, § 53, et ſeq.); while birds die in a given quantity of air before they have conſumed two-thirds of its oxygen (ibid. § 84.), and a mouſe and guinea pig expire when about three-fourths of this gas have diſappeared. Dr. Prieſtley obſerved, that if a mouſe can ſtand the firſt ſhock of being put into impure air, or has been habituated to it by degrees, he will live a conſiderable time in air in which other mice will inſtantaneouſly die. (Experiments on Air, p. 257.) When, however, death does happen to animals in a given volume of air, it muſt ariſe either from the noxious operation of the nitrogen gas that is always preſent, or from that of the carbonic acid, which is formed; or it muſt proceed from the deficiency, or total abſence, of oxygen gas. Now, although nitrogen gas do not of itſelf ſupport life, yet we have no evidence that it exerts any injurious effects on the animal ſyſtem. In vegetation, and in the reſpiration of the inferior animals, it has been ſhewn to be wholly inactive; and when, in the experiment of Lavoiſier, it conſtituted $\frac{15}{16}$ths of the air employed, a degree of drowſineſs only ſeems to have been induced by it. That it is entirely paſſive, is ſtill farther confirmed by an experiment of Lavoiſier, who found that hydrogen gas, mixed in due proportion with oxygen, would ſerve the purpoſes of reſpiration as well as the air of the atmoſphere. We have no proof that nitrogen is able to enter the veſſels ſo as to produce any direct operation on the blood,—an effect which is ſtill farther forbidden by its incapacity of uniting with that fluid. We may therefore conclude, that nitrogen gas, when reſpired, neither ſuffers any change itſelf, nor produces any direct operation on the animal ſyſtem.

The

The only other gas to which the death of animals, in these circumstances, can be ascribed, is carbonic acid, which, however, when formed by respiration, does not seem destructive to animal life. Dr. Goodwyn observes, that when the same air is breathed several times, so as to increase the quantity of carbonic acid, its noxious operation is to be attributed not to the presence of this acid, but to the deficiency or absence of oxygen gas (Connection of Life, &c. p. 66.); and when Spallanzani, by means of an alkaline substance, abstracted this acid as soon as formed by the respiration of birds and quadrupeds, he did not find that they lived longer in a given bulk of air than when it was suffered to remain. (Memoirs on Respiration, p. 318.) Dr. Higgins observes, that debility, convulsions, and death, follow the successive diminution of the oxygen gas of the air in respiration, long before the whole of that gas is consumed, although the carbonic acid that is generated be, in the mean time, carefully withdrawn. (Minutes of a Society, p. 160.) Indeed, we might in this, as in former examples, be led to suppose, that neither the carbonic acid formed in respiration, nor the nitrogen gas employed in that process, would exert any positively destructive operation on the animal powers, since both of them must, at all times, necessarily be present in the system; and seeing, moreover, that the abstraction of oxygen gas alone is sufficient to account for the fatal effects which ensue, it must be deemed unnecessary to resort to the supposed agency of any subordinate cause. Inquiry, &c. § 127—130.

Quantity of Carbonic Acid produced.—Having ascertained the proportion of oxygen which is consumed in respiration, it next remains for us to determine the quantity of carbonic acid gas which is produced. It appears that Dr. Black first demonstrated its existence in air emitted from the lungs, and that Lavoisier afterwards examined it with more accuracy, and found that the air, in which an animal had expired, contained about one-sixth of its bulk of carbonic acid gas. (Acad. des Sciences, 1777.) In the experiment which this philosopher performed with a more perfect apparatus, upon a guinea pig confined in oxygen, the carbonic acid amounted to nearly one-fifth of the bulk of the whole air employed, when the animal had been detained in the apparatus until the air was reduced into a state no longer fit for respiration. (Annales de Chimie, t. 5. p. 261, et seq.) These experiments, however, only prove what proportion of carbonic acid gas will render air incapable of supporting life, without acquainting us with the quantity of this gas produced under the ordinary circumstances of respiration.

M. Jurine of Geneva, appears to have been the first who attempted to calculate the absolute quantity of carbonic acid formed by the respiration of man; he imagined that it constituted about one-tenth part of the air emitted from the lungs. (Encycl. Method. Médécine, v. 1. p. 494.) Dr. Menzies instituted a set of experiments to discover the absolute quantity generated in a given time; he infers from them, that $\frac{1}{20}$th part of air which has been once respired, is carbonic acid, and estimates, that a man, in 24 hours, sends out from the lungs 51,840 cubic inches, or nearly 4lbs. troy; but this estimate is probably over-rated. Essay, p. 50.

The circumstances which have been already pointed out, as influencing the consumption of oxygen, have at least as powerful an effect upon the production of carbonic acid gas. Accordingly we shall find the calculations of the most accurate experimenters upon this subject so widely different from each other, that it seems scarcely possible to arrive at any tolerable degree of certainty.

M. M. Lavoisier and Seguin, in their first memoir of 1789, estimate the average quantity of carbonic acid gas, formed by a man in 24 hours, at 17720.89 grains troy; in their subsequent memoir, published in the following year, this quantity is diminished to 8450.24 grains; and in the eulogy of Lavoisier by La Place, it is stated, that Lavoisier, in his last experiments, reduced it still lower, to 7550.40 grains. Mr. Davy, on the contrary, whose experiments seem to have been performed with great exactness, though with a less complicated apparatus than that employed by the French chemists, supposes the carbonic acid formed in 24 hours to amount to 17811.38 grains (Researches, p. 434.), a quantity which is not very different from that first announced by Lavoisier.

Mr. Murray found that he expired 265 cubic inches of air in 30 seconds, and he discovered in this 16.57 cubic inches of carbonic acid. Making a deduction for the small quantity of this acid contained in the inspired air, he assumes 16 cubic inches as the quantity formed by respiration in 30 seconds. He calculated the quantity of oxygen consumed at 19 cubic inches: the ratio, therefore, between the calculated quantity of oxygen consumed, and the actual quantity of carbonic acid formed, was as 100 to 84.5. Syst. of Chemistry, v. 4. p. 494.

Messrs. Allen and Pepys conclude from their experiments, that the atmospheric air expelled from the lungs usually contains from 8 to 8.5 *per cent.* of carbonic acid, and that the proportion of acid in no case exceeds 10 *per cent.* They estimate the quantity of acid thrown off in 11 minutes at 302 cubic inches, which is about 27.45 *per* minute; and supposing the production uniform for 24 hours, the total quantity in that period would be 39,534 cubic inches, weighing 18,683 grains, or rather more than 11 oz. troy. Phil. Trans. 1808.

If a larger quantity of air be passed through the lungs in a given time, more carbonic acid is formed, but it still preserves the same ratio to the other component parts of the expired mass. Thus, 3300 cubic inches of air were inspired by one person in $5\frac{1}{2}$ minutes, and as each 100 parts contained 8.5 of carbonic acid, the whole acid formed in this time was 281.42 cubic inches. The first and last portions of a single expiration differ considerably in their proportions of carbonic acid, because the former consists principally of air contained in the fauces, trachea, and its larger branches, while the latter comes from the air-cells themselves. In small quantities of the first portions, given off by natural and easy expirations, the carbonic acid formed from three to five *per cent.* When an expiration was made as complete as possible, the utmost efforts being employed to press the air out of the lungs, 204 cubic inches were expelled, and the proportion of carbonic acid was 9.5. Now as the first portions contain only from three to five *per cent.*, the last must have contained more than the average, or 9.5. When 300 inches of atmospheric air were repeatedly breathed, until the laborious state of respiration compelled the operator to desist, 100 parts of the expired air contained 9.5 carbonic acid, 5.5 oxygen, and 85 azote. When a similar trial was repeated until the operator became insensible, 100 parts of the air contained 10 carbonic acid, 4 oxygen, and 86 azote. (Phil. Trans. 1808.) When 3260 cubic inches of gas, consisting of 97.5 oxygen, and 2.5 azote in 100 parts, were respired for 9 minutes and 20 seconds, the expired air measured 3193 inches, and contained, in 100 parts, 11 carbonic acid, 83 oxygen, 6 azote. Here, therefore, 37.64 cubic inches of carbonic acid were emitted from the lungs in one minute by the same individual, who produced 27.45 *per* minute, when he breathed common air. In another instance, 3420 cubic inches of similar air were breathed for 7′ 25″:

the

the expired air meafured 3362. The firft 250 cubic inches confifted, in 100 parts, of 9 carbonic acid, 25 azote, 66 oxygen; the laft, of 12.5 carbonic acid, 5.5 azote, 82 oxygen: 100 parts of the whole expired air confifted of 12 carbonic acid, 6.5 azote, 81.5 oxygen. The whole quantity of carbonic acid gas emitted in this experiment was 396.78 cubic inches. Ibid.

The refult, which fhews a greater evolution of carbonic acid when oxygen is refpired, is totally adverfe to thofe obtained by Mr. Davy, and already mentioned. We do not therefore feel authorifed in determining whether, in general, an increafe in the quantity of oxygen employed augments the carbonic acid evolved, or whether the proportion of the latter depends on the condition of the refpiratory organs, or variations in the exercife of their functions.

If it fhould be allowed, as the greateft number of inveftigations on the fubject tends to prove, that the carbonic acid formed in refpiration be lefs in bulk than the oxygen gas, which difappears, yet the weight of the compound is increafed by the addition of carbon, derived from the animal fyftem. Lavoifier and Seguin eftimated the weight of oxygen gas confumed by a man in 24 hours, at 15661.66 grains; and that of carbonic acid produced in the fame fpace of time, at 17720.89 grains; the carbon conftituting $\frac{1}{8.6}$th of the weight of the acid formed. In the experiments of Mr. Davy, the volume of oxygen gas that difappeared every minute was 31.6 cubic inches, and that of carbonic acid produced 26.6 inches. But one cubic inch of oxygen gas weighs 0.3474 of a grain, and therefore 31.6 cubic inches will weigh 10.97784 grains: again, one cubic inch of carbonic acid weighs 0.476 of a grain, and therefore 26.6 cubic inches will weigh 12.4222 grains. From thefe facts it would feem, that the proportion of carbon in the carbonic acid of refpiration is much lefs than that which forms the fame acid in combuftion. For 100 parts of carbonic acid, formed by burning the diamond, contain, according to the very accurate refearches of Allen and Pepys (Phil. Tranf. 1807) 20.72 or 28.81 of carbon: and the proportion of carbon in 100 parts of acid is 28.77, when it is formed from charcoal and oxygen. (Murray's Chemiftry, ed. 3. v. 2. p. 487.) But there are fome points of the fubject requiring the elucidation of further refearches.

Alteration in the Bulk of the refpired Air.—On no point of the refpiratory procefs are the recorded refults of different inquiries more at variance with each other, than about the queftion of the change in volume of the air, and the amount of that change. At firft, it was generally believed, that the refpired air undergoes fome lofs; and this opinion maintained its ground until very lately, although experiments were publifhed, in which no fuch lofs was obferved. The moft accurate modern refearches are much in favour of the opinion, that the bulk of the atmofphere is not affected by breathing; and this view of the fubject is the moft generally entertained in the prefent day. Some think, that, although the volume of the refpired air is not affected in ordinary natural breathing, it may be altered under particular circumftances. The determination of the queftion concerning the volume of the air, is clofely connected with another refpecting its abforption by the blood. We fhall detail the facts and arguments on both fides, and point out that which has the moft numerous and ftrong proofs in its favour.

The diminution of bulk was early noticed by Boyle, who eftimated it at about $\frac{1}{30}$th of the air employed. Mayow, whofe genius enabled him to anticipate fo many important difcoveries of modern chemiftry, confined an animal in a glafs veffel inverted over water, and, by the aid of a fyphon, brought the water on the infide of the veffel to a level with that on the outfide. Having then marked the height of the water by pieces of paper affixed to the fide of the veffel, he obferved its gradual rife as the animal continued to breathe; and then, comparing the fpace occupied by the air at the commencement of the experiment, with that which it poffeffed when the animal ceafed to breathe, he found that it was reduced about $\frac{1}{14}$th part of its bulk. (Tractat. Quinque, p. 104.) In the experiments of Dr. Hales, the degree of diminution varied from $\frac{1}{13}$th to $\frac{1}{30}$th of the air employed. Statical Effays, v. 1. p. 230. v. 2. p. 320.

Lavoifier, in the firft memoir which he publifhed upon refpiration, afcertained the degree of diminution with more accuracy, and ftated, that air, when rendered unfit to fupport life, was reduced $\frac{1}{60}$th in bulk. (Mem. de l'Acad. 1777.) The experiments of Dr. Goodwyn afforded the fame refult.

The volume of air, taken into the lungs at a fingle infpiration, contained,

Phlogifticated air - - - - -	80
Dephlogifticated air - - - -	18
Fixed air - - - - - - -	2
	100

The volume of air, expelled from the lungs at the next fucceeding expiration, contained,

Phlogifticated air - - - - -	80
Dephlogifticated air - - - -	5
Fixed air - - - - - - -	13
	98

Connection of Life, &c. p. 51.

In the account which Lavoifier gives of the firft experiment upon the guinea pig, he found the diminution to amount to $\frac{1}{31}$ of the bulk of the air employed (Mem. de l'Acad. 1780, p. 401.); and in the fecond fet of experiments, the diminution was found to be $\frac{1}{32}$d part (Annales de Chimie, tom. v. p. 261.); the greater abforption, in thefe cafes, probably depending upon the greater purity of the air employed. In the experiments performed by Lavoifier, in conjunction with Seguin, upon the refpiration of man, though in other refpects fo remarkable for their accuracy, there is no mention made of this circumftance, nor is it noticed by La Place, in his account of the experiments in which Lavoifier was engaged, immediately previous to his execution. In thefe inftances we cannot determine whether Lavoifier conceived that no diminution actually took place, or whether he only neglected to notice it.

The general fact of the diminution of bulk in refpired air, has been fince confirmed by Mr. Davy, though the exact degree of abforption varied fo much in his different experiments, that it is difficult from them to fix upon a quantity which may indicate the ordinary amount of this diminution. In the confideration of this queftion, as in the preceding one refpecting the confumption of oxygen, and the production of carbonic acid, there are two diftinct objects of inquiry. We may examine the degree of diminution produced in a given quantity of air, in which an animal has been confined, until it is no longer fit for fupporting refpiration; and in the fecond place, we have to afcertain the amount of the diminution which takes place in air, that has only once paffed through the lungs, as is the cafe in the procefs of ordinary refpiration. The firft of thefe points only was examined by Lavoifier. Mr. Davy has made experiments upon both. In air which had only once paffed through the lungs, he found the diminution in different

trials

trials to vary from $\frac{1}{70}$th to $\frac{1}{100}$th: when he received the ſame air repeatedly into the lungs, it was found to be diminiſhed as much as $\frac{1}{18}$th of its original bulk. (Reſearches, p. 431—435.) The former experiments, however, alone indicate the effects of natural reſpiration, and taking an average of their reſults, the amount of the diminution will be about $\frac{1}{80}$th part of the whole air received into the lungs.

Mr. Murray of Edinburgh made ſome experiments on the alterations produced in the air by natural reſpiration, from which he *calculates* (for the quantity of air inſpired was not *meaſured*) that there is a loſs of 6 cubic inches in 265. Syſtem of Chemiſtry, vol. iv. p. 493, 494.

Meſſrs. Allen and Pepys, whoſe experiments we ſhall preſently allude to, as affording the ſtrongeſt arguments againſt a change of volume in the reſpired air, in natural breathing, met with a different reſult, when the circumſtances of the experiment were changed. In their fourteenth experiment, 300 cubic inches of atmoſpheric air were, in the ſpace of three minutes, paſſed eight or ten times through the lungs, until reſpiration became extremely laborious, and the operator was compelled to deſiſt. On analyſing the reſpired air, it was found to contain, in 100 parts, only 5.5 oxygen, 9.5 carbonic acid, and 85 parts of nitrogen gas. In the fifteenth experiment, which occupied alſo about three minutes, until the operator became quite inſenſible, the ſame quantity of air was employed, and afforded, by analyſis, nearly the ſame reſults; for it contained, in 100 parts, 4 of oxygen, 10 of carbonic acid, and 86 of nitrogen. In the former experiment we obſerve, therefore, an increaſe of 6 parts of nitrogen, and a loſs of 6 parts of oxygen; and in the latter, the oxygen had loſt 7 from 21, and the nitrogen had gained 7 upon 29. (Phil. Tranſ. 1808, p. 260.) Hence it is inferred, that when, as in theſe experiments, reſpiration is attended with diſtreſſing circumſtances, there is reaſon to conclude that a portion of oxygen is abſorbed. Ibid. p. 280.

In ſome experiments on the reſpiration of rabbits and of guinea pigs, Mr. Berthollet found that the bulk of acid gas produced did not quite equal that of the oxygen which diſappeared; ſo that the loſs of oxygen appeared to vary from 1.07 to 4.09 *per cent.*

We proceed to ſtate the reſult of thoſe inquiries, in which the volume of the air has been found not to undergo diminution in the act of breathing. Among the earlieſt experiments of Dr. Prieſtley on reſpiration is one, in which he confined a mouſe in a jar containing a given quantity of air, which was inverted over mercury. The animal was ſuffered to remain two or three days after he had died, in which time there was no ſenſible diminution of the air; but on paſſing lime-water into the jar, the air was diminiſhed $\frac{1}{23}$th part of its bulk; and when, in a ſubſequent experiment, the reſidual air was agitated in water, it was reduced between one-fifth and one-ſixth of the whole. Obſ. on Air, vol. v. p. 112, et ſeq.

Dr. Crawford found, alſo, that when the experiment was made over mercury, the diminution was not ſenſible; but that, if water of potaſſa was added to the reſidual air, it became mild, and the air was diminiſhed in the ſame degree as if the experiment had been made over water, or nearly one-fifth of its bulk. (On Animal Heat, p. 146.) The variations in theſe reſults, compared with thoſe before enumerated, ariſe, no doubt, from the more or leſs complete attraction of the carbonic acid by the fluids, over which the experiments were made; and, from the whole of them, we may collect, that when mercury is employed, which has no attraction for carbonic acid, the diminution is hardly ſenſible; but that, when this acid is completely abſtracted by an alkaline fluid, the loſs of bulk amounts nearly to one-fifth of the whole air employed. This inference correſponds very exactly with what occurs in vegetation, and in the reſpiration of the inferior animals.

In the year 1806, Mr. Dalton's attention was directed to this ſubject, and he ſatisfied himſelf, by numerous experiments, that the bulk of carbonic acid, formed in reſpiration, was exactly equal to that of the oxygen gas conſumed. On repeating theſe experiments, Dr. Thomſon obtained, in ſome caſes, nearly the ſame reſults; but, upon the whole, the bulk of oxygen that diſappeared was ſomewhat greater than that of the carbonic acid formed. The difference, however, varied conſiderably, and kept pace with the diminution in the whole bulk of air; whence he conſiders it to ariſe from the abſtraction of a part of the air by ſome other way than by reſpiration: and if this be allowed for, he believes the bulk of acid produced to be preciſely equal to that of oxygen gas loſt. Hence, ſays he, this oxygen muſt be changed into carbonic acid in the lungs; for oxygen gas, when changed into carbonic acid, does not ſenſibly alter its bulk. Syſtem of Chemiſtry, 3d edition. vol. v. p. 736, and 774.

Theſe concluſions have been completely confirmed by the very accurate experiments, already noticed, of Allen and Pepys. There was a loſs of 23 cubic inches only in 3460 breathed once, at 58 reſpirations, which occupied 11 minutes. In another experiment, 9890 cubic inches, of which the breathing occupied $24\frac{1}{2}$ minutes, loſt only 18. In ſubſequent experiments on the reſpiration of a guinea pig, theſe chemiſts found, that when 310 cubic inches of atmoſpheric air were breathed for 25 minutes by this animal, its volume experienced no variation whatever; and the portion of its oxygen, which diſappeared, was replaced by an equal bulk of carbonic acid. Theſe reſults were particularly ſatisfactory in their tendency to eſtabliſh the point, that the air undergoes no diminution; becauſe the time which they occupied was more conſiderable, and the chance of error, therefore, diminiſhed. The third trial with the guinea pig occupied one hour: the bulk of the atmoſpheric air, before the experiment, was 1060 cubic inches; after the experiment, 1061; the carbonic acid formed 53 cubic inches; the carbonic acid *per* minute, .88 of a cubic inch. (Phil. Tranſ. 1809, p. 414.) Wherefore they juſtly conclude, that when atmoſpheric air alone is reſpired, no other change is produced in it than the ſubſtitution of a certain portion of carbonic acid gas for an equal volume of oxygen.

The reſults of all the trials made by theſe gentlemen were not uniform, and the deficiency was ſometimes greater than what has been ſtated. The deficiency varied from 4 to 62 cubic inches in ten experiments; in each of which, between 3 and 4000 cubic inches of air were breathed once, the time employed being 10 or 11 minutes in each experiment. They conſider that the deficiency principally ariſes from the laſt expiration being made into a gaſometer, and conſequently meeting with more reſiſtance; ſo that the lungs are leſs completely evacuated than in the expiration into the open air, with which the experiment commenced.

The difficulty, which theſe gentlemen allude to, of bringing the lungs to the ſame ſtate exactly at the end as they were in at the beginning of the experiment, is evinced by the reſult of their thirteenth trial, which alſo affords a ſtrong argument againſt the diminution of bulk, which has hitherto been almoſt generally aſſumed as a reſult of the reſpiratory proceſs. In $5\frac{1}{2}$ minutes, 3300 cubic inches were inſpired, and 3311 expired; thus exhibiting an increaſe of 11.

Amid this conflict of authorities, we have no difficulty in in declaring it, as our decided opinion, that the experiments leaſt liable to error, moſt carefully performed, and therefore deſerving our greateſt confidence, are thoſe which contradict the notion of an abſorption of oxygen.

"In caſes," ſays Mr. Ellis, "where ſo many cauſes concur to render the apparent bulk of acid leſs than it ought to be, and leſs than that of the oxygen loſt, it is ſurely more reaſonable to give greater credit to thoſe reſults, which indicate an equality of volume between theſe gaſes, than to thoſe which declare a difference; ſince the former not only go with the latter to the fulleſt extent; but, purſuing the ſame track, have actually gone beyond them, and thereby reached a point, which the others have been unable to gain. In fact, to prefer thoſe experiments, which indicate a difference, to thoſe which prove an equality of volume, would be not only to halt in our progreſs, but to make a retrograde movement, and thus to ſuffer a negative inference to outweigh a poſitive proof." Further Inquiry, p. 279.

By the experiments of Meſſrs. Allen and Pepys, we have ſeen it proved, that when a guinea pig breathes a given quantity of air in a natural manner, no variation whatever was obſerved in the bulk of that air; and that in man, in whom many cauſes, not affecting the lower animals, contribute to produce error, when the reſpiration was nearly natural, the general average of the deficiency, in the total amount of common air inſpired, was only about ſix parts in 1000, and in one inſtance conſiderably leſs than two. The ſmallneſs of this deficiency, ſay theſe chemiſts, ſurpriſed us very much; and it probably ariſes from the difficulty, or, as they elſewhere term it, the impoſſibility of always bringing the lungs to the ſame ſtate after forcible expiration.

Under other circumſtances, as in the experiment recited above, of reſpiration continued until the operator became inſenſible, theſe gentlemen conceive that oxygen is abſorbed. To this inference, ſays Mr. Ellis, as far as it regards what is here called an abſorption of oxygen, we muſt beg leave to object. That the united volumes of oxygen and carbonic acid expired were leſs than the total volume of oxygen inſpired, we readily grant; but we deny that this fact affords any adequate proof of an abſorption of this latter gas. To the chemiſt, indeed, the mere fact of the diſappearance of a portion of oxygen may ſupply ſufficient evidence of its abſorption, in the ſenſe in which he may chooſe to employ that term; but the phyſiologiſt farther requires to know, by what organs or veſſels it is removed, in what courſe it is conveyed, and what uſes it is deſtined to ſerve. On none of theſe points, however, does he gain any information; and all the anatomical knowledge which he poſſeſſes of the ſtructure of the lungs, and of the properties of the living abſorbent ſyſtem, is adverſe to ſuch a doctrine. Should he apply to the chemiſt for a ſolution of his difficulties, he is told that oxygen does not chemically combine with other bodies, unleſs it be brought into actual contact with them; and he knows, that, in the preſent caſe, this contact is impoſſible, becauſe the membranes, both of the air-cells and blood-veſſels, are interpoſed between the air and the blood in the lungs. Even if, contrary to all experience and analogy, he were to concede to the chemiſt the exiſtence of pores or other paſſages in the cells and blood-veſſels, through which this oxygen might be attracted and combine with the blood, he is equally embarraſſed to diſcover the reaſon or mode in which it is again ſo ſpeedily expelled, or what uſeful purpoſe it can ſerve, ſince no portion of it is permanently retained. The ſcience of chemiſtry furniſhes no example of ſimilar operations,—of fluids which attract gaſes and combine them, ſo as to reduce their elaſticity, and then, without any apparent change of condition or circumſtances, almoſt inſtantly diſcharge them in a new and elaſtic form.

If, farther, we compare the reſults of the two ſeries of experiments made by Meſſrs. Allen and Pepys, the difficulties, in a phyſiological point of view, greatly accumulate upon us. For, if an *abſorption* of oxygen really take place in the lungs, how does it happen, that, in the firſt thirteen experiments, made with ſeveral thouſand cubic inches of air, and which occupied from ten to twenty-four minutes of time, a very ſmall loſs in the whole bulk of air, and not the ſmalleſt in its proportion of oxygen, occurred; while, in two other experiments, made with only 300 inches of air, and continued only for three minutes of time, a great deficiency in the whole bulk of air, and a loſs of one-third of its oxygen, took place. In all theſe experiments, except the twelfth, in which, inſtead of loſs, there was actually an increaſe of eleven cubic inches upon the bulk of air reſpired (Phil. Tranſ. 1808, p. 256.), the ſame perſon appears to have breathed, and the air was of ſimilar compoſition. Conſequently, the cauſe of variation in the reſult is to be ſought, not in any difference in the animal organs, or in the original compoſition of the air, but, probably, in ſome circumſtances of diſſimilarity, which accompanied the progreſs of the experiment.

Now the bare ſtatement of facts points out a great diſſimilarity, not only in the chemical reſults, but in the circumſtances accompanying the experiments, and in the effects which they produced in the ſyſtem. For in the firſt thirteen experiments, which occupied from ten to twenty-four minutes, and in which no loſs of oxygen occurred, the air was only *once* paſſed through the lungs, the breathing was nearly natural, the operator ſcarcely fatigued, and his pulſe not raiſed more than about one beat in a minute. (Ibid. 253.) But in the two experiments in which oxygen is ſaid to be abſorbed, the ſame air was paſſed *eight or ten times* through the lungs; and, in leſs than a minute, the operator found himſelf obliged to take deeper and deeper inſpirations. At laſt, the efforts to take in air became very ſtrong and ſudden, with a great ſenſe of oppreſſion and ſuffocation in the cheſt, indiſtinct viſion, buzz in the ears, loſs of recollection, and, at the end of three minutes, perfect inſenſibility. (Ibid. 260—262.) This difference in the effects produced in the ſyſtem, we do not heſitate to aſcribe to a difference in the *compoſition* of the air, which, in the firſt experiments, was reſpired in a natural ſtate, but, in the two laſt, by repeated breathing, was rendered more and more unfit to carry on reſpiration, until, at length, its power of ſupporting that function altogether ceaſed.

But becauſe under circumſtances, in which the mental and animal powers were in complete abeyance, the reſpiratory organs were not able to make ſo complete an expulſion of the inſpired air as they effect in their natural ſtate of health and vigour, are we, therefore, entitled at once to conclude, that all the air which was not expelled was really *abſorbed*? Setting aſide the anatomical difficulties in the caſe, let us, for a moment, look only to the chemical conſequences, to which ſuch a concluſion would conduct us. If the mere diſappearance of any gas, received into the lungs, be ſufficient evidence of its abſorption, then every gas, which is not returned, muſt be held to be abſorbed. Are we then prepared to admit that hydrogen and nitrogen gaſes are abſorbed by the blood? for, when their reſpiration is carried to its full extent, they, too, equally diſappear. This ſuppoſed abſorption, however, cannot proceed from the operation of chemical attraction, for little or no affinity ſubſiſts between theſe gaſes and the blood. Neither can it ariſe from the operation of the living ſyſtem; for it occurs only when

when the living powers are about to ceafe. To us there appears but one way of efcaping from thefe manifold difficulties, which is fimply to conclude, that the infpired air, which is not returned, is retained in the cells of the lungs. Such a fuppofition diffipates at once all anatomical and chemical difficulties, and explains why no air difappears in natural refpiration, when the expiratory powers are in full vigour and able to expel it, and why its difappearance increafes in proportion as the actions of thefe powers decline and ceafe.

It is, however, worthy of remark, that, in thefe laft experiments, not only was there a diminution in the whole bulk of air, but its relative proportions likewife varied; for, in 100 parts, the oxygen and carbonic acid amounted together only to about two-thirds of the ufual quantity of oxygen, and the deficiency was fupplied by a fuperabundance of nitrogen gas. We are not prepared to fay why, in this very embarraffed ftate of the refpiratory function, the relative proportions of the expired air fhould thus vary; but the fact proves only the retention of oxygen in the lungs, but not its abforption by the blood. Should it even be maintained that oxygen was abforbed, becaufe, in thefe two experiments, a portion of it difappeared, then, by the fame mode of reafoning, we muft alfo contend, that, in the thirteen preceding experiments, no abforption of oxygen took place, becaufe no part of it was retained; and as thefe laft experiments alone come near to the natural exercife of this function, they authorife us to conclude, that fuch fuppofed abforption of oxygen conftitutes no neceffary part of healthy refpiration. In truth, in fome inftances where a mixture of oxygen and hydrogen gafes was refpired, the oxygen and carbonic acid in the expired air uniformly exceeded, by one *per cent.* the total oxygen infpired (Phil. Tranf. 1809, p. 425.); from which it may be inferred, that thefe variations in the proportions of the expired air proceed entirely from accidental caufes, and are totally independent of any abforbent function in the lungs. Further Inquiry, v. 2. ch. 4.

If we are correct in reprefenting that the air undergoes no diminution of volume in breathing, it will follow neceffarily that no part of it can be abforbed in the lungs. This notion of abforption is not only at variance with the refults of the moft accurate direct experiments, but it is alfo repugnant to our knowledge of the ftructure of the lungs. The finenefs of the abforbing veffels, the mucus perpetually fmearing the furface of the cells, the elaftic nature of air itfelf, fo that it neither penetrates moift paper, cloth, nor fkin—all demonftrate that no air gets into the blood by this route. If, indeed, air were taken up by the abforbents, it muft pafs to the right fide of the heart, and change the colour of the blood there, which does not happen.

But if, either by the function of abforption, or by the operation of chemical affinity, air did enter into the blood, we may furely with reafon demand fome proof of its prefence; yet, fays Haller, "Nulla unquam in vivo calido animali bulla aëris in fanguine vifa eft." (Primæ Lin. f. 306.) This opinion is confirmed by the direct experiments of Dr. Darwin; for having inclofed a portion of the jugular vein of a fheep between two ligatures, it was cut out, ftripped of its adhering cellular membrane, and then thrown into a glafs of water of temperature 100°, ftanding under the receiver of an air-pump. It at once funk to the bottom, and did not rife when the air was exhaufted; nor, when afterwards taken out, wiped dry, and laid on the floor of the receiver, did it exhibit any fwelling under the exhauftion of the veffel. The experiment was repeated with a fimilar refult on a portion of the vena cava of a pig. Phil. Tranf. v. lxiv. p. 345.

Neither do the effects refulting from the admixture of aëriform fluids with the blood, favour the notion of the entrance of air into that fluid. "Animal, cui aër in fanguinem inflatur," fays Haller, "perit certo et velociter; neque quidquam fatis certi eft in fanguinis venarum pulmonalium aucto rubore." (Loc. cit.) This affertion is confirmed likewife by direct experiment. When Dr. Girtanner injected oxygen gas into the jugular vein of a dog, he cried dreadfully, breathed quick, and died in three minutes; when nitrogen gas was thrown in, death happened in 20 feconds. (Memoirs on Irritability, pp. 221. 223.) Air, fays Bichat, thrown into the vafcular fyftem, quickly brings on agitation, convulfions, and death. (Récherches fur la Vie et la Mort, p. 179.) By forcing air through the windpipe into the lungs with a fyringe, and confining it there, he has made it to enter into the blood-veffels, which immediately brings on agitation and exertion in the animal; and if an artery in the leg or foot be now opened, the blood will fpring out frothy, and full of bubbles of air. If hydrogen gas has been ufed, the bubbles may be inflamed; and when this frothy blood has flowed 30 feconds, the actions of life ceafe, and cannot again be reftored, even although frefh air be fupplied. Ibid. 303. Inquiry, § 102, 103.

If, then, no proof exift of the paffage of air into the blood by the ordinary courfe of the abforbent veffels, the only other mode of effecting this purpofe that has been hitherto fuggefted, is the power of *chemical affinity*. What then are the chemical affinities fubfifting between venal blood and atmofpheric air? About the middle of the 17th century, Dr. Lower obferved, that the upper furface of venal blood, received into a veffel, acquired a fcarlet colour by expofure to the air; that if this furface was removed, the fubjacent one was foon changed to the fame colour; that if the cake of blood, after being allowed to fettle in the veffel, was inverted, its exterior and upper furface fpeedily alfo affumed a florid hue; and, laftly, that if venal blood was fhaken in a veffel, fo that the air thoroughly intermixed with it, it became entirely florid. (De Corde, p. 178.) Thefe opinions were afterwards held by Sig. Fracaffati and Dr. Slare, the latter of whom obferves, that the blood thrown up by a rupture of the capillary veffels of the lungs, is frothy and of a fcarlet colour; the firft of which effects he attributes to the intermixture of air, and the latter to its tinging power. (Lowthorpe's Abridg. Phil. Tranf. v. iii. p. 235.) Mr. Hewfon employed fimilar arguments to prove, that the florid colour, acquired by venal blood on expofure, was produced by the contact of the air; and, by injecting air into the jugular vein of a rabbit, he found that it there alfo rendered the blood florid. (Hewfon on the Blood, p. 9.) M. Cigna not only confirmed the foregoing facts, but proved alfo that the change of colour in this fluid did not take place when the blood was covered with oil or placed *in vacuo*; and Dr. Prieftley afcertained that not only by common air, but more efpecially by oxygen gas, this florid colour was produced on the black craffamentum of blood. On Air, v. iii. p. 66.

In effecting thefe remarkable alterations in the colour of the blood, the air itfelf, at the fame time, fuffers material changes. Dr. Prieftley found, that in twenty-four hours oxygen gas was fo far depraved by being in contact with venal blood, that one meafure of it and two of nitrous gas occupied the fpace of a meafure and a half, whereas, at the beginning of the experiment, they occupied the fpace of no more than half a meafure. (Loc. cit. p. 75.) Dr. Goodwyn

wyn confined venal blood under a jar of oxygen gas inverted in mercury, and repeatedly obferved that the change of colour was always very fudden, and, after feveral minutes, the mercury afcended two or three lines; from which he concluded that a fmall portion of the air had difappeared. (Effay, p. 61.) The precife change, however, which the air underwent, feems firft to have been obferved by Dr. Girtanner, who placed fix ounces of venal blood in a jar of oxygen gas inverted in mercury; the blood prefently affumed a florid colour; the air was fomewhat diminifhed in bulk, and contained a portion of carbonic acid, which was attracted by lime-water. (Beddoes' Obf. on Calculus, &c. p. 219.) Dr. Boftock obferves alfo, that a diminution of oxygen and production of carbonic acid take place when a piece of craffamentum is placed in a jar filled with oxygen gas. (On Refpiration, p. 227.) The fame production of carbonic acid occurs when blood is placed in contact with atmofpheric air. A quantity of this fluid was received into a cup, and confined in a jar of air inverted in water, a glafs of lime-water having been previoufly placed in the cup. The internal furface of the jar was foon bedewed with moifture, and a pellicle began to form on the lime-water, which, in a few hours, was increafed to a thick cruft of carbonate of lime. The craffamentum was then removed, and a frefh glafs of lime-water was placed in the ferum, which, in thirty-fix hours, had acquired a cruft like the former, and the water had rifen confiderably into the jar. In another experiment, where the ferum was placed for twenty-four hours in a jar of air inverted in mercury, the refidual air rendered lime-water milky, and the remainder had loft a part of its oxygen. A fimilar production of carbonic acid feems to have occurred, when, with a fmall diminution of the gas, a flight change of colour was produced on venal blood by placing it in contact with nitrous oxyd, in the experiments of Mr. Davy; for when a folution of ftrontian was admitted to the oxyd, it became flightly clouded, and, with the diminution of bulk that followed, minute portions of carbonic acid and nitrogen gas were produced. (Refearches, pp. 377. 380. 387.) Hence then we learn, that when venal blood is expofed to the contact of atmofpheric air, of oxygen gas, or of nitrous oxyd, it prefently affumes a florid colour, and, at the fame time, the volume of air is fomewhat diminifhed, and a portion of carbonic acid is produced.

Does then the carbonic acid, which is here met with, proceed ready formed from the blood, or is it in part formed by the decompofition of the air? No one has yet proved that any aëriform fluid, much lefs that carbonic acid, exifts naturally in the blood; and if this be true, no fuch aërial acid can be expected to iffue from it. The carbonic acid alfo, is not formed by blood when it is confined in nitrogen gas; neither does the colour of the blood, in that cafe, undergo any fenfible change; but this acid is formed by blood, either in oxygen gas, in nitrous oxyd, or in atmofpheric air, all of which are deteriorated thereby; whence it follows, that without the prefence of oxygen gas, the blood is unable to form carbonic acid, and that this acid, therefore, is, in part, formed out of that gas. If the oxygen gas that difappears do not contribute to form the carbonic acid that is produced, in what other manner can its lofs be accounted for? or from what other fource than the oxygen gas of the air, in contact with the blood, can that ingredient of the acid be derived? Thofe who fuppofe the carbonic acid to be furnifhed by the blood, independent of the air employed, muft likewife fuppofe that the nitrogen gas is furnifhed by it alfo; for the experiments of Mr. Davy teach us, that a portion of that gas, as well as of carbonic acid, is always prefent when nitrous oxyd is decompofed, which renders it probable that the fame thing likewife occurs when air is changed by venal blood. But in what manner the blood fhould be able to furnifh nitrogen gas, it is not eafy to conceive, fince no affinity exifts between that gas and venal blood. (Davy's Refearches, p. 375.) We infer, therefore, from thefe facts, that atmofpheric air is decompofed by being placed in contact with venal blood, its oxygenous portion being in part converted into carbonic acid, and a quantity of its nitrogen being, in confequence, left free.

But, fuppofing the air to be thus decompofed by the blood, it ftill remains a queftion, whether it has been firft attracted by that fluid, then decompofed, and afterwards in part expelled; or, whether the decompofition has been effected without fuch previous attraction and intermixture of air. The only evidence of this fuppofed attraction feems to be the fmall diminution of bulk, which the air in all cafes fuffers; but this cannot be confidered as a proof of the attraction of the air; for it is a neceffary confequence of that converfion of oxygen gas into carbonic acid, which has been fhewn to take place, when thefe fubftances are brought into contact. Even granting to the blood this power of attracting air, or its oxygenous portion, it is not eafy to conceive, why it fhould fo readily lofe it, and again give out this air in the form of carbonic acid. No change of quality in the blood, nor any variation of temperature, can have taken place fufficient to alter fo rapidly its affinity for thefe fubftances: and it cannot proceed from a want of affinity between the blood and the carbonic acid that is formed; for that acid fuffers a greater diminution, either than oxygen gas or atmofpheric air, by being placed in contact with blood. We incline, therefore, to the opinion, that neither the air nor its oxygen gas is attracted by, and diffufed through the blood, as happens with feveral gafes when placed in contact with certain fluids: but that the air is decompofed, and its oxygen gas changed into carbonic acid, without entering into the fubftance of that fluid.

But, for the formation of this acid, the blood muft fupply carbon, fince no other fubftance was prefent from which it could be derived: and it is well known alfo, that carbon enters largely into the compofition of that fluid; and our experiments prove, that it exifts as well in the ferous as in the more folid parts. By fome it may be objected, that becaufe carbonic acid is formed directly by the combuftion of charcoal, it cannot be produced at fo low a temperature as exifts in thefe experiments. To this we can reply only by an appeal to the general facts exhibited through the whole courfe of our enquiry, by which it appears, that both by the living functions of vegetables and animals, and by the decompofition of animal and vegetable matter, this acid is in like manner formed at temperatures equally low. Even thofe, who confider this acid to have proceeded ready formed from the blood, cannot attribute its production to the operation of heat; for in the animal body, the temperature of the blood feldom exceeds 100°—a degree of heat incompetent to form carbonic acid by any procefs analogous to combuftion. The combination of many bodies is, indeed, greatly accelerated by being expofed to very high temperatures; but this furely does not fet afide the fact of their fpontaneous union at temperatures much more low. From this review of the effects, which take place between the blood and air, we conclude, that the chemical phenomena, which arife when the fubftances are placed in contact, do not prove an attraction and diffusion of air through the blood; but shew only that a reciprocal action takes place, by which a new product is formed: no inference, therefore, in favour of an attraction of air by the blood in the lungs, can be drawn from the reciprocal action which they exert on each other out of the body. Inquiry, § 96—100.

It is, farther, an objection to this supposed operation of oxygen, that in the lungs the blood and air do not come into contact, and therefore although the combination of oxygen with that fluid might be conceived to happen, when they are placed together out of the body, yet the intervention of organised membranes may be supposed to prevent such an union in the living system. In the ordinary operations of chemistry, such an interposition of animal substance would be considered sufficient to vitiate the result of any similar experiment in which it was employed; but in the application of this science to the living body, neither membranes nor blood-vessels are conceived to oppose any obstacle to the exertion of chemical action, or, in the smallest degree, to affect its result. In support of this supposed operation of oxygen on the blood, some experiments of Dr. Priestley have been appealed to, as affording decisive evidence that this substance has the power of penetrating a compact membranous body, and may, consequently, penetrate the cells and blood-vessels of the lungs. The importance, which has been attached to these experiments, in all the late hypotheses which have been proposed to explain the function of respiration, renders it necessary for us to examine them with some minuteness, in order to discover the true relation which they bear to the present question.

Dr. Priestley, who, as we shall hereafter see, supposed that venal blood became red by imparting its phlogiston to the air, knew well that the blood in the lungs was separated from the air by a membranous substance, which, however, according to Dr. Hales, does not in thickness exceed the $\frac{1}{1000}$th part of an inch. To ascertain the effect of this circumstance, he put some black blood into a bladder moistened with a little serum, and then tying the bladder very close, he hung it in a free exposure to the air. The next day, all the lower surface of the blood, which had been separated from the air by the intervention of the bladder, had acquired a coating of a florid red colour, as thick, it appeared, as it would have acquired, if it had been immediately exposed to the open air; so that this membrane had been no impediment to the action of the air on the blood. This experiment was repeated, without previously moistening the bladder, and with the very same result. Obs. on Air, vol. iii. p. 369.

But although in these experiments the blood was rendered red by the agency of the air, yet we are not entitled to conclude, that this redness was produced by the combination of its oxygen, unless we can shew, not only that this substance comes into contact with the blood, but is likewise capable of changing it to a red colour. Dr. Priestley himself, who believed the blood to become red by the loss of phlogiston, could draw no such conclusion; and it is not a little remarkable that this philosopher, who had before so well observed the reciprocal effects produced in the air, when it thus changed the colour of the blood (loc. cit. p. 336.), should in these experiments have entirely overlooked them. It is still more remarkable, since these experiments have drawn so much attention, and seem now to be the chief or only remaining evidence urged in support of the hypothesis of oxygenation, that some attempt has not been made to inquire farther into the actual circumstances which attend them. It is this examination which we now propose to make, in the hope, that if it do not lead us to a knowledge of the true cause of this phenomenon, it may at least serve to shew to what it is not to be ascribed.

With this view, we procured a quantity of black blood, and putting it into a sheep's bladder, suspended it from the top of a jar containing about 100 cubic inches of atmospheric air. The jar was inverted in a saucer containing mercury, and within it a small cup of solution of potassa was likewise placed. The blood, in a short time, assumed a florid hue, and a dimness extended over the inside of the jar. By the next day, the mercury in the saucer had risen $\frac{3}{10}$ths of an inch into the jar, and it continued to rise several days; so that by the fifth day it had reached nearly to an inch in height. The jar was then raised, and diluted acid being poured upon the alkaline solution, disengaged from it a large quantity of carbonic acid gas. By this experiment, therefore, we are taught, that, when black blood assumes a red colour by being thus placed in a moistened bladder, and exposed to atmospheric air, the air itself, at the same time, undergoes a change; for its volume is diminished, and carbonic acid is produced.

To ascertain these facts with greater precision, we put another quantity of black blood into a small bladder, and suspended it, as before, from the top of a small jar inverted in mercury, and which contained 18.3 cubic inches of atmospheric air. Under this jar also a small cup of solution of potassa was placed. The blood, as before, was soon reddened, and the jar became dim. In two days, the mercury had risen nearly half an inch into the jar, and by the close of the fourth day, it stood seven-eighths of an inch high, where it remained for some time quite stationary. On analysing the residual air, it was found to suffer no change, either from agitation with lime-water, or by being exposed to the contact of phosphorus; so that, though all the oxygen had disappeared, no carbonic acid was present, but that gas was entirely attracted by the water of potassa employed.

The capacity of the jar, in the above experiment, has been stated to be equal to 18.3 cubic inches; and the bladder, with its contents, together with the cup and solution, we found to occupy a space equal to 5.2, which reduces the actual bulk of air, employed in the experiment, to 13.1 cubic inches. The mercury which in consequence of the attraction of the carbonic acid had risen seven-eighths of an inch into the jar, occupied a space equal to three cubic inches; so that of the 13.1 inches of air originally employed, three had disappeared, and $\frac{3}{13.1} = \frac{1}{4.37}$, or a portion of the air, was thus converted into carbonic acid, which comes very near to the proportion of oxygen gas which the atmosphere is known to contain. Hence we infer, that, in this experiment, all the oxygen gas that disappeared was converted into carbonic acid; and consequently we deny that any oxygen penetrated the bladder, in order to combine with the blood.

As thus it is denied that the blood, in these experiments, received any ponderable matter from the air, so likewise it will appear, from the facts which follow, that the air receives no such matter from the blood. We filled bladders with water, and suspended them in jars of atmospheric air, in the manner described above; and found that the oxygen gas of this air was converted into carbonic acid, in the same manner as when the bladders were filled with blood: and if the experiment was continued a sufficient length of time, the whole of the oxygen gas was, in like manner, made to disappear. The same effects followed from the introduction of of moiſtened empty bladders; and, indeed, it is the uſual effect produced in the air by every moiſtened animal ſubſtance. If, therefore, the moiſtened bladder be thus capable, by itſelf, of acting on the air, we are entitled to conclude that it exerts the ſame action when it is filled with blood; and as, on this ſuppoſition, the oxygen gas will unite with the carbon, furniſhed directly by the bladder, we have no ground whatever to ſuppoſe this carbon to come from the blood. Hence, therefore, when black blood is reddened by the air, through the coats of a moiſtened bladder, the air yields no oxygen to the blood, nor acquires from it any carbon; but the carbon of the bladder, by its combination with the oxygen of the air, paſſes into a ſtate of carbonic acid gas. Further Inquiry, § 581—587.

That this change in the colour of blood is always accompanied by a correſponding change in the air, may be farther inferred from other experiments of Dr. Prieſtley. He found that, when the black craſſamentum of blood was covered by ſerum or milk, it neverthelefs acquired a florid hue, on being expoſed to the air (Obſ. on Air, vol. iii. p. 370.); and Dr. Wells obſerved, that a covering of albumen, alſo, did not prevent the action of the air on the blood. (Phil. Tranſ. 1797.) Now we know that ſerum and albumen convert the oxygen gas of the air into carbonic acid; and we found by experiment, that the ſame effect was produced by milk, as probably would be the caſe with moſt of the animal fluids. Hence it is evident, that when the blood, in the experiments of Dr. Prieſtley, became florid, through ſeveral inches of ſerum, the oxygen gas muſt have been at once changed by it into carbonic acid, and could never, therefore, in the form of oxygen, be conveyed through this fluid to act on the blood.

On the other hand, Dr. Prieſtley found a thin ſtratum of water to prevent entirely this action of air on the blood. (Obſ. on Air, vol. iii. p. 370.) M. Cigna found the ſame thing to take place, when a pellicle of oil was interpoſed (ibid.); and Dr. Wells aſcribes a ſimilar effect to a ſolution of gum arabic. Theſe ſubſtances, however, act little, if at all, in changing the air; and no change of colour, therefore, takes place in the blood. That black blood ſhould have the power of attracting the oxygen of the air, through ſeveral inches of ſerum, and yet loſe this power when a thin ſtratum of water is interpoſed, ſeems ſomewhat ſurpriſing, if the intervening fluid be, in each caſe, conſidered to be equally paſſive; but proceeding on the fact, that the ſerum exerts an action on the air, which the water is incapable of effecting, a new circumſtance comes into view, and upon it the colouration of the blood may probably depend.

If, then, it appear, that the interpoſition of ſubſtances between the blood and the air neceſſarily prevents that contact, which is eſſential to the chemical union of oxygen with that fluid; if it alſo appear, that the colour of the blood is never, in ſuch caſes, changed, unleſs ſuch ſubſtances be interpoſed, as are themſelves capable of acting on the air; and if, laſtly, it be proved, that when the blood exhibits this change of colour, the air ſuffers a change, and that its oxygen, inſtead of combining with the blood, is really contained in the carbonic acid that is formed, we muſt conclude, that, whatever be the mode in which the air contributes to change the colour of the blood, it cannot be by imparting to it any portion of its ponderable matter. Conſequently, although theſe facts prove that oxygen gas poſſeſſes the power of changing the colour of the blood, as well through dead as through living animal membranes, yet they afford no evidence of the combination of oxygen with that fluid, but ſhew only the converſion of that gas into carbonic acid, preciſely in the ſame manner as this acid gas is formed, when the blood is reddened in the ordinary proceſs of reſpiration.

Even when the air and blood are brought into contact, they only exert a reciprocal action on each other, by which carbonic acid is formed, but no oxygen appears to combine with the blood. We have already given various proofs, that, when the blood is changed in colour by the agency of the air, the oxygen gas of the air diſappears, and carbonic acid is produced. Theſe facts are confirmed by the experiments of M. Berthollet, who confined recent blood in a veſſel of common air, and, at the end of twenty-four hours, the air, on analyſis, afforded nearly $\frac{4}{100}$ of carbonic acid. In two other experiments, ſimilar reſults were afforded; and in all theſe experiments, the acid gas produced was exactly equal to the volume of oxygen that diſappeared. (Mem. d'Arcueil, tom. ii. p. 462.) Unleſs, therefore, it be maintained, that the ſame oxygen can, at the ſame time, exiſt in two combinations, we muſt ſuppoſe, that, in theſe experiments, no oxygen combines with the blood; and from whatever cauſe, therefore, the red colour of the blood may proceed, we may ſafely conclude that it cannot ariſe from the combination of oxygen. Further Inquiry, § 592—595.

Mr. Ellis conſiders that the diminution in bulk, which the reſpired air undergoes, according to the reſults of moſt inveſtigations, may be accounted for by the condenſation which oxygen experiences in uniting with charcoal to form carbonic acid. Crawford eſtimated this diminution at $\frac{1}{7}$th, Lavoiſier at $\frac{1}{25}$th. But the experiments of Allen and Pepys (Phil. Tranſ. 1807), performed with a very perfect apparatus, and therefore apparently deſerving confidence, do not ſupport this notion of condenſation. When they tranſmitted repeatedly oxygen gas over ignited charcoal, ſo as to convert it into carbonic acid, the volume was the ſame at the end of the experiment as at the commencement. The reſearches of theſe chemiſts on reſpiration, publiſhed ſince the appearance of the "Inquiry," making it very probable that there is no loſs of bulk in the air reſpired, coincides with what they have proved concerning the conſtitution of carbonic acid.

Whether the azote of the inſpired air undergoes any change?—Mr. Murray has brought together all that is known on this point, and arranged it ſo clearly, that we avail ourſelves of his labours, without any further remark.

"It is laſtly to be determined, what is the influence of the nitrogen of the atmoſphere in reſpiration; and with regard to this, different concluſions have been formed. Lavoiſier, in his early experiments, conſidered the nitrogen of the atmoſpheric air as ſuffering no change in reſpiration. Mem. de l'Acad. des Sciences, 1777. Mémoires de la Société de Médecine, 1783.

Prieſtley, in the experiments already referred to, in which he breathed the ſame air repeatedly, obſerved an apparent conſumption of its nitrogen, as well as of its oxygen; but he afterwards inclined to the ſuppoſition, that the deficiency of nitrogen aroſe from the greater proportion of it in the lungs after the proceſs than before.

Mr. Davy inveſtigated this, and concluded that nitrogen is conſumed in reſpiration; a quantity diſappearing equal to about two-tenths of a cubic inch at each natural reſpiration, 13 cubic inches being the quantity of air taken into the lungs. As the number of natural inſpirations amounted in a minute to 26 or 27, it followed that, in this time, 5.2 cubic inches of nitrogen are conſumed; a reſult which was confirmed by continued reſpiration, as well as by the reſpiration of animals confined in a portion of air; though,

though, in the latter case, the quantity consumed appeared to be less. Chemical Researches, p. 434.

This absorption of nitrogen in respiration appeared to be confirmed by other experiments. It was observed by Dr. Henderson, in breathing a portion of air repeatedly from and into a gasometer. (Nicholson's Journal, vol. viii. p. 40.) And it seemed likewise to be established by the experiments of Pfaff. Nicholson's Journal, vol. xii. p. 249.

These experiments, however, are not free from fallacy, particularly those where the same quantity of air was repeatedly breathed; for, as Mr. Ellis has justly observed, (Inquiry on Vegetation, Respiration, &c. p. 114.) the respiration, as it proceeds, becomes more difficult and laborious, and is at length terminated by a feeble expiration, in consequence of which the due proportion of air is not thrown from the lungs. There appears, therefore, a diminution; and accordingly it is stated by Pfaff, that the diminution and the loss of nitrogen is always the greater, the longer the air is respired. There can be little doubt that the apparent diminution arises from this cause; and accordingly, in the experiments of Allen and Pepys, in which this source of error is avoided, there is no apparent consumption of nitrogen. The same result is stated to have been obtained in the last experiments of Lavoisier and Seguin, "there being neither any disengagement nor absorption of nitrogen gas during the respiration." (Mem. de l'Acad. des Sciences, 1789, p. 374.) From the experiments of Vauquelin, Spallanzani, and Ellis (Inquiry, &c. p. 87, 88.), it also appears that there is no sensible consumption of nitrogen, by the respiration of the lower orders of animals, while there is the usual consumption of oxygen, and formation of carbonic acid.

Messrs. Allen and Pepys, from some experiments (Phil. Trans. 1809), inferred, that there is even an evolution of nitrogen in respiration. They observed this, first, in the respiration of oxygen gas; in one experiment, where 3000 cubic inches of oxygen had passed through the lungs, 62 cubic inches of nitrogen being found in the first 260 cubic inches expired, though the gas originally contained only six cubic inches in this quantity; and in the next 562 cubic inches, 56 cubic inches were found, though this quantity, before it was respired, contained only 14; and a similar evolution of nitrogen was observed in the repeated respiration of the same quantity of oxygen, an equivalent quantity of oxygen disappearing. Much of this loss of nitrogen may, as they observe, be ascribed to the intermixture of the residual air in the lungs; but from comparing the capacity of the lungs with the quantity of nitrogen evolved, they found more of it to be evolved than could be derived from this source; and were therefore led to the conclusion, that where oxygen gas is respired, a portion of nitrogen is given off from the blood. This conclusion appeared to be confirmed by the results of experiments on a guinea pig, confined in a quantity of atmospheric air. In one experiment, at the end of an hour and twelve minutes, the increase of nitrogen in the air was more than equal to the cubic contents of the body of the animal. In the respiration of a mixture of oxygen and nitrogen gases, a similar evolution of nitrogen, and disappearance of an equivalent portion of oxygen, was observed; but not in the respiration of atmospheric air.

Three thousand four hundred and twenty cubic inches of air, consisting of 2.5 azote, and 97.5 oxygen in 100 parts, were breathed for 7′ 25″: the expired air measured 3362, therefore the deficiency was 58. The expired air was received in 13 successive portions; of which N° 1. contained, in 100 parts, 9 carbonic acid, 25 azote, 66 oxygen. N° 13. consisted of 12.5 carbonic acid, 5.5 azote, and 82 oxygen, in 100 parts. When all the thirteen were mixed, the composition was 12.0 carbonic acid, 6.5 azote, 81.5 oxygen. The whole quantity of carbonic acid formed in this experiment was 396.78 cubic inches. The quantity of azote taken into the lungs was 85.50; the quantity expired, 263.10: the increase is, therefore, 177.60. (Phil. Trans. 1808.) In another experiment of a similar nature, 2668 of gas were breathed backwards and forwards for 13 minutes: it contained 4 *per cent.* of azote. There was a deficiency of 124 cubic inches in the expired air, the largest ever observed by these gentlemen. In this experiment there was an increase of 105.08 of azote. If the azote emitted from the lungs in these experiments be supposed to have been contained in those organs before the experiments began, it will make their contents more considerable than we had before calculated. The following is a summary of four experiments on this subject:

	Barom.	Therm.	Oxygen gas, &c. inspired	Gas expired.	Deficiency.	Time.	Quantity respired in a Minute.	Azote evolved.	Inferred capacity of Lungs.
N° 1.	——	53°	3260	3193	67	9′ 20″	348	110	141
2.	30.3	70	3420	3362	58	7 25	461	177	225
3.	30.15	70	3130	3060	70	8 45	357	187	236
4.	29.4	51	2668	2544	124	13 0	205	105	133

The particulars of two analogous experiments on the guinea pig follow:

	Barom.	Therm.	Oxygen, &c. inspired.	Gas after the Exp.	Deficiency.	Carb. acid formed.	Carb. acid per Minute.	Time.	Oxygen missing.	Azote added.
N° 1.	29.05	57°	1060	1056	4	106.	1.48	$1^h\ 12^m$	54.07	50.12

Philos. Trans. 1808 and 1809.

The conclusion that the nitrogen, found in these cases, is derived from the residual air of the lungs, is so probable, that it would at once be admitted, were it not that the quantity evolved is so large, as apparently to preclude its admission. Mr. Ellis, however, in some very ingenious observations on this question, has pointed out a source of fallacy to which there is every probability that the result is to be ascribed. It is, that the air in the lungs may be in a condensed state, or occupy less volume than it would do when it is expired; and hence, in the respiration of oxygen, a larger portion of nitrogen derived from the residual air in the lungs may be given out than could be inferred from their known capacity. The structure of the lungs is cellular, and the air is diffused in cells of an immense number, and at the same time of diameters extremely small. If these cells have any degree of contractile power, this may produce

duce condenſation of the air they contain. But independent of this, it is well known, as Mr. Ellis remarks, that a ſtrong attraction or adheſion is exerted between air and the ſurfaces of all bodies; the more, therefore, the ſurface is increaſed, the greater muſt be the effect from this attractive force. Hence, under the extenſive ſurface of the cells of the lungs, it muſt operate with great effect, and reduce conſiderably the volume of the air. The abſorption of aërial fluids by charcoal, Mr. Ellis adduces as illuſtrating this operation of adheſion; and in the lungs it is ſufficiently probable, that it may be aided by the affinity exerted by the humid ſurface to the aërial matter.

All the phenomena accord much better with this view than with the concluſion that nitrogen is evolved from the blood. Thus the "production of nitrogen is always greateſt in the firſt expiration, and its quantity progreſſively diminiſhes, until towards the cloſe of the experiment, it is reduced almoſt to nothing, circumſtances which ſeem plainly to ſhew that nitrogen is no longer obtained when all the reſidual air in the lungs is removed. If this nitrogen were furniſhed by the blood independent of the reſidual air, no reaſon occurs why it ſhould thus diminiſh, and ceaſe to appear, as this air is abſtracted; for the function of reſpiration goes on, and the blood, as far as depends on itſelf, cannot be conſidered leſs fit to ſupply nitrogen. The fact, alſo, that no ſuch exceſs of nitrogen is furniſhed in natural reſpiration, militates againſt the notion of its proceeding from the blood. No exceſs of nitrogen, too, is ever afforded in other caſes, unleſs its place be ſupplied by an equal or ſuperior bulk of ſome other gas. And this affords evidence, that in this ſuppoſed evolution of nitrogen from the blood, nothing more than a mechanical ſubſtitution of one gas for another takes place." (Farther Inquiries, &c. p. 306.) Murray's Syſtem of Chemiſtry, 3d edit. v. 4. p. 498, et ſeq.

Adopting, as we do entirely, the views of Mr. Ellis on the ſubject of reſpiration (to whoſe clear, logical, and very ſatisfactory works we refer our readers for more ample information), we conclude our review of the changes, which the atmoſphere undergoes in reſpiration, in the words of his "Further Inquiry," § 621.

"From the foregoing ſeries of facts, concerning the reſpiration of the higher claſſes of animals, we feel ourſelves entitled to repeat with increaſed confidence, that 'the whole of the oxygen gas which diſappears in reſpiration is employed to form the carbonic acid produced in that proceſs.' And that 'the nitrogen gas of the air neither ſuffers any change itſelf, nor produces any direct operation on the animal ſyſtem.' Or, in the words of Meſſrs. Allen and Pepys, 'When atmoſpheric air alone is reſpired, no other change takes place in it, than the ſubſtitution of a certain portion of carbonic acid gas for an equal volume of oxygen.' (Phil. Tranſ. 1809, p. 427.) Conſequently in man, as well as in the lower animals, the converſion of oxygen gas into carbonic acid conſtitutes the only eſſential change, which the air of our atmoſphere experiences in the lungs during its reſpiration."

Aqueous Vapour contained in the expired Air.—That the air expelled from the lungs contains a certain quantity of watery vapour, is rendered very obvious by its condenſation, when we breathe cold air. It is not very eaſy to aſcertain its quantity.

Dr. Hales performed many experiments for this purpoſe: he contrived to paſs the air which he expired through a flaſk filled with woodaſhes, which, in conſequence of the potaſh contained in them, have the property of ſtrongly attracting the moiſture. By obſerving the increaſe of weight which the acid had acquired in a given time, he eſtimates that the water emitted from the lungs in 24 hours, will amount to 9792 grains, above 20 ounces. (Statical Eſſays, v. 2. p. 322—4.) The nature of his proceſs, however, did not admit of much accuracy. Dr. Menzies attempted to ſolve this problem, by actually collecting in an allantoid fitted to the mouth, the water emitted from the lungs in a given time; his eſtimate is much leſs than that of Hales; he ſuppoſed that the quantity of water exhaled in 24 hours would amount to no more than 6 ounces, or 2880 grains. (Diſſertation on Reſpiration, p. 54.) Mr. Abernethy, by breathing into a glaſs veſſel of a peculiar conſtruction, collected in an hour 180 grains of water, containing, as he ſuppoſed, a quantity of mucous matter. According to his eſtimate, the quantity emitted in 24 hours, would amount to exactly 9 ounces, or 4320 grains, but as the ſubſtance which he obtained was not pure water, there muſt be ſome deduction made from it on this account. We are not informed what proportion the water bore to the mucus diſſolved in it. Surgical Eſſays, pt. 1. 141.

The difficulty of actually collecting and weighing the pulmonary exhalation, is probably the cauſe which induced Lavoiſier in his experiments upon reſpiration, to aſcertain its quantity by a calculation, founded upon the proportion between its conſtituent parts, compared with the compoſition of the other ſubſtances which are received into and diſcharged from the lungs. He firſt determined by direct experiment the quantity of oxygen conſumed, and of carbonic acid produced; the compoſition of carbonic acid is known, and by comparing the oxygen which had diſappeared with the quantity which would have been neceſſary to form the acid, he found that the oxygen conſumed was more than ſufficient to compoſe the carbonic acid which was actually produced. He ſuppoſed that this ſuperabundant quantity of oxygen was employed in the formation of water, by uniting in the lungs with a portion of hydrogen: he eſtimates the amount of the water by knowing what quantity of it a given weight of oxygen can produce.

In the firſt memoir (1789), the quantity of water emitted from the lungs of a man in 24 hours, is ſtated to be no more than 337.18 grains. In the 2d (1790), this quantity is raiſed to 11180.57 grains, or nearly 2lbs. troy: and in the laſt experiments recorded by La Place, the quantity is ſtill more conſiderable, *viz.* 13704 grains. The proportion between the water and the carbonic acid is very various in theſe different reſearches: in the firſt they are reſpectively 337.18 grains, and 17720.89 grains, or as 19 to 1000 nearly: in the ſecond, 11188.57 and 8450.24, or as 1323 to 1000; and in the third, 13704 and 7550.40, or as 1815 to 1000. Such diſcordant reſults can have no other effect than that of diminiſhing our confidence in the whole of them.

Mr. Murray breathed into a bladder containing acetate of potaſh, a very deliqueſcent ſalt, and calculated the quantity of vapour expired by the increaſe of weight in the bladder and its contents, after the expired air had cooled. In this way he inferred that three grains of watery vapour are expelled from the lungs in a minute. Syſt. of Chemiſtry, v. 4. p. 497.

There are two ways of explaining the production of the watery vapour expelled from the lungs: by evaporation of the mucous fluid covering the inner ſurface of the air-tubes and veſicles by the conſtant paſſage of the air to and from theſe parts, which are kept at a temperature of about 98°; or by exhalation from the pulmonary or bronchial blood-veſſels. The ſecretion of the mucous membrane of the lungs muſt undergo evaporation, under the circumſtances of its

its expofure to the atmofpheric current in refpiration, according to the ordinary operation of phyfical laws: this, therefore, feems the moft probable fource of the expired water.

Lavoifier conceived that the water is generated in the lungs; hydrogen being evolved from the venous blood, and uniting with a part of the oxygen of the infpired air. But this liberation of hydrogen is not fupported by a fingle proof, or fhadow of proof; and we have every reafon to believe that all the oxygen confumed in breathing is employed to form carbonic acid.

III. *Changes produced in the Blood by Refpiration.*—Soon after the doctrine of the circulation had been generally received, the diftinction between arterial and venous blood was pointed out, and it was underftood that this fluid is changed from the latter into the former ftate in the lungs. Various conjectures were reforted to, to explain the nature and manner of this change. Some confidered the alteration to be principally mechanical; conceiving that the blood, while in the pulmonary veffels, experiences a continual and violent agitation, by means of which, its particles, before loofely mixed, and confifting of feveral heterogeneous fubftances, are communicated and perfectly united together, fo that the whole mafs acquires an uniform confiftence. Baglivi fuppofed, that the blood was rarefied, and Helvetius, that it was condenfed in the lungs; Boerhaave thought that its particles acquired that peculiar organization, which he deemed effential to the exiftence of perfect blood. Other philofophers, as Harvey, Boyle, Hales, and Haller, were of opinion, that the blood emitted fome noxious or fuperfluous matter in its paffage through the lungs. Some again fuppofed, that the change from venous to arterial was caufed by fomething imparted from the air to the blood.

Thefe vague fpeculations were foon fuperfeded by the more certain information deduced from experiment and obfervation. We have already enumerated the proofs afforded by the refearches of Lower, Cigna, Prieftley, Lavoifier, Davy, and others, that the change of the blood from venous to arterial is effected by expofure to the oxygenous gas of the atmofphere in refpiration; and that a fimilar change, in colour at leaft, is effected by fuch expofure out of the body: the alteration being accompanied, in both inftances, with a change in the compofition of the air.

The proofs, that refpiration is the fource of the change in colour juft alluded to, that it is ftopped in living animals when breathing is interrupted, and goes on again when the refpiratory procefs is refumed, will be found in the article LUNGS.

But is there no other alteration in the properties of the blood confequent on refpiration, befides its change of colour? Undoubtedly there muft be fuch further alteration, for life is quickly ended, if this converfion of venous into arterial blood be ftopped; and we fhall prefently ftate our opinion, that carbon is exhaled from the pulmonary veffels; but chemiftry has not yet fhewn us any difference of compofition beween the two kinds of blood.

"When (fays Mr. Murray) we examine chemically the properties of arterial and venous blood, we find no other difference between them than that of colour. They contain the fame principles, and are fubject to the fame changes from chemical agents. The difference of colour, however, points out fome difference in compofition, though it may be too flight to be difcovered by analyfis; and when we examine the phenomena of refpiration, which are intimately connected with the change of venous to arterial blood, we find, that fuch a difference muft exift." Syftem of Chemiftry, vol. iv. p. 489.

Even the changes of colour of the blood are not well underftood. We know that this fluid is converted from the fcarlet to the black ftate, in the courfe of its paffage through the capillary veffels of the body. But it undergoes the fame change, when extravafated from a large artery, or when confined in an arterial tube between two ligatures. It never feems, however, to fuffer the oppofite change, except when in contact with oxygen gas, or with fome fubftance capable of furnifhing it.

That the paffage of the air through the lungs in refpiration is inftrumental in converting the chyle and lymph, poured from the thoracic duct into the venous fyftem, into blood; or, that it produces fibrine from the materials juft mentioned, has been fuppofed and afferted; but without any direct proof. We cannot, indeed, fee the chyle in the blood after it has gone through the lungs; but we know of nothing further than a mechanical admixture; and are completely ignorant of the circumftances accompanying and determining the generation of fibrine.

IV. *Theories of Refpiration.*—The principal explanations of the phenomena detailed in the preceding divifions of this article, as exhibited in the air and blood, confequently to refpiration, are detailed by Mr. Murray, in his Syftem of Chemiftry, vol. iv.; where they are followed by his own views of the fubject.

Dr. Prieftley, fays he, confidered thefe phenomena as owing to the difengagement of phlogifton from the blood in the lungs, and its combination with the air (Philof. Tranfact. 1776); a theory modified and rendered more comprehenfive by Crawford (Experiments and Obfervations on Animal Heat). Regarding hydrogen as the phlogiftic principle, and fuppofing it to exift in the blood in that ftate in which it is difengaged from vegetable fubftances by heat, the heavy inflammable air of the older chemifts, the carburetted hydrogen of the modern nomenclature, he fuppofed that this hydro-carbon, as it was named, is communicated to the blood in the extreme veffels, by which the converfion from the arterial to the venous ftate is occafioned; in the lungs, he concluded, it is given out, and in its nafcent ftate, or its tranfition to the elaftic form, it combines, he fuppofed, with the oxygen of the air, and forms the carbonic acid gas and watery vapour expired, while the blood, deprived of its hydro-carbon, returns to the arterial ftate. The fame explanation nearly was given by Lavoifier; at leaft he advanced the opinion, that the carbonic acid gas and watery vapour of the expired air are formed by the combination of carbon and hydrogen from the blood with oxygen in the lungs.

Lavoifier had alfo fuggefted, that the combination of oxygen with carbon might take place in the courfe of the circulation (Mem. de l'Acad. des Sciences, 1777, p. 191.), that the oxygen which difappears in refpiration may be abforbed by the blood, while carbonic acid may be given out fully formed. This hypothefis was afterwards endeavoured to be eftablifhed by Haffenfratz and Lagrange (Annales de Chimie, tom. ix. p. 261.) They obferve, that venous blood expofed to oxygen acquires a vivid red colour, which foon changes to a purple hue; and that arterial blood placed in vacuo, or in contact with any gas which does not contain oxygen, quickly affumes the dark purple colour. They conclude, therefore, that the florid red colour of the blood is the refult of the abforption of oxygen, while the dark venous colour arifes from the intimate combination of that oxygen with a portion of the carbon and hydrogen which the blood contains. According to this theory, oxygen is abforbed by the blood in the lungs, remains in the arterial blood for a time in a ftate of folution, or loofe combination,

bination, but it gradually paffes, in the extreme veffels, into more intimate combination with carbon, forming carbonic acid, in confequence of which the blood paffes to the venous ftate; and from this venous blood the carbonic acid is difengaged in the lungs, and a new portion of oxygen abforbed.

Thefe two hypothefes have divided the opinions of phyfiologifts. They are both, however, defective: their principles are not proved, and they involve fuppofitions incompatible with the laws which appear to regulate the chemical actions that proceed in the animal fyftem. No proof is given, in the fyftem of Crawford, of hydro-carbon being communicated to the blood in the extreme veffels; nor is it eafy to imagine any fource whence this principle in an infulated ftate can be derived; for, although it has been imagined by Crawford, that it may have its origin in the folid parts of the fyftem being abforbed, this is refuted by the confiderations, that this abforption is performed not by the veins, but by the lymphatics; that it is not fufficiently uniform, nor limited to carbon and hydrogen; that to whatever extent it may be carried, the blood muft, in a ftate of health, depofit as much as is removed; and that there is no evident caufe by which the carbon and hydrogen can be feparated from the other elements, and be brought into binary combination. And, in the theory of Haffenfratz, though it were granted, that a portion of oxygen is abforbed by arterial blood, there is no proof that this is combined merely with carbon, and that carbonic acid, the refult of this combination, is contained in venous blood. We have even proof that the latter fuppofition cannot be juft; for, when arterial blood is expofed to carbonic acid gas until its colour is darkened, it does not recover its florid hue from fubfequent expofure to oxygen (Prieftley, Experiments on Air, vol. iii. p. 363. 365.), and is therefore not venous blood.

Neither are the changes which thefe hypothefes fuppofe, analogous to the ufual chemical operations of the animal fyftem, or fufficiently connected with the purpofes which the blood ferves in its circulation. They both fuppofe, that the changes which the blood undergoes, depend not on alterations in its compofition, ftrictly fpeaking, but on the alternate communication and abftraction of a principle held by it in a ftate of folution, and which appears to ferve no purpofe in the animal economy, but is affumed merely to account for the phenomena of refpiration. But when the general facility of combination in the principles of animal matter, and the tendency which the actions of the veffels have to form them into ternary or quaternary compounds, are confidered, there is little probability in the fuppofition of the one hypothefis,—that oxygen fhould be abforbed by the blood in the lungs, without immediately altering its compofition; that, without being attracted by any of the other principles of the blood, or influenced by the other chemical changes going on in the fyftem, it fhould be merely combined with carbon, in the proportion neceffary to form carbonic acid; and that this carbonic acid, without affecting the ultimate compofition of the blood, fhould be carried the whole length of the venous circulation, and thrown out at the lungs; or in thofe of the other, that carbon and hydrogen fhould be brought into a ftate of binary combination in the extreme veffels, and fhould be held merely diffolved by the venous blood, until acted on by the oxygen of the air in refpiration.

Still lefs are thefe changes connected with the known changes which the blood fuffers; for no relation is traced between the proceffes of affimilation or of fecretion, and the fuppofed communication of hydro-carbon, or the combination of carbon and oxygen, in the extreme veffels. In the theory of refpiration, the converfion of arterial into venous blood ought to be confidered as connected with thefe proceffes; and this converfion, as well as that of venous into arterial blood, muft be regarded as arifing from changes in the ultimate compofition of the known proximate principles of the blood, and not from the alternate communication and abftraction of a principle which it holds diffolved in it, or in what is termed a ftate of loofe combination. According to this view of the fubject, Mr. Murray gives the following explanation of thefe phenomena.

The blood is the fource whence the animal products are formed. Its expenditure is fupplied by the chyle, a fluid lefs completely animalized than the blood itfelf. The peculiar character of animal matter, with regard to compofition, is a large proportion of nitrogen, and a diminifhed proportion of carbon. It may therefore be inferred, that in the extreme veffels, where the animal folids and fluids are formed, the general procefs will be the feparation from the blood of thofe elements of which animal matter is compofed; and that, of courfe, carbon, which enters more fparingly into its compofition, will exift in the remaining blood in an increafed proportion. This is accordingly the general nature of the converfion of arterial into venous blood. Nitrogen, hydrogen, and other elements, are fpent in the formation of new products, and the proximate principles of the blood, probably the craffamentum chiefly, remain with an increafed proportion of carbon. In this ftate it is expofed to the atmofpheric air in the lungs, the oxygen of which abftracts its excefs of carbon, and forms the carbonic acid expired, and this conftitutes the converfion of venous into arterial blood.

There is little reafon to fuppofe, that any combination of the oxygen of the air with the hydrogen of the blood takes place. The fuppofition that it does, and that this is the fource of the watery vapours expired, originated in the hypothefis of Crawford, which fuppofed hydro-carbon to be difengaged from venous blood. No fact has been ftated in its fupport; it is a combination which can apparently ferve no purpofe in the animal economy; for hydrogen exifts in as large a proportion, (and even in a larger,) in animal as in vegetable matter. And the degree of evaporation from a moift furface, fo extenfive as that of the internal furface of the lungs, at the temperature of 96°, is adequate to account for the whole of the watery vapour expired.

The converfion of arterial into venous blood, is thus confidered in connection with the other chemical changes going on in the fyftem, and is fubfervient to them. In the extreme veffels, the conftituent principles of the blood are expended in the nourifhment of the folid fibre; in the formation of the fecreted fluids; and in the fupport perhaps of the living powers. Of thefe principles, carbon is that contained in the fmalleft proportion in the folids and fluids; it is, therefore, that of which there is the leaft expenditure, and confequently it muft be prefent in a larger proportion in the blood, after it has undergone thefe changes. To preferve the due proportion, and prevent it from accumulating, it muft be difcharged by fome other procefs. Hence the neceffity of the application of oxygen to the blood in the lungs, and the origin of the carbonic acid which is uniformily difcharged. We thus, too, trace the procefs of animalization from the reception of the aliment to its completion. All animals live directly or indirectly on vegetable matter. The principal difference in the compofition of vegetable from that of animal fubftances, is in the former containing a larger proportion of carbon. Refpiration is the function by which this difference is eftablifhed. The aliment received into the ftomach, is foon formed into a fluid capable of affimilating with the blood. It is conveyed to the lungs, and loses part of its carbon, or is partially animalized. It is then distributed through the system, and, in the extreme vessels, along with carbon, parts with so much hydrogen, oxygen, nitrogen, and other elements, as to leave carbon predominant.

It might be supposed, that in any view, such as that which has been now given, there must be some difficulty in conceiving that oxygen gas should combine with carbon with so much facility, at a temperature much lower than that which is in general necessary for their union, and this, too, with the intervention of the coats of the vessels through which the blood circulates. On attending, however, to the objection, it will be found to have no real force. Although carbon, in its solid and insulated form, requires to be raised to a high temperature to cause it to combine with oxygen, yet when it makes part of a ternary or quaternary combination, in which state its cohesion no longer opposes the combination, it is abstracted, and combined with oxygen at any natural temperature. It is thus that many vegetable and animal substances, when humid, are altered by exposure to the air, and carbonic acid formed. Blood itself is acted upon in this manner. It suffers a change precisely similar to that which it undergoes in the lungs, and this more or less rapidly, and to a greater or less extent, according to the quantity of oxygen present, and the degree of agitation used. Arterial blood was exposed by Fontana to atmospheric air for three minutes, when no perceptible alteration was occasioned in the purity of the air: they were then agitated together for three minutes: the volume of air was diminished and its purity impaired. When oxygen gas was substituted for atmospheric air, the alteration was still more considerable, its purity being diminished when agitation was avoided; and when it was agitated, the diminution in purity and volume was still greater. In all these experiments, carbonic acid was also produced. (Opuscules Physiques, pp. 334, 335.) They therefore prove, that oxygen can attract carbon from arterial blood. With venous blood, the formation of carbonic acid is, according to Luzariaga, still greater. (Dissertatio Inauguralis, p. 53, 54.) If, therefore, oxygen can abstract carbon from the principles of the blood, under such circumstances, it is evident it must do so still more rapidly during respiration, where the circumstances are so much more favourable, where there is comparatively a high and uniform temperature kept up, where the blood is exposed on an extensive surface, and in a state of extreme division, and where that surface, as well as the air itself, are rapidly renewed.

Nor can it be supposed, that the thin membrane which forms the coats of the vessels through which the blood circulates can oppose an obstacle to this reciprocal action. Every humid substance is permeable through its whole substance to elastic fluids, and is penetrated by them. Animal membrane, in a much denser state than that which forms the coats of the extreme blood-vessels, is, when humid, pervious to gaseous fluids; and what is in point in the present case, through such membranes, when humid, oxygen can act on blood, and communicate to it the florid colour, the same as when blood is freely exposed to it. Thus, Priestley found by experiment, that if a quantity of black blood were inclosed in a moistened bladder, which was tied very close, on hanging it in a free exposure to the air, it acquired "a coating of a florid colour, as thick as it would have acquired if it had been exposed to the open air; so that this membrane had been no impediment to the action of the air on the blood." Mr. Hunter mentions a similar experiment: "I covered," says he, "the mouths of vessels filled with venous blood with gold-beaters' skin, touching the surface of the blood, and the blood constantly became of a florid red on the surface, and even for some depth." (Treatise on the Blood, p. 62.) Nor is there any reason to believe, as has been contended, that in the living solids this property is suspended, for it is one connected merely with mechanical structure, and the influence of humidity. The blood, therefore, may be considered, when circulating in vessels so fine, as exposed to the action of oxygen nearly as if no membrane were interposed: a part of that oxygen approximated to it will combine with a portion of its carbon, and the carbonic acid, when formed, will, from its elasticity, recede and be discharged. The whole action is purely chemical, and precisely the same as that which is exerted between air and blood out of the body, favoured only by the circumstances of exposure, temperature, and agitation, under which it takes place." P. 502.—510.

After adverting to the arguments, by which it is shewn that no gas can pass through the membranes of the bronchial cells and pulmonary vessels from without, nor any substance pass from within through these parts, to unite in the lungs by ordinary chemical affinity, consequently that the carbonic acid is not formed by the union of carbon and oxygen in the blood; and to the facts, in which carbonic acid is formed in the lower animals and even in man, by the skin, where we have no proof of any absorption of oxygen, or passage of it through the animal textures, Mr. Ellis declares his opinion, in which we entirely coincide, that the carbon supplied in human respiration is truly an animal excretion, performed by the exhalent vessels, which exist in such wonderful numbers in the lungs; consequently, that it depends primarily, like other excretions, on the due circulation and distribution of the blood, and is more or less affected by all its variations. The changes in its quantity have been found very considerable, according as the individual was at rest or in motion, fasting or with a full stomach, &c. in the experiments already noticed of Lavoisier and Seguin. We conceive, then, that the carbon, thus exhaled or excreted in the lungs, combines in the air-cells with the oxygen of the atmosphere to form the carbonic acid expired.

As the emission of carbonic acid in respiration is carried on through the whole period of living action, and is essential to the continuance of it, some ulterior source must be provided, from whence its supply may be duly maintained.

"To the organs of digestion, assimilation, and secretion alone, we are enabled to trace it; but the mode in which it is reduced to that state in which it is afterwards expelled by the surfaces of the lungs and skin, involves a knowledge of the nature and qualities of our food, of the various and successive changes which it is made to undergo in the system, and of its distribution by the blood to the different organs of secretion, according to the several uses which it is afterwards destined to answer: concerning all of which subjects, we have of late succeeded in getting rid of much error and absurdity, but have not in any instance attained to complete knowledge." Ellis's Inquiry, ch. 5.

V. *On the Respiration of the different Gases.*—No aëriform fluid, says Dr. Bostock, except the compound of oxygen and azote which exists in the atmosphere, is adapted to the permanent support of life. Of the other gases, there are some which, on account of their irritating nature, it is absolutely impossible to receive into the trachea; these properly constitute the nonrespirable gases. There are, however, others which it is possible to inspire, though their employment is followed sooner or later by the extinction of life. We shall detail some of the principal experiments that have been performed on this subject, as the nature of the change produced

duced upon the blood by common refpiration may be in fome meafure illuftrated, by obferving the effects which follow the ufe of the other gafeous bodies.

Soon after the difcovery of the power which the oxygenous part of the atmofphere poffeffes, of fupporting animal life, feveral trials were made of the effects which would refult from breathing it in an unmixed ftate. The accounts given by thofe who were the fubjects of thefe trials were various; Dr. Prieftley, who firft made the experiment, conceived that he felt an agreeable lightnefs in the cheft (Obf. on Air, v. ii. p. 162.); fome perfons fuppofed that it produced exhilarating effects upon the fyftem, while others imagined that the employment of this gas was followed by uneafinefs and pain about the region of the thorax. Thefe different fenfations muft be attributed, in a great degree, to the effects of imagination; in part, however, they may be afcribed to the gas which was employed in the earlier period of the pneumatic experiments having been often in an impure ftate, mixed with acid, acrid, or metallic particles. A difference in the effects produced by the refpiration of the gas, ought perhaps, in fome degree alfo, to be imputed to the manner in which it was received into the lungs, whether only in fmall quantities, or by deep and laborious infpirations, and whether it was employed in a condenfed or a rarefied ftate.

As Dr. Prieftley was the firft perfon who, himfelf, refpired oxygenous gas, fo he was likewife the firft who obferved the effects which it produced upon animals altogether immerfed in it. His experiments were performed upon mice; they decidedly proved the power which this gas poffeffes of fupporting animal life, but no other certain conclufions can be deduced from them. M. Lavoifier afterwards turned his attention to this fubject, and in the experiments upon guinea pigs, to which we have already referred, he noticed with more accuracy the effects refulting from the refpiration of oxygen. He examined the ftate of the internal organs of animals which had been for fome time confined in this gas, and he conceived that a degree of rednefs and turgefcence of the veffels was produced, and other effects which indicated that the fanguiferous fyftem had been in a ftate of increafed action. (Soc. Roy. de Médécine, 1782, 1783, p. 576.) There is, however, reafon to infer, that in this cafe, either the gas employed was in an impure ftate, or that there were fome circumftances attending the fituation of the animals, or the manner in which the experiment was conducted, which affected the refults, for the fame philofopher, in the fubfequent memoir of 1789, where there appears to have been the greateft attention to accuracy, and where the moft perfect apparatus was employed, forms entirely oppofite conclufions. In this paper, we are informed, that he confined guinea pigs in pure oxygen, and in mixtures of oxygen and azote, in different proportions, until the former conftituted only one-fifteenth part of the compound. In all thefe cafes, he found that the fame quantity of oxygen was confumed, a circumftance, he obferves, in which refpiration differs remarkably from combuftion, though, in many refpects, thefe operations are fimilar to each other. The effects produced upon the animals were precifely the fame, whether they were confined in pure oxygen, or in any of the mixtures of it, except that when the proportion of azote was very large, they exhibited marks of drowfinefs. The author exprefsly informs us, that neither the temperature nor the circulation were in any refpects affected by the infpiration of pure oxygen for the fpace of feveral days. (Acad. des Sciences, 1789, p. 573.) Thefe experiments muft be confidered as very valuable; there is no reafon to doubt their accuracy, and they may be relied on with more confidence, as the author feems to have had no peculiar theory in view when he performed them; indeed the refults are different from what we might previoufly have expected, and are unfavourable to the analogy which Lavoifier had always endeavoured to eftablifh between refpiration and combuftion.

We have an account by Dr. Higgins of the refpiration of pure oxygen by the human fubject; in one experiment, thirty-eight pints of this gas were refpired without interruption. No inconvenience was experienced, a fenfe of warmth was, however, produced in the cheft, and the pulfe was confiderably quickened, (Minutes of a Society, &c. p. 144—6.) Dr. Higgins, in a fecond experiment, breathed a quantity of oxygen under an additional preffure, and by very full infpirations. He conceived that by thefe means its confumption was much promoted (ibid. 152.); but more numerous and accurate experiments will be required before this inference can be fairly eftablifhed. Effay on Refpiration, p. 139—144.

In the year 1794, Dr. Beddoes publifhed his experiments upon this fubject. (On Factitious Air, pt. i. p. 13.) They were performed upon rabbits, and the attention was principally directed to an examination of the ftate of the internal organs of the animal, after it had been fubjected for fome time to the influence of pure oxygen. In detailing the refults, we fee fuch obvious marks of the influence of the author's pre-conceived notions, that our confidence in them is much diminifhed; and this unfavourable impreffion is ftrengthened by finding that they do not coincide with the reports of other very accurate obfervers. See Boftock on Refpiration, p. 144, et feq.

Mr. Davy has alfo recorded fome trials, which he made with oxygen gas; the refults of which, fo far as they regard the chemical changes of the air itfelf, we have noticed in a previous part of this article. Refearches, p. 444.

Meffrs. Allen and Pepys made fome experiments on the refpiration of oxygen. The pulfe was raifed about 15 beats in a minute, a gentle glow and perfpiration were produced over the whole body, and nothing elfe remarkable occurred. The refpiration of the gas was continued about ten minutes in thefe trials; and the effects foon fubfided. We have detailed the refults of their obfervations concerning the changes of the air, in that divifion of this article in which the quantity of carbonic acid, produced by breathing, is mentioned.

It thus appears that we have no direct proof that the refpiration of oxygen, for a fhort period, is injurious to the animal economy. Whether a much longer ufe of the gas would be hurtful, and what peculiar morbid action or condition of parts would be induced, we have no means of determining.

Among the remaining refpirable gafes, that which appears to be the leaft injurious to the living body is the oxyd of azote. This aëriform fluid was firft difcovered by Dr. Prieftley, and was by him fuppofed to be "in the higheft degree noxious to animals." (Obf. on Air, v. ii. p. 55.) The fociety of Dutch chemifts, who afterwards examined its properties with more accuracy, coincided with Dr. Prieftley, as to its effects upon animal life. (Journal de Phyfique, t. xliii. p. 329.) The experiment was, however, repeated by Mr. Davy, and he difcovered not only that this gas may be refpired for a fhort time without inconvenience, (four or five minutes,) but that the employment of it is fucceeded by a fingular excitement of the nervous fyftem, which differs from that produced by alcohol and

opium,

opium, in not producing a subsequent state of exhaustion. The description of its effects in the "Researches" is very interesting. Mr. Davy infers from his experiments, that this gas is absorbed in large quantities by the venous blood. This blood, when exposed to the gas out of the body, becomes of a brighter purple, and carbonic acid is formed. We have no doubt, therefore, that carbonic acid is formed when this gas is respired; the gas being decomposed, so that the carbon of the venous blood can unite with its oxygen. We have already spoken at length against the notion of any air being absorbed by the blood in breathing; and we may refer to Mr. Ellis's Inquiry, chap. iv., for satisfactory arguments against the supposed absorption of this gas in particular.

Hydrogenous gas has been frequently respired, and it is now pretty generally agreed, that it is altogether passive when received into the lungs, and that death succeeds the employment of it in consequence of the exclusion of oxygen, in the same manner as by suffocation, or drowning. M. Lavoisier distinctly ascertained this fact, in his experiments related in the memoir of 1789, and it has been since confirmed by Mr. Davy. (Researches, p. 466.) It must be remarked, however, that a contrary opinion respecting the effects produced by the respiration of hydrogen has been maintained by some eminent chemists, even by Dr. Priestley himself (Obs. on Air, v. i. p. 229.); but his experiments were made in the earlier period of the pneumatic chemistry, when the gases were frequently employed in an impure state, and the experiments of Mr. Davy clearly demonstrate that hydrogenous gas produces different effects upon the system, according to the substances from which it is procured.

The experiments that have been made upon the subject of azotic gas are few and imperfect; it has been generally supposed, that it exercises no noxious effects upon the blood, but, like hydrogen, destroys life simply by preventing the access of oxygen. Dr. Higgins indeed remarks, that an animal dies sooner when immersed in this gas, than from the simple interruption to respiration (Minutes of a Society, p. 133.); but we are not informed upon what data this opinion is founded. Mr. Davy likewise experienced the sense of suffocation more speedily from the use of azote, than from that of hydrogen, but it appears that the gas employed in the experiment contained a quantity of carbonic acid, to which we may, with great probability, ascribe its noxious effects; and the same philosopher, when speaking in general terms of the action of azote in respiration, seems to consider it as merely excluding oxygen. This opinion is adopted by Dr. Thomson, and was uniformly maintained by M. Lavoisier. It would certainly appear reasonable to conclude à priori, that a substance which enters so largely into the composition of the atmosphere, and which consequently composes so great a proportion of the contents of the lungs, could not exercise any noxious effects upon the animal system.

The only remaining gases which can be received into the lungs are the carbonated hydrogen or hydro-carbon, sulphurated hydrogen, and carbonic oxyd. They occasion death immediately, but produce some change in the blood. If hydro-carbon be inspired in an undiluted state, it is followed by instant death; and when employed in small quantity only, mixed with atmospheric air or with oxygen, if it be used for any length of time, it induces vertigo, dimness of sight, convulsions, loss of sensation, and, in short, every symptom of approaching dissolution. It evidently acts more rapidly and powerfully than those gases which merely exclude oxygen from the blood, and must consequently be considered as exercising a positively noxious influence upon the animal economy. For an account of the respiration of sulphuretted hydrogen, see the Journal de Physique, vol. lvi. p. 35.

All the remaining gases are found to be strictly non-respirable, *i. e.* incapable of being admitted into the trachea. It is obvious that this must be the case with the irritating acid or alkaline gases, and with the nitrous gas, which, during its passage into the lungs, must unavoidably be brought into contact with oxygen, and thus produce nitrous acid vapour. The only substance, respecting the respirability of which there could be any doubt, is the carbonic acid gas, which, though possessed of the decided characteristics of an acid, exhibits them in a much slighter degree than that in which they generally exist. The impossibility of taking it into the lungs, even by the most powerful voluntary efforts, when it composes a large proportion of the air, was, however, proved by the experiments of M. Pilatre de Rozier, executed with that intrepidity which formed so remarkable a trait in the character of this philosopher. Bostock's Essay, p. 149—153.

He went into a brewer's tub, while full of carbonic acid gas, evolved by fermentation. A gentle heat manifested itself in all parts of his body, and occasioned a sensible perspiration. A slight itching sensation constrained him frequently to shut his eyes. When he attempted to breathe, a violent feeling of suffocation prevented him. He sought for the steps to get out; but not finding them readily, the necessity of breathing increased, he became giddy, and felt a tingling sensation in his ears. As soon as his mouth reached the air, he breathed freely, but for some time he could not distinguish objects: his face was purple, his limbs weak, and he understood with difficulty what was said to him. But these symptoms soon left him. He repeated the experiment often, and always found, that as long as he continued without breathing, he could speak and move about without inconvenience; but whenever he attempted to breathe, the feeling of suffocation came on. Journal de Physique, vol. xxviii.

Blumenbach made an experiment on three dogs of nearly the same size, to shew in a comparative view how long three different aërial fluids could support life. He prepared a bladder with a pipe attached to it, and holding about 20 cubic inches. This, filled with oxygen, was tied in the trachea, and the animal died in 14 minutes. The second animal perished in six minutes, when the same bladder, filled with atmospheric air, was placed in the same way in the trachea. The bladder containing the air, at the end of the last experiment, was put into the trachea of the third animal, which died in four minutes. Instit. Physiolog. 1798, p. 114, note *q*; or more at length in his Medicinische Bibliothek, vol. i. p. 174, et seq.

VI. *Effects produced on the Air by the Respiration of Animals.*—The results of observation warrant us in asserting that no living being can subsist long without a supply of fresh air. That insects die, when their stigmata are covered with oil or honey, has been long known. "Oleo illito insecta omnia exanimantur," says Pliny. Mr. Derham found that wasps, bees, hornets, and grasshoppers, seemed dead in two minutes, when placed under the exhausted receiver; but revived in two or three hours, on being restored to the air, even although they had remained in vacuo 24 hours. (Physico-Theology, p. 8, 7th edit.) Snails survived several hours in the exhausted receiver, newts two or three days, and leeches five or six. (Hutton's Math. Dict. art. *Air-pump.*) Zoophytes, according to Davy, require air in the water which they inhabit, and act on it like fishes. (Beddoes's Contributions, p. 138.) When some pepper-water had remained in vacuo 24 hours, some of its animalcules were

were dead, and some alive. (Physico-Theol. p. 8.) Spallanzani never found any animalcules produced in vegetable infusions in vacuo. When infusions, containing animalcules, were placed under the exhausted receiver, they lived many days, but perished sooner than others of the same kind in the open air. (Tracts, p. 1, 2.) Hooke found that the eels of vinegar died in a very short time, when the fluid was put into a phial, and stopped close. (Microgr. p. 217.) Scheele inclosed leeches in a phial, with a little air: they lived only two days, although they would have lived as many years, if the water had communicated with the air. Mr. Ray remarked, that fishes cannot live in water without air: they will live in a vessel of water with a narrow mouth for months or years; but if the vessel be stopped, so as wholly to exclude the air, or interrupt its communication with the water, they will be suddenly suffocated. (Wisdom of God in the Creation, p. 81.) Dr. Priestley confined several small fishes in a vessel, containing three pints of rain water, that had been previously well boiled to deprive it of its air, and they lived only between three and four hours. (Obs. on Air, vol. v. p. 139.) Mr. Davy introduced a large thornback into a jar, containing three cubic inches of water, which had been deprived of its air by distillation through mercury: he was very quiet for four minutes and a half, but then began to move about, and, in seven minutes, had fallen on his back, but still continued to move his gills. In eleven minutes, he was motionless, and when taken out, after thirteen minutes, he did not recover. (Researches, p. 367.) Amphibious animals, likewise, cannot live without air, but its deprivation is not immediately fatal to them. Frogs and toads bear the pump for two or three hours, and a frog recovered on exposure to the air, after remaining in vacuo seemingly dead for eleven hours. Hence we see, that to all these animals, whether inhabiting the air or the water, a constant renewal of fresh air is required, while the actions of life continue. What then are the changes produced on atmospheric air, by these several classes of animal beings, whereby it is rendered so essential to the maintenance of vital action?

For the first and most accurate knowledge we possess concerning the changes which the air suffers by the respiration of insects, we are indebted to the labours of Scheele, who placed bees and flies in phials with air, and found the oxygen removed, and carbonic acid gas substituted in its place. (On Air and Fire, p. 148—155.) M. Vauquelin examined the subject more accurately. The experiments of this excellent chemist were made on the grasshopper (gryllus viridissimus), which is described as having 24 stigmata, or breathing pores, ranged parallel with, but exterior to, two white lines, extending longitudinally on the middle of the belly. In this insect they are of an oval form, but they vary in shape in different insects; and it is chiefly by their mediation, that the changes on the air are effected. A female grasshopper was placed in eight cubic inches of atmospheric air: it breathed from 50 to 55 times in a minute, and lived 36 hours. The air had not sensibly diminished in volume, but, when examined by the test of lime-water, carbonic acid was detected; and after this was removed, the remaining air still extinguished a taper. When many grasshoppers were put at the same time into a given bulk of air, and left till they died, the oxygen gas was nearly, but not entirely, consumed; and phosphorus melted in the residual air, when heat was applied, but burned very little. A male grasshopper lived 18 hours in six cubic inches of oxygen gas: its respiration was oppressive, and it breathed from 60 to 65 times in a minute. The volume of air was not sensibly diminished, but it lost $\frac{5}{100}$ths of its bulk by being washed in an alkaline solution. (Ann. de Chimie, tom. xii.) From these facts we learn, that insects, by their respiration, consume the oxygenous portion of the air; that carbonic acid is, at the same time, produced; and that, when all the oxygen gas has disappeared, the animal no longer survives.

M. Huber found, that bees very speedily die, when put into nitrogen gas; but that they survive in a close vessel of atmospheric air, until almost the last atom of its oxygen gas is consumed. (Mem. sur la Germination, &c.) We likewise confined, says Mr. Ellis, a number of flies in a flask, containing nine cubic inches of air, and then inverted it into a tall glass of mercury. By the third day, the flies were all dead, and the mercury had risen considerably into the neck of the flask. The residual air lost about $\frac{18}{100}$ths by agitation with lime-water, and the remainder did not suffer the smallest diminution by being placed in contact for two days with phosphorus. These results, therefore, agree with those obtained by Vauquelin, and prove farther, that, by the respiration of flies, the whole of the oxygen gas of the air disappears, and that a bulk of carbonic acid nearly equal thereto is formed. The small diminution of bulk, also, which the air suffered, is to be regarded as a necessary consequence attending the conversion of oxygen gas into carbonic acid, and which, as it accounts for the whole loss the air experienced, seems to authorize the conclusion, that while the oxygen gas had, in this case, completely disappeared, the nitrogenous portion of the air continued undiminished, and probably unaltered.

The researches of Spallanzani and Reaumur further shewed, that the ova of insects cannot be evolved without air; that the larvæ cannot exist without it, nor undergo their change to the pupa state; and that it is equally essential to the transformation of the latter into the perfect insect. Rapports de l'Air avec les êtres Organisés, tom. i. Memoires pour servir à l'Hist. des Insectes, tom. ii.

M. Vauquelin proceeded next to investigate the changes produced on the air by the respiration of the vermes class of animals. He confined a red slug in twelve cubic inches of atmospheric air, and it lived 48 hours. The air was not sensibly diminished in volume, but it extinguished candles, and copiously precipitated lime from water. Phosphorus was melted in this air, but did not suffer any combustion or change of colour. A snail (helix pomatia) was next put into twelve cubic inches of atmospheric air, and lived four days. The oxygen gas entirely disappeared; for the residual nitrogen gas contained not an atom of vital air, and, consequently, phosphorus did not burn in it at all: it contained, however, carbonic acid. Slugs and snails, therefore, require fresh air while in an active state, the oxygen gas of which, by the function of their respiratory organs, is made completely to disappear, and a quantity of carbonic acid is produced, while the nitrogenous portion of the air remains unaltered: and when these changes are effected, living action speedily comes to an end. So exactly do these animals separate the oxygenous from the nitrogenous portion of the atmosphere, that M. Vauquelin suggests the employment of them for eudiometrical purposes. Ann. de Chimie, loc. cit.

The numerous experiments of Spallanzani on worms, snails, slugs, &c. confirm the statements of Vauquelin in all essential points. (Memoirs on Respiration. Rapports de l'Air.) He also made experiments on muscles, and several marine testacea: they consumed the air of water in which they were confined, and the water then attracted more, so as to consume all the oxygen when a small quantity of air was confined in contact with it.

We

We are indebted to Meſſrs. Humboldt and Provençal for ſome experiments on the reſpiration of fiſhes, which poſſeſs great accuracy. Their attention was firſt directed to aſcertain the quantity and compoſition of the air that exiſts naturally in river-water. For this purpoſe, they filled glaſs balloons with given quantities of water, taken from the river Seine, and expelled the air from it by ſubmitting it to ebullition. The air that came over was received in veſſels filled with mercury, or with diſtilled water recently boiled, that no foreign air might mix with that obtained from the water in the balloon. From the reſults of ten experiments, conducted in this manner, they found, that the water of the Seine contained rather leſs than $\frac{1}{30}$th of its volume of air. This air they farther found to be compoſed of about $\frac{31}{100}$ths oxygen, with from 6 to 11 *per cent.* carbonic acid, and the remainder was nitrogen gas. Mem. d'Arcueil, tom. ii.

Having thus determined the quantity and kind of air contained in a given volume of river-water, theſe chemiſts proceeded to aſcertain the changes which it experienced by the reſpiration of fiſhes. With this view, they confined young fiſhes in bell-glaſſes of river-water, inverted over mercury; and ſuffered them to remain till their reſpiration became laborious. The animals were then withdrawn, and the water, in which they had reſpired, was transferred into the balloon, and its air expelled, by ſubmitting it to ebullition, in the manner before ſtated. Seven tenches were, in this manner, confined in 4000 cubic centimeters, equal to 250.5 cubic inches of river-water, where they remained eight hours and a half. A portion of this water, equal to 2582 cubic centimeters, or 161.5 cubic inches, was then transferred from the glaſs-bell into the balloon, and its air expelled by heat. The air, thus obtained, meaſured 453 parts, at temperature 50° Fahrenheit. Theſe 453 parts were then waſhed in lime-water, by which they were reduced to 300, ſo that 153 parts of carbonic acid were thus removed. The reſidue was afterwards analyſed by combuſtion with hydrogen, and by mixture with nitrous gas; and the means of three analyſes afforded 0.035 of oxygen; wherefore it is concluded, that the 453 parts of air, obtained from water which had been in contact with the reſpiratory organs of fiſhes, conſiſted of 10.5 oxygen, 289.5 nitrogen, and 153.0 carbonic acid gas. But by former experiments, it was found, that an equal volume of pure river-water afforded 524 parts of air, conſiſting of 155.9 oxygen, 347.1 nitrogen, and 21.0 carbonic acid; conſequently, ſay theſe chemiſts, theſe ſeven tenches have *abſorbed*, in eight hours, 145.4 of oxygen, and 57.6 of nitrogen gas; and they have produced in the ſame time 132 parts of carbonic acid. (Mem. d'Arcueil, t. ii. p. 376.) Mr. Ellis has pointed out ſome ſources of fallacy, from which theſe apparent reſults may have ariſen, and it is probable from analyſis, that in fiſhes, as in other animals, the change produced by reſpiration is the converſiou of oxygen into an equivalent portion of carbonic acid.

The changes which the air undergoes from the reſpiration of Reptiles are detailed in that article. Its alterations in the breathing of mammalia and birds are the ſame as in man.

"The preceding facts," ſays Mr. Ellis, "ſufficiently ſhew, that various animals, in all the foregoing claſſes, and in every ſtage and form of their exiſtence, require the preſence of oxygen gas to maintain the functions of life; that this gas, by the exerciſe of theſe functions, is converted into carbonic acid: and that the degree in which this converſion proceeds, depends much on the healthy condition of the animal, and the vigour of its circulating ſyſtem. Since, alſo, in every inſtance where the experiments have been made with the requiſite accuracy, the bulk of carbonic acid produced, nearly or exactly equalled that of the oxygen which diſappeared, we may conclude, from analogy, that ſuch is univerſally the extent to which this change in the air takes place in animal reſpiration; and ſince, farther, the nitrogen gas of the air appears to ſuffer no neceſſary change in the exerciſe of this function, we may alſo conclude, that, as far as regards the air, the ſubſtitution of an equal bulk of carbonic acid for the oxygen gas that is loſt, compriſes the only eſſential change which the atmoſphere experiences during the performance of this animal proceſs. We have before maintained that the oxygen of the air does not enter the animal ſyſtem, either by the living function of abſorption, or by the operation of chemical affinity; and have conſequently concluded, that the union of this ſubſtance with the animal carbon takes place exterior to the veſſels of the living animal." Further Inquiry, p. 271.

Animal Heat.—Taking the ſpecific caloric of water at 1.0000, Dr. Crawford found that of arterial blood to be 1.0300, and that of venous blood 0.8928; that of oxygen gas compared to water, as 4.7490 to 1.0000; of nitrogen, 0.7936; atmoſpheric air, 1.7900; and of carbonic acid gas, 1.6454. The power of oxygen gas to ſupply heat, ſays Mr. Berthollet, is well known, and there is no ſubſtance which ſuffers ſo much of it to eſcape in the changes of its conſtitution.

In the reſpiration of animals, as well as in the germination of ſeeds, and the vegetation of plants, the oxygen gas of the atmoſphere is converted into carbonic acid. Since the ſpecific caloric of the latter is little more than one-third of that which the oxygen gas itſelf previouſly contained, it neceſſarily follows, that a large quantity of caloric is liberated, whenever this converſion of gaſes takes place. Now, in the living proceſſes juſt alluded to, the preſence of caloric is very obvious: we refer for proofs on theſe ſubjects, to the articles Heat, *Animal*, Mammalia, Birds, Fishes, Insects, Reptiles, and Vermes, in which the facts connected with their vital temperature are detailed; alſo to the two "Inquiries" of Mr. Ellis.

Since, then, all animals poſſeſs a temperature exceeding that of the medium which they inhabit, and ſince this, in man and the ſuperior animals, varies but little under every viciſſitude of heat and cold, conſiſtent with the due performance of the animal functions, there muſt exiſt in all caſes appropriate means of ſuſtaining this function. But no living powers of the animal ſyſtem are ſufficient for this purpoſe, independent of the concurring aid of external agents. No ſuppoſed attrition between the contiguous ſoft parts of the animal; no friction between the veſſels and globules of the blood; no action of the ſolid parts upon one another; no circumſtances ariſing out of digeſtion or fermentation in the living body; no imagined combuſtion of phoſphorus in the blood; no liberation of the phlogiſtic or any other principle, through the ſyſtem, can be received as ſufficient to account for the uniform height and ſteadineſs of this temperature. As, therefore, the animal ſyſtem, by virtue of its own powers, is unable, within itſelf, to produce this high degree of heat, to what external agent ſhall we have recourſe, and to what organs ſhall we refer the production of that more or leſs elevated temperature which is obſervable in all animals.

Inſects, worms, and fiſhes, which have no reſpiratory ſtructure ſimilar to that of the lungs; and reptiles, the ſurface of whoſe lungs, in proportion to that of the body, is comparatively ſmall, and whoſe blood, at each circulation, is but partially expoſed to the influence of the air, poſſeſs a

 degree

degree of heat but little above that of the medium in which they live; while the mammalia have a temperature considerably higher; and birds, whofe lungs bear the largeft proportion to their bodies, are the warmeft of all animals. The obfervation of thefe facts led naturally to the opinion, that the temperature of animals was immediately connected with the functions of the refpiratory organs; and an abundance of facts, collected and arranged by Mr. Ellis, prove that the fmall excefs of temperature, which not only the inferior animals, but which vegetables alfo poffefs, is actually derived from the decompofition of the air by thefe feveral claffes of beings, fo long as living action continues. "No explanation, however," fays Mr. Ellis, "of the mode in which the air contributes to fuftain animal heat, was attempted, till after the great difcovery of latent heat by Dr. Black. That excellent philofopher having already proved that the change effected in the air by refpiration, confifted in the formation of carbonic acid, fimilar to what happens in many examples of combuftion, afcribed the production of animal heat to the decompofition of the air in the lungs, by which its latent heat was rendered fenfible, in the fame manner as it is given out in combuftion. The blood, in its paffage through the lungs, had, he conceived, its temperature by this means raifed; and thus was rendered capable of communicating heat to all parts of the body, in the courfe of its circulation through the fyftem. To this it was objected by Dr. Cullen, that, if true, the temperature of the body ought to be greateft in the lungs, and to diminifh gradually, as the diftance from the lungs increafes, which is not according to fact. This difficulty was removed by the ingenuity of Dr. Crawford, who, by a happy extenfion of Dr. Black's doctrine, maintained, that the heat, liberated by the decompofition of the air in the lungs, paffed into the blood, and exifted in that fluid in the form of latent, or, what is now termed, fpecific heat, in confequence of which its temperature was not raifed; and that this heat, by other chemical changes, was given out by the blood in a fenfible form during its circulation.

"In what manner, then, does the air, breathed by the fuperior animals, give out its heat, to fupport that high degree of temperature above the furrounding medium, which they all poffefs? We have feen reafon to conclude, that the infpired air is decompofed in the bronchial cells of the lungs, and that all its oxygenous portion which difappears, is converted into carbonic acid, by carbon emitted from the exhalent furface of thofe organs. During this gradual converfion of the oxygen gas, a quantity of fpecific caloric, much greater than what is neceffary to maintain the elafticity of the carbonic acid that is formed, is neceffarily fet free; and to this excefs of heat, thus conftantly liberated in the lungs, by the decompofition of the air, do we look as the fource of that fuperiority of temperature, above the furrounding medium, which man and other animals, under every viciffitude of climate, are enabled to exhibit and maintain.

"But if a quantity of caloric be thus conftantly difengaged in the lungs, it may be expected that the blood, in its tranfmiffion through thofe organs, fhould acquire a certain portion of it. To afcertain this point, Dr. Crawford, purfuing the difcoveries of Drs. Black and Irvine, mixed together certain quantities of water, at the temperature of 53°, with feparate portions of arterial and venal blood; and then meafuring the heat of the mixture, at different fucceffive periods, till coagulation took place, he found that the water containing arterial blood preferved a fuperiority of temperature over that mixed with venal blood; and, from the refults of feveral trials, he concluded, that the fpecific heat of the arterial blood of a dog, was to that of the venal, as 114 to 100, and that of a fheep as 115 to 100, or as $11\frac{1}{2}$ to 10. (On Animal Heat, p. 279.) Thefe refults derive confirmation from the experiments of Mr. Coleman, who, in order to difcover the relative fpecific heat of arterial and venal blood, while yet retained in the fyftem, ftrangled a cat, and immediately opened its cheft, while the blood in the left ventricle was ftill florid. He then introduced a thermometer, through an opening in the pericardium on each fide of the heart, and it ftood at 98°: in the left ventricle the temperature was only 97°, and in the right ventricle it was nearly 99°. In fifteen minutes, however, inftead of the right ventricle poffeffing two degrees of heat more than the left, it was found to have four degrees lefs. Mr. Aftley Cooper repeated this experiment in different ways, and found invariably, that although the venal blood was fuperior in temperature at firft, yet before coagulation was complete, the arterial became from three to fix degrees warmer. (On Sufpended Refpiration, p. 42, et feq.) Thefe facts afford clear and decifive proof, that the fpecific heat of the arterial blood exceeds that of the venal, and demonftrate, likewife, that this excefs is obtained during the paffage of that fluid through the lungs.

"Admitting the lungs, then, to be the organs in which, by a decompofition of the air, the blood, as it paffes through them, obtains its heat, it is next required to fhew the fufficiency of this decompofition, to fupply heat enough for the maintenance of that fuperiority of temperature, which the warmer blooded animals poffefs." (Inquiry, p. 234—236.) For an account of the mode in which this was explained by Dr. Crawford, fee Heat, *Animal*.

Although this explanation of the production of animal heat appears fimple and fatisfactory, and has been held adequate to account for the phenomena by fuch philofophers as Black, Crawford, Lavoifier, and La Place, the evidence on which it refts is not fo clear as to have commanded univerfal affent, or entirely fet afide objections. It has, indeed, been generally allowed, that refpiration, and the changes it produces in the air and animal fluids, are effential conditions of the evolution of the caloric in animals; but it has been thought, that there are other circumftances, hitherto perhaps not well underftood, which influence the phenomena.

In external appearance the blood is the fame in all the veffels of the fœtus; is this any proof that its temperature is owing to the converfion of oxygen gas into carbonic acid?

Is the uniformity of temperature in the higher animals, under varying ftates of refpiration and circulation, and the confumption of various quantities of oxygen, whether in the fame or different individuals, confiftent with the theory? and can local variations of temperature be explained from it?

Some recent inveftigations of Mr. Brodie are particularly calculated to increafe our doubts on the fubject. Having pithed or decapitated animals, he kept up artificial refpiration, and thus maintained their circulation. The blood continued to be changed in the lungs from venous to arterial, and from arterial to venous, in the general circulation.

The refpective colours of the two kinds of blood could not be diftinguifhed from thofe which they exhibit in living and healthy animals. Yet the temperature of an animal thus heated, funk fafter than that of another fimply killed and left to itfelf. The following table exhibits the refults of fuch a comparative experiment.

Time.	Rabbit with artificial Reſpiration.		Dead Rabbit.	
	Thermometer in the Rectum.	Thermometer in the Pericardium.	Thermometer in the Rectum.	Thermometer in the Pericardium.
Before the experiment	$100\frac{1}{2}$		$100\frac{1}{2}$	
30 minutes -	97		99	
45 - -	$95\frac{1}{2}$		98	
60 - -	94		$96\frac{1}{2}$	
75 - -	92		95	
90 - -	91		94	
100 - -	$90\frac{1}{2}$	$87\frac{1}{2}$	93	$90\frac{1}{2}$

The animal, in whom artificial breathing was kept up, inſtead of having its heat maintained by the converſion of arterial into venous blood, and *vice verſâ*, was thus actually cooled by the air conveyed into its cheſt.

Having thus aſcertained, that the ordinary changes are effected in the blood by its circulation and artificial reſpiration in a decapitated animal, Mr. Brodie proceeded to ſhew, that the oxygen of the air undergoes its uſual converſion into carbonic acid. He found, that a living rabbit formed 50—56 cubic inches of carbonic acid in an hour; a decapitated animal, in whom artificial reſpiration was kept up, emitted 40—48 cubic inches in the ſame time. The thermometer in the rectum of the latter had fallen from 97 to 90, while in another rabbit left to itſelf, but ſimilarly treated in all other reſpects, it had fallen only to 91. In a rabbit poiſoned with woorara, or the eſſential oil of bitter almonds, not decapitated, and in which artificial breathing was kept up, 51 cubic inches of carbonic acid were emitted in an hour. The thermometer in the rectum had ſunk to 91 in 30 minutes; while it ſtood in another animal treated exactly the ſame, excepting the artificial breathing, at 92.

Theſe experiments ſeem fully to warrant Mr. Brodie's concluſion, "that in an animal in which the brain has ceaſed to exerciſe its functions, although reſpiration continues to be performed, and the circulation of the blood is kept up to the natural ſtandard, although the uſual changes in the ſenſible qualities of the blood take place in the two capillary ſyſtems, and the ſame quantity of carbonic acid is formed as under ordinary circumſtances; no heat is generated, and (in conſequence of the cold air thrown into the lungs) the animal cools more rapidly, than one which is actually dead."

See the Croonian Lecture on ſome phyſiological reſearches, reſpecting the influence of the brain on the action of the heart, and on the generation of animal heat; Phil. Tranſ. 1811, p. 36.

And further experiments and obſervations on the influence of the brain in the generation of animal heat, Phil. Tranſ. 1812, p. 378.

On the ſubject of this article, the moſt valuable works, both for the collection of facts from various ſources, for original views and reſearches, acuteneſs of inveſtigation, and cloſe reaſoning, are thoſe of Mr. Ellis; entitled, "An Inquiry into the Changes induced on atmoſpheric Air by the Germination of Seeds, the Vegetation of Plants, and the Reſpiration of Animals," 1807. And, "Further Inquiries, &c." 1811. Dr. Boſtock's "Eſſay on Reſpiration," 1804, is a very valuable collection of the facts known on this ſubject up to that time. The preceding article is derived in greateſt part from theſe works. We may refer alſo to Thomſon's Syſtem of Chemiſtry, book 5. ch. 3. § 2; and Murray's Syſtem of Chemiſtry, book 9. ch. 2. § 1. To the valuable memoirs of Meſſrs. Allen and Pepys, "On the Changes produced in atmoſpheric Air and Oxygen Gas by Reſpiration," Phil. Tranſ. 1808; and "On Reſpiration," ibid. 1809. To thoſe of Lavoiſier in the Memoires de l'Academie des Sciences, 1777 and 1780; and in the Société Royale de Médécine, 1782—3. Of Lavoiſier and Seguin in the Mem. de l'Acad. 1789, 1790. See alſo Crawford, on Animal Heat; Goodwyn, on the Connection of Life with Reſpiration; Menzies, on Reſpiration; Coleman, on Suſpended Reſpiration; Davy's Reſearches; Spallanzani's Memoirs on Reſpiration, and his Rapports de l'Air avec les êtres Organiſés, t. 3. 8vo. Geneva. Prieſtley on Air. Seguin in Annales de Chimie, t. 5. and 21.

RESPITE, Respectus, in *Law*, &c. a delay, forbearance, or prolongation of time, granted any one for the payment of a debt or the like.

Menage derives the word *reſpite* from the Latin *reſpectus*; as *deſpite* from *deſpectus*. Du-Cange will rather have it come from *reſpirare, to breathe*; reſpite being, in effect, a breathing-while, granted a debtor, &c.

In the cuſtomary of Normandy, reſpite is a judicial delay or demur, given to procedures.

Respite, *Letters of*, or Credit. See Letters.

Respite *of Homage*, is a forbearance of the homage due from the vaſſal, or tenant, holding by homage, or by knight-ſervice, to his lord.

Anciently, thoſe who held by theſe tenures paid a ſmall ſum every fifth year into the exchequer, to be reſpited doing their homage or ſervice.

By ſtat. 12 Car. II. this reſpite of homage is taken away, as a charge ariſing from knight-ſervice; which is thereby likewiſe annulled.

Respite *of Execution*. See Reprieve.

Respite *of Jury*. See Jury.

RESPITED *on the Muſter-Roll, To be*, in *Military Language*, is to be ſuſpended from pay, &c.; during which period all advantages of promotion, pay, &c. are ſtopped. The money which is reſpited upon the muſter-roll is accounted for by the muſter-maſter general, and placed to the credit of the public by the paymaſter general.

RESPOND, in *Eccleſiaſtical Hiſtory*, was a ſhort anthem ſung after reading three or four verſes of a chapter: after which they proceeded with the chapter. Gibſon 263.

RESPONDEAS Ouster, in *Law*, is to anſwer over in an action to the merits of the caſe: or put in a more ſubſtantial plea.

RESPONDEAT Superior, a law phraſe. Where the ſheriffs are removable, as in London, for inſufficiency; *reſpondeat ſuperior*, that is, the mayor and commonalty are to anſwer for them.

If a coroner of a county is inſufficient, the county as his ſuperior ſhall anſwer for him. (Wood's Inſt. 83.) If a gaoler conftitutes another under him, and he permits an efcape, if he be not fufficient, *refpondeat fuperior;* and fuperior officers muft anfwer for their deputies in civil actions, if they are infufficient to anfwer damages.

For the infufficiency of a bailiff of a franchife *refpondeat fuperior,* that is, the lord of the franchife is to anfwer.

RESPONDENT, Respondens, in the fchools, a perfon who maintains a thefis in any art or fcience.

He is thus called, as being to anfwer all objections propofed by the opponent, or impugner, &c.

The refpondent's bufinefs is to fee whether the oppofition made by the contrary party be juft and legitimate; or whether fome of the laws and conditions of oppofition be not broken; which is called *ignoratio elenchi.* He is alfo to examine the moods and figures of the fyllogifms, to fee whether the premifes be juft, &c. and through the whole to anfwer rather by diftinguo's, than by direct negation.

Respondent, formed from the Latin *refpondere, to anfwer,* q. d. *pro alio fpondere, to promife for another,* in *Law,* a perfon who undertakes to anfwer for another; or binds himfelf as fecurity for the good behaviour of another.

The refpondent is to anfwer for the damages done by the perfon for whom he refponds. There are four ordonnances of the kings of France, by which the citizens are exprefsly forbid to take fervants without refpondents, bound in writing.

RESPONDENTIA, in *Commerce,* a term applied to money which is borrowed, not upon the veffel, as in bottomry, but upon the goods and merchandize contained in it, which muft neceffarily be fold or exchanged, in the courfe of a voyage; in which cafe the borrower, perfonally, is bound to anfwer the contract; and he is faid to take up money at refpondentia.

It is enacted, by ftat. 19 Geo. II. cap. 37, that all monies lent on bottomry, or refpondentia, on veffels bound to or from the Eaft Indies, fhall be exprefsly lent only upon the fhip, or upon the merchandize; that the lender fhall have the benefit of falvage; and that, if the borrower has not on board effects to the value of the fum borrowed, he fhall be refponfible to the lender for fo much of the principal as hath not been laid out, with legal intereft and all other charges, though the fhip and merchandize be totally loft.

Although refpondentia and bottomry are of themfelves a fpecies of infurance, yet the lender has an infurable intereft in his fecurities, and therefore may protect himfelf from the fea-rifk by infuring them. The lender can infure only the amount of the fum lent, and the borrower has an infurable intereft in the fhip or goods to the amount of the furplus value above the fum lent. If either were to infure more, it would be a gaming infurance, and void by the ftatute 19 Geo. II. c. 37, for all above the real intereft. But the ufage of trade may take a cafe out of this rule. Upon an infurance on goods, fpecie and effects in the India trade, the infured may recover for money laid out for the ufe of the fhip, and for which he charged refpondentia intereft, it being the ufage of trade to infure in this form. A policy on bottomry or refpondentia cannot be fubfcribed by the borrower of the money, becaufe it is only in confideration of the fea-rifk, from which he is exempt, that he agrees to pay the marine intereft. If he were to become an infurer, this would be no longer a loan upon bottomry, but a cloak for ufury. Refpondentia and bottomry fecurities, though they are the fubject of infurance, muft be particularly and fpecifically defcribed in the policy; for under the general denomination of goods, thefe fecurities cannot be infured. By 19 Geo. II. c. 32. if an under-writer become bankrupt before a lofs happen, the infured may claim; and after a lofs, prove his debt under the commiffion, and receive his dividend, as if the lofs had happened before the bankruptcy. See Bottomry.

RESPONSA Prudentum. See Civil and Response.

RESPONSALIS, in *Law,* he who appears for another in court at a day affigned.

Fleta makes this difference between *refponfalis atturnatus,* and *effoniator,* that the *effoniator* came only to allege the caufe of the party's abfence, be he demandant or tenant; whereas *refponfalis* came for the tenant not only to excufe his abfence, but to fignify what trial he means to undergo, the combat, or the country.

RESPONSARY Song, an anthem in which the chorifters fing by turns.

RESPONSE, Responsal, *Refponfatio,* an anfwer, reply, or repartee.

The word is chiefly ufed in fpeaking of the anfwers made to the prieft, by the people, in the litany, the pfalms, and other parts of the office.

It has its ufe, too, in fpeaking of the opinions or anfwers of the ancient jurifconfulti, when confulted on points of law.

The fifty books of the Digeft are compofed of *refponfa prudentum,* the refponfes of Papinian, Ulpian, Scævola, &c. collected by Juftinian; who afterwards gave them the force of laws. See Civil *Law.*

The refponfes of the emperors were more properly called *refcripts;* which fee.

RESPONSIONS, Responsiones, a term ufed in the *Military Orders,* for certain penfions or charges, which the knights, or the commandries they held, paid to the order.

Such a knight templar paid a refponfion of fifty pounds *per annum* to his order, on account of fuch a commandry.

In Rot. Parl. 9 Ric. II. the word is written *refponcies.*

RESPONSORIA, refponfes fung in chorus by the choir, in anfwer to the prieft in the cathedral fervice.

RESSAVA, in *Geography,* a town of European Turkey, in Servia; 46 miles S.E. of Belgrade.

RESSAULT, in *Architecture,* the effect of a body which either projects, or falls back, *i. e.* ftands either more out or in than another; fo as to be out of the line, or range, with it.

The term *reffault* is French, and but little ufed in Englifh; though the want of a word of equal import pleads for its naturalization.

RESSEL, or Roessel, in *Geography,* a town of Pruffia, in the province of Ermeland, with a caftle; 50 miles S. of Königfberg.

RESSELA, a term ufed by Paracelsus to fignify, as himfelf explains it, any thing that expels heat, in oppofition to *affa,* which with him fignifies any thing that promotes it.

RESSONS, in *Geography,* a town of France, in the department of the Oife, and chief place of a canton, in the diftrict of Compiègne; 10 miles W.S.W. of Noyons. The place contains 1039, and the canton 9637 inhabitants, on a territory of 170 kiliometres, in 23 communes.

RESSORT, or Resort, a term purely French, yet frequently ufed, by our late writers, to fignify the jurifdiction or authority of a court.

The word, in its popular meaning, fignifies *fpring,* or the force of elafticity. Hence it is alfo ufed for a jurifdiction, and the extent or diftrict thereof; as when we fay, fuch a thing belongs to his reffort; a judge out of his reffort has no authority. But its chief ufe among us is in fpeaking of a court or tribunal, where appeals are judged; or of a court or perfon who judges finally and ultimately, and whence there is no appeal.

The

The houſe of lords judge in the laſt reſſort, *en dernier reſſort.* Preſidials judge in the laſt reſſort of all criminals proſecuted by the provoſts of the marſhals. See Dernier *reſſort.*

Ressort, or *Reſort,* is alſo uſed in a writ of ayel, or couſenage, in the ſame ſenſe as *deſcent,* in a writ of right.

RESSOURCE, or Resource, a term purely French, yet uſed by Engliſh writers to denote a means or foundation of a man's recovering himſelf from his fall or ruin; or an after-game for the repairing of his damages.

Skinner derives the word from the French *reſoudre, to reſolve.* A reſource ſtrictly and literally expreſſes a means which preſents itſelf afreſh.

This merchant has credit and friends ſtill left; he has great reſources.

REST, Quies, in *Phyſics,* the continuance of a body in the ſame place; or its continual application or contiguity to the ſame parts of the ambient and contiguous bodies. See Space.

Reſt is either *abſolute* or *relative,* as place is. See Place.

Some define reſt the ſtate of a thing without motion; and hence again reſt becomes either abſolute or relative, as motion is. See Motion.

Sir Iſaac Newton defines true or *abſolute* reſt to be the continuance of a body in the ſame part of abſolute and immoveable ſpace; and *relative* reſt to be the continuance of a body in the ſame part of relative ſpace.

Thus, in a ſhip under ſail, relative reſt is the continuance of a body in the ſame region of the ſhip, or the ſame part of its cavity. True or abſolute reſt is its continuance in the ſame part of univerſal ſpace, in which the ſhip, with its cavity and contents, are all contained.

Hence, if the earth be really and abſolutely at reſt, the body relatively at reſt in the ſhip will really and abſolutely move, and that with the velocity with which the veſſel moves. But if the earth do likewiſe move, there will then ariſe a real and abſolute motion of the body at reſt; partly from the real motion of the earth in abſolute ſpace, and partly from the relative motion of the ſhip on the ſea. Laſtly, if the body be likewiſe relatively moved in the ſhip, its real motion will ariſe partly from the real motion of the earth in immoveable ſpace, and partly from the relative motion of the ſhip on the ſea, and of the body in the ſhip.

Thus, if that part of the earth, where the ſhip is, move eaſtward with a velocity of 10,010 parts, and the veſſel be carried by the wind weſtward ten parts, and, at the ſame time, a ſeaman aboard walk with the velocity of one part, the ſeaman will be moved really and abſolutely in immoveable ſpace eaſtward, with 10,001 parts of velocity; and relatively on the earth, with nine parts of velocity weſtwards.

It is an axiom in philoſophy, that matter is indifferent as to reſt or motion. Hence ſir Iſaac Newton lays it down as a law of Nature, that every body perſeveres in its ſtate, either of reſt or uniform motion, except ſo far as it is diſturbed by external cauſes.

The Carteſians will have firmneſs, hardneſs, or ſolidity of bodies to conſiſt in this, that their parts are at reſt with regard to each other; and this reſt they eſtabliſh as the great nexus, or principle of coheſion, by which the parts are connected together.

Fluidity, they add, conſiſts in a perpetual motion of the parts, &c. But the Newtonian philoſophy furniſhes us with much better ſolutions. See Solidity, Fluidity, and Cohesion.

Monſieur de Maupertuis aſſerts, that when bodies are in equilibrio, they muſt be ſo ſituated, that, if any ſmall motion be impreſſed on them, the quantity of action reſulting will be the leaſt poſſible. This he calls the law of reſt, and from this law he deduces the fundamental propoſition of ſtatics. See Mem. de l'Acad. de Berlin, tom. ii. p. 294.

Monſieur de Maupertuis deduces the laws of percuſſion from the ſame principle. See *Quantity of* Action.

Rest, *Repoſe,* or *Pauſe,* in *Poetry,* is uſed for the cæſura, which, in Alexandrine verſes, falls on the ſixth ſyllable; and, in verſes of ten or eleven ſyllables, on the fourth.

The reſt ſhould never fall on a monoſyllable, on which the voice may not dwell: it is called reſt, becauſe the ear and the pronunciation have both a repoſe, or reſpite.

Rest, in *Military Language,* a kind of fork to ſupport muſkets, when preſented in order to fire. Sometimes theſe reſts were armed with a contrivance called a ſwine's feather, which was a ſort of ſword-blade, or tuck, that iſſued from the ſtaff of the reſt, at the head: this, being placed before the muſqueteers when loading, ſerved, like the ſtakes placed before the archers, to keep off the cavalry. See Musket.

Reſts were of different lengths, according to the heights of the men who were to uſe them; they were ſhod with ſharp iron ferrils, for ſticking them into the ground, and were, on the march, when the muſket was ſhouldered, carried in the right hand, or hung upon it, by means of a ſtring or loop tied under the head.

Rest *Arms, To,* is to bring the firelock to the ſame poſition as in preſent arms.

To Rest *upon reverſed Arms.* At military funerals the arms are reverſed: on which occaſions, the ſoldiers belonging to the firing party, reſt upon the butt ends of their firelocks, while the funeral ſervice is performed, leaning with their cheeks ſo as to turn from the corpſe; and the word of command is "Reſt upon your arms reverſed."

Rest, in *Tilting Armour.* See Tilting *Armour.*

Rest, in *Muſic,* is a pauſe, or interval of time, during which there is an intermiſſion of the voice, or ſound.

Reſts are ſometimes uſed in melody, that is, in muſic of a ſingle part, to expreſs ſome ſimple paſſion, or even for variety ſake; but more frequently in harmony, or compoſitions of ſeveral parts, for the ſake of the pleaſure of hearing one part move on while another reſts, and this interchangeably.

Reſts are either for a whole bar, or more than a bar, or but for a part of a bar. When the reſt is for a part, it is expreſſed by certain ſigns, correſponding to the quantity of certain notes of time; as minim, crotchet, &c.; and is accordingly called *minim-reſt, crotchet-reſt,* &c.

The characters or figures of which, ſee under Characters *of Muſic,* where the notes and correſponding reſts are found together.

When any one of thoſe characters occurs, either on a line or ſpace, that part is always ſilent for the time of a minim, or crotchet, &c. Sometimes a reſt is for a crotchet and quaver together, or for other quantities of time for which there is no particular note; in which caſe the ſigns of ſilence are not reſts, but ſuch ſilence is expreſſed by placing together as many reſts, of different time, as make up the deſigned reſt. When the reſt is for a whole bar, the ſemibreve reſt is always uſed. If the reſt be for two meaſures, it is marked by a line drawn acroſs a whole ſpace. For three meaſures it is drawn acroſs a ſpace and a half, and, for four meaſures, acroſs two ſpaces. But, to prevent ambiguity, the number of bars is uſually written over the ſign.

Some of the more ancient writers in muſic make theſe reſts of different value in different ſpecies of time, *e. gr.* the character of a minim-reſt, in common time, ſay they, expreſſes the reſt of three crotchets in triple time; in that of the

the triples $\frac{6}{8}$, $\frac{6}{6}$, $\frac{12}{8}$, $\frac{12}{16}$, it always marks a half-meaſure, how different ſoever theſe may be among themſelves.

They add, that the reſt of a crotchet in common time is a reſt of three quavers in the triple $\frac{9}{8}$, and that the quaver-reſt of common time is equal to three ſemiquavers in the triple $\frac{9}{16}$. But this variety in the uſe of the ſame character is now laid aſide. Malcolm's Treat. of Muſic, p. 409, &c.

Franco, the inventor of muſical characters for time, commonly aſcribed to John de Muris, in the fourth chapter of his tract in the Bodleian library, entitled "Ars Cantus Menſurabilis," ſays, "as the ſounds in each mood are expreſſed by different notes or figures, and as diſcant itſelf is as much regulated by *ſilence* as by ſound, it will be neceſſary to treat not only of the ſigns or repreſentatives of ſounds, but of their equivalent reſts or pauſes."

But though Magiſter Franco may have invented the firſt time-table, conſiſting of full or black notes; John de Muris ſeems to have arranged the ſecond time-table, conſiſting of void or open notes, from the maxima to the minim. And in Morley's time, the notes were multiplied and accelerated to the ſemiquaver, with their equivalent reſts. See the *third* TIME-TABLE.

REST-*Harrow*, in *Botany*. See ONONIS.

RESTAUR, RESTOR, in *Ancient Cuſtoms*, the remedy or recourſe which aſſurers have againſt each other, according to the date of their aſſurances; or againſt the maſters, if the average ariſe through their default; as through ill loading, want of caulking, or want of having the veſſel tight.

The word is alſo uſed for the remedy, or recourſe, a perſon has againſt his guarantee, or other perſon, who is to indemnify him from any damage ſuſtained. Hence *reſtaurant* and *reſtauration*. In the lower Latin they alſo uſe the words *reſtor* and *reſtaur*.

RESTAURATION, RESTAURATIO, *Reſtoration*, the act of re-eſtabliſhing, or ſetting a thing in its former good eſtate.

Thus we ſay, the reſtauration of a minor to the poſſeſſion of his effects, alienated in the time of his minority. In the French laws it is an ancient formula, uſed for the reſtoring a perſon to his good name, after he has been wrongfully accuſed and condemned.

In England we ſay *the Reſtauration* or *Reſtoration*, by way of eminence, for the return of king Charles II. in 1660, after the civil wars.

The 29th of May is an anniverſary feſtival, appointed to be held in commemoration of the reſtoration of regal and epiſcopal government, by ſtat. 12 Car. II. c. 14.

We ſhall here obſerve, that the form of prayer for the 29th of May, as well as for the 30th of January, were of a different complexion in the reign of king Charles II. from the preſent, of which the reaſon is ſaid to be this: the parliament and other leading men, who were active in his reſtoration, and who had been concerned in oppoſing his father's meaſures, would not be called traitors; and required that a diſtinction ſhould be made between the commencement of the war and the concluſion of it; they would not ſuffer the firſt oppoſition made to the meaſures of that unhappy prince to be ſtyled rebellion, though they diſapproved of the abolition of regal government which enſued.

And accordingly the offices for theſe two ſolemnities were drawn up, without any reflection on the firſt authors or promoters of the oppoſition, and, in general, breathe more a ſpirit of piety than of party, of humiliation than of revenge; and, throughout, are modeſt, grave, decent, ſenſible, and devout. King James II. altered theſe forms, and king William did not venture to reduce them to their primitive ſtate; and ſo they have continued, with very little variation, to this day.

There is no order in either of theſe offices for a ſermon or homily on this day; and in the office of Charles II., there is no direction for a ſermon or homily on the 30th of January: but by the office of James II. it is required that on the ſaid 30th day of January ſhall be read the firſt and ſecond parts of the homily againſt diſobedience and wilful rebellion, or elſe the miniſter ſhall preach a ſermon of his own compoſing upon the ſame argument. The 29th of May is not a holiday in any of the law-offices, and conſequently no officer can take an extraordinary fee for buſineſs done on that day. 7 Term Rep. 163.

By 12 Car. II. c. 14. it is enacted, to the end that all perſons may be reminded of their duty on the 29th of May, and be the better prepared to diſcharge the ſame with that piety and devotion which become them, that every miniſter ſhall give notice to his pariſhioners publicly in the church at morning prayer, the Lord's day next before ſuch 29th day of May, for the due obſervation of the ſaid day, and ſhall then likewiſe publicly and diſtinctly read this preſent act to the people.

RESTAURATION, in *Architecture*, the act of repairing all the parts of a building gone to decay, either through the courſe of time, or other injuries; in ſuch manner, as that it is not only re-eſtabliſhed in its firſt form, but conſiderably augmented.

It is evident, from the plinths of the Corinthian columns of the Pantheon (which are almoſt wholly under ground), that the pavement of this temple is only a reſtauration made in the time of Septimius Severus. Daviler.

The temple of Concord, behind the Capitol at Rome, having been burnt long after it was built, and having angular baſes different from the reſt, ſeems to have been reſtored from the ruins of ſeveral ancient buildings.

RESTAURATION, in *Sculpture*, is the repairing of a mutilated ſtatue, &c. See REPAIRING.

Moſt of the antique ſtatues have undergone a reſtauration; as the Farneſe Hercules, the Faunus in the Villa Borgheſe at Rome, the Wreſtlers in the gallery of the great duke of Florence, the Venus of Arles, in the gallery at Verſailles. But theſe reſtaurations have all been made by the ableſt ſculptors. Daviler.

RESTIACEÆ, in *Botany*, a natural order of plants, firſt ſeparated from the *Junci* of Juſſieu by Mr. Brown, Prodr. Nov. Holl. v. 1. 243, and named from one of its chief genera; ſee RESTIO. The characters are theſe.

Perianth unconnected, deeply divided into from two to ſix ſegments, or rather of ſo many leaves; rarely wanting. *Corolla* none. *Stamens* definite, from one to ſix; when they are two or three, in a four or ſix-cleft perianth, they are oppoſite to its inner leaves. *Germen* of one or ſeveral cells, each cell containing one pendulous ſeed, except in *Xyris*, whoſe ſeeds are numerous. *Pericarp* either capſular, or amentaceous. *Seeds* inverted. *Albumen* ſhaped like the ſeed. *Embryo* lenticular, ſituated in the lower end of the ſeed, oppoſite to its ſcar, at the outſide of the albumen.

Plants herbaceous or ſomewhat ſhrubby, almoſt all exotic with reſpect to Britain, and even Europe. *Leaves* ſimple, narrow, in ſome caſes wanting. *Stems* naked, but often furniſhed with ſheathing ſcales, cloven at one ſide, imbricated, or equitant, at the other. *Flowers* for the moſt part aggregate, ſpiked or capitate, ſeparated by *bracteas*, the *ſtamens* and *ſtyles* generally in ſeparate individuals.

This order is diſtinguiſhed from the *Junci*, by having the embryo external, and contrary to the ſcar; from the *Commelineæ* of Brown, by the figure of that part, and its not being

being enclofed in the albumen. Thofe genera which have the habit of the *Cyperaceous* order, are well diftinguifhed from it by the fheaths of the ftem being fplit, not undivided. *Xyris*, though referred to the *Reftiaceæ*, and fcarcely more akin to any other tribe, ftill differs widely from the reft of this order; efpecially in the petal-like inner fegments, or leaves, of its perianth; the claws bearing the ftamens at their fummits; and the numerous feeds. See Obfervations on the generic character of Restio.

The New Holland genera of the prefent order are *Reftio*, *Lepyrodia*, *Lyginia*, *Anarthria*, *Loxocarya*, *Leptocarpus*, *Chætanthus*, *Hypolæna*, *Aphelia*, *Devauxia*, *Alepyrum*, *Eriocaulon* and *Xyris*.

RESTIARIA, a name given by Rumphius, in his Herbarium Amboinenfe, v. 3. 187, to two or three different fhrubs, on account of their fitnefs for ropes, or cordage; *reftiarius* being a fort of bafe Latin word for a rope-maker. The firft of thefe, *R. alba*, t. 119, is a very well-marked genus, for which the name might have been retained; but Linnæus, in his Supplementum, has called that genus *Commerfonia*, after the example of Forfter, in his Nova Genera t. 22. (See Commersonia.) Of the fecond, termed *R. nigra*, Rumphius gives no plate. We fhall fpeak of it prefently. The third he has called *Perticaria*, from *pertica*, a ftaff or pole; which name is alfo a fynonym of the other two. Nothing is known refpecting the flowers, or generic character, of this laft. Loureiro has adopted the name *Reftiaria*, for a plant which he fuppofes the fame with the *nigra* of Rumphius, but of which he knew the female flowers only. The following is his account of it. Loureir. Cochinch. 639. Clafs, *Diœcia;* Order unknown, as well as the Nat. Ord.

Gen. Ch. Male flowers unknown.

Female on a feparate plant. *Cal.* Perianth fuperior, oblong, capfular; limb in five deep, lanceolate, fpreading fegments. *Cor.* none. *Pift.* Germen inferior, oblong; ftyle none; ftigma concave. *Peric.* Capfule calycine, ovate-oblong, fomewhat tapering at each end, five-ribbed, hairy, with two cells and two valves. *Seeds* numerous, compreffed, roundifh, with a long, thin, membranous, linear wing at each fide.

Eff. Ch. Male . . . .

Female, Calyx five-cleft, capfular, fuperior. Corolla none. Stigma concave. Capfule with five ribs, two cells, two valves, and numerous winged feeds.

Obf. We do not profefs to underftand Loureiro's expreffions of *perianthium capfulare*, and *capfula calycina*, but give them as we find them, having no knowledge of the plant itfelf. De Theis fuggefts its affinity to *Gouania*.

1. R. *cordata*. Lour. (R. nigra; Rumph. Amb. v. 3. 188?)—Native of the woods of Cochinchina. A large *fhrub*, with a reclining *ftem*, and climbing *branches*, deftitute of tendrils or thorns. *Leaves* oppofite, heart-fhaped, rugofe, hairy, entire, large. *Flowers* in lax, axillary *panicles*, with long general as well as partial ftalks. The *bark* is tough and porous, fplitting into long ftrips, of which torches are made, and which ferve alfo for caulking of veffels. The generic name was adopted by Loureiro, becaufe of the fitnefs of the ftems and branches for cordage.

RESTINCLIERS, in *Geography*, a town of France, in the department of the Herault; nine miles N.E. of Montpelier.

RESTINCTION, Restinctio, in *Chemiftry*, the quenching of a metal or mineral in fome liquor, in order either to correct or to exalt it; by giving it fome new quality, power, &c.

RESTING Ground, in *Gardening*, the means of refreshing it, and of reftoring its fertility by the omiffion of culinary crops, and the cultivation of fuch as have this tendency, or by any other methods which may have the fame effect. It is a fort of management which is principally accomplifhed in two different ways; the former of which is that of fowing a certain portion of it, annually, with corn and fome fort of grafs feeds, fuffering it to continue under the latter of them for three or more years, as in arable field lands, in order that it may then be broken up again. This is a very beneficial method, but not much practifed, except by market-gardeners, who employ thefe two crops in feeding and foddering their cattle. When made ufe of in other ways, as in other gardens, great care fhould be taken that the grafs never runs up to feed, as is fometimes the cafe in market-gardens, but in all other particulars the practice may be entirely the fame. In this way of proceeding, by fowing and laying down a certain quantity of ground every year, the fame extent may be broken up, which will, of courfe, afford fo much frefh foil annually, upon which fuch garden crops as anfwer beft on newly broken up land, may be put in and raifed, as thofe of onions, carrots, turnips, and a great many other kinds.

The latter of the above modes of managing the bufinefs, is, however, better adapted to gardens in general, as being more fuited to the nature of their culture. It was, probably, firft fuggefted by the author of the "Scotch Forcing Gardener;" and is extremely well fuited to produce the fame effects and advantages as that which has been already noticed; and it may, indeed, in fome cafes, be combined with it, or ufed conjointly, with great benefit; as by fuch means much frefh furface foil will be yearly at the command of the gardener. The manner of performing it is this; after taking three culinary crops off from the firft furface, the ground is to be trenched over three fpits deep, by which the bottom and top parts are reverfed, and the middle part ftill remains in that fituation; then three fimilar crops are to be taken off from this furface, and the ground afterwards trenched two fpits deep, by which means the top becomes the middle, and the middle the top; three of the fame kind of crops being here alfo taken off from this furface, and then the ground trenched three fpits again, that part which was laft the middle, and now the top, becomes the bottom; and that which is now the bottom, and was the furface at firft, now becomes the furface again, after having had fix years' reft. By this alternate manner of proceeding, one time trenching three fpits deep, and the other two, the furface will conftantly be changed, and will reft fix years, while it is three years productive. On which account there will be continually new ground and foil in the garden for the growth of healthy culinary vegetables; and befides, much lefs manure will be wanted than where the foil is fhallow, and the fame furface conftantly under culinary crops.

Proper and careful modes of cropping, as well as other kinds of management, may likewife, in many cafes, contribute greatly to the fame intention.

Resting *Land*, in *Agriculture*, the means of keeping it without any fort of crop, or only under particular kinds, in the view of reftoring its fertility. This is done in the practice of naked fallowing, as well as that of cultivating green crops by way of a fallow, and by laying land down to the ftate of grafs, in order to its being afterwards broken up for grain crops. See Fallow and Fallowing, alfo Green *Crops*, and Laying *down to grafs*.

RESTIO, in *Botany*, from *reftis*, a cord, becaufe many of the genus ferve, at the Cape of Good Hope, where they abound, to make ropes, bafkets, &c. *Reftio* is properly a perfon who fells cord, or ropes. Elegia, fee that article, is is nearly related in habit, as well as characters, to the prefent genus, and was finally united to it by Linnæus, contrary to Thunberg's opinion.—Linn. Syft. Nat. ed. 12. v. 2. 735. Schreb. 676. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 368. Brown Prodr. Nov. Holl. v. 1. 244. Thunb. Diff. May 17. 1788. Rottb. Gram. 1. Juff. 44. Labill. Nov. Holl. v. 2. 77. Lamarck Illuftr. t. 804. (Chondropetalum; Rottb. Gram. 10. Calorophus; Labill. Nov. Holl. v. 2. 78.)—Clafs and order, *Dioecia Triandria*. Nat. Ord. *Calamariæ*, Linn. *Junci*, Juff. *Reftiaceæ*, Brown.

Gen. Ch. Male, *Cal.* Catkin ovate or oblong, many-flowered; its fcales coriaceous, imbricated, keeled. Perianth compreffed, of four or fix, nearly equal leaves; two of the outer ones boat-like, the third flat; the three innermoft lanceolate, thinner, one of them broader than the reft. *Cor.* none, except the three inner leaves of the calyx be fo confidered. *Stam.* Filaments three, fometimes but two; anthers oblong, fimple, peltate.

Female, on a feparate plant, *Cal.* and *Cor.* as in the male. *Pift.* Germen fuperior, triangular; ftyle one, deeply divided into two or three parts; ftigmas feathery. *Peric.* Capfule with two or three lobes, and as many cells, burfting at the prominent angles. *Seeds* folitary, fomewhat oval.

Obf. *Chondropetalum* of Rottboll differs from the reft of the fpecies, in having the inner fegments of the calyx longer, and of a cartilaginous texture. This difference, and the ftill more remarkable one in *Xyris*, between the outer and inner fegments of the calyx, might furely authorize us to call the three latter a corolla, in both thefe inftances.

Eff. Ch. Male, Catkin imbricated. Perianth of four or fix leaves, fhorter than the fcales of the catkin, deftitute of internal fcales. Corolla none. Anthers peltate.

Female, Catkin and Perianth like the male. Stigmas two or three. Capfule of two or three lobes, and as many cells, burfting at the angles. Seeds folitary.

The plants of this genus have a hard, rigid, fmooth, rufhy habit. The *root* is fcaly, creeping, and perennial. *Stems* rufhy, fimple or branched, leaflefs, fheathed with fcales fplit at one fide. *Catkins* either folitary, fpiked or panicled. Mr. Brown obferves, that the fcar of the *feed* is naked in the New Holland fpecies, but in thofe from the Cape of Good Hope it is bordered. Several things which Thunberg and Rottboll have referred to *Reftio*, are by Mr. Brown removed to other genera; fee Leptocarpus and Thamnochortus. This author defines 24 New Holland fpecies, in his Prodromus. How many are found at the Cape, we have no means of determining, becaufe of the uncertainties refpecting their generic characters, which we have not materials to remove. The following may ferve as examples.

Section 1. *Stem fimple.*

R. *tectorum.* Thatch Rope-grafs. Linn. Suppl. 425. Ait. n. 1. (Chondropetalum deuftum; Rottb. Gram. 10. t. 3. f. 2.)—Stem fimple. Leaves none. Catkins racemofe, moftly leaning one way, drooping, bracteated, roundifh, triangular. Gathered by Thunberg at the Cape, from whence Mr. Maffon fent living plants to Kew, in 1793. They are kept in the greenhoufe, bloffoming in May and June. The *root* is perennial, fmall and tapering, throwing out horizontal fcaly fhoots. *Stems* feveral, a foot and half high, erect, very ftraight, round, flender, fmooth, unbranched, with fhort taper-pointed fheaths at the joints. *Clufter* terminal, compound, about two inches long, variegated with black, or dark purple, and brown. The ftems are ufed for thatching, for which their hard rigid nature is well calculated; nor is this thatch difturbed by the very high winds that prevail in fouthern Africa. *Thunberg.*

R. *cernuus.* Pendulous-headed Rope-grafs. Linn. Suppl. 425. Thunb. Reft. n. 4. t. 1. f. 2.—Stem fimple. Leaves none. Catkins turbinate, pendulous, on capillary ftalks. Native of the Cape, on hills about the Table mountain. The *ftem* is flender, jointed and fmooth, two feet high, or more, with fcales at the joints, but no leaves. *Catkins* three, four, or five, at the top of each ftem, about the fize of a pea, brown, obtufe, tapering at the bafe, pendulous, each fupported by a capillary ftalk. *Scales* obtufe, with a fmall point.

R. *dichotomus.* Fork-leaved Rope-grafs. Linn. Syft. Nat. ed. 12. v. 2. 735. Rottb. Gram. 2. t. 1. f. 1. (Schœnus capenfis; Linn. Sp. Pl. 64?)—Stems fimple. Leaves repeatedly compound, with awl-fhaped leaflets. Panicle drooping. Catkins oblong. Scales taper-pointed. Common at the Cape. *Stems* feveral, a foot or more in height, bearing a few fheaths. *Leaves*, or, as fome call them, barren ftems, much fhorter than the flowering ftems, flender, twifted, branched, with a fheath at each joint; their ultimate fubdivifions awl-fhaped, channelled. *Panicles* at the top of each ftem, of 10 or 12 drooping oblong *catkins*, whofe fcales are of a fhining brown, and very finely pointed.

Section 2. *Stem branched.*

R. *verticillaris.* Horfe-tail Rope-grafs. Linn. Suppl. 425. Thunb. Reft. n. 22. t. 1. f. 7.—Branches whorled, jointed; with ovate fcales. Panicle compound, clofe.—Found about the banks of rivers at the Cape. *Stem* five or fix feet high, refembling an *Equifetum* in its copious, flender, whorled branches, from every joint; bearing numerous ovate, taper-pointed, fmall fcales. We confefs ourfelves unable to draw a line between thefe branches, and what we have termed leaves in the laft-defcribed fpecies, except that the latter are moftly, if not entirely, radical, and thefe grow from every joint of the ftem. The *catkins* are extremely fmall and numerous, in branched, repeatedly compound, denfe clufters.

R. *tetraphyllus.* Four-leaved Rope-grafs. Labill. Nov. Holl. v. 2. 77. t. 226, 227. Brown n. 24.—Stems femicylindrical, with blunt fheaths. Leaflets fetaceous. Panicle terminal, compound. Catkins nearly globofe. Scales pointed. Male flowers fix-cleft; female four-cleft.—Native of New South Wales and Van Diemen's ifland. *Stems* numerous, ftout, three feet high, with a few leafy branches in the upper part, whofe ultimate divifions are briftle-fhaped. *Catkins* ftalked, ovate in the female plant, nearly globofe in the male. The perianth of the female flowers has but four leaves, that of the male fix.

RESTITUTION, Restitutio, in *Phyfics*, the returning of elaftic bodies forcibly bent to their natural ftate, by fome called the *motion of reftitution.* See Elasticity.

Contraction being the proper and natural action of mufcular fibres, fome authors afcribe dilatation to a motion of reftitution; but the expreffion, as well as the idea, is very faulty.

Restitution, in the moral and legal fenfe, is the act of reftoring a perfon to his right, or of returning fomething unjuftly taken or detained from him.

Reftitution is reducible to commutative juftice; and till it be made, the cafuifts determine the party all the while guilty of theft.

The illegal incumbents of benefices are condemned to a reftitution of the fruits of the benefices. In the Romifh church, ufurers, &c. are obliged to a reftitution of their ill-gotten goods; otherwife the prieft has no authority to give them abfolution.

Restitution *in Blood.* See Corruption *of Blood*, Attainder, and Pardon.

Resti-

Restitution *of Conjugal Rights*. See Conjugal *Rights*.

Restitution *of Stolen Goods*, in *Law*, is allowed to the profecutor, on a conviction of larciny, by ftat. 21 Hen. VIII. c. 11. For, by the common law, there was no reftitution of goods upon an indictment, becaufe it is at the fuit of the king only; and therefore the party was forced to bring an appeal of robbery, in order to have his goods again. But it being confidered that the party, profecuting the offender by indictment, deferves as much encouragement as he who profecutes by appeal, this ftatute was made, which enacts, that if any perfon be convicted of larciny by the evidence of the party robbed, he fhall have full reftitution of his money, goods, and chattels, or the value of them out of the offender's goods, if he has any, by a writ to be granted by the juftices. And this writ of reftitution fhall reach the goods fo ftolen, notwithftanding the property of them is endeavoured to be altered by fale in market overt; or elfe, without fuch writ of reftitution, the party may peaceably retake his goods, wherever he happens to find them, unlefs a new property be fairly acquired therein; or, laftly, if the felon be convicted and pardoned, or be allowed his clergy, the party robbed may bring his action of trover againft him for his goods, and recover a fatisfaction in damages; but fuch action lies not before profecution, for fo felonies would be made up and healed. See Recaption.

Restitution *of Temporalities of Bifhops*. See Temporalities, and Restitutione *Temporalium*.

Restitution *in Integrum*, is ufed for what is otherwife called *refciffion*.

Religious obtain reftitution againft their vows, *i. e.* they are freed from their obligation, when they proteft againft them within five years of their profeffion.

In the hiftory of Germany for the feventeenth century, the firft day of January, 1624, is called the *term of reftitution;* becaufe by the peace of Munfter, then concluded, the Lutheran and Calvinift princes were obliged to reftitute, or reftore what they had taken from the Roman Catholic churches in their territories till that day.

By the peace of Weftphalia in 1648, the reftitution-edict was abrogated, and both the contending parties confirmed in the perpetual and uninterrupted poffeffion of whatever they had occupied in the beginning of the year 1624. And all the articles agreed upon by this peace were confirmed and ratified, in the year 1650, at Nuremberg.

Restitution *of Medals*, or *Reftituted Medals*, is a phrafe ufed by antiquaries, for fuch medals as were ftruck by the emperors, to renew or retrieve the memory of their predeceffors.

Hence it is, that in feveral medals we find the letters rest. Claudius was the firft who began this practice, by ftriking afrefh feveral medals of Auguftus. Nero did the fame; and Titus, after the example of his father, ftruck reftitutions of moft of his predeceffors. Some, however, have maintained that the reftituted medals of Claudius and Nero are modern and fpurious, and that the practice began under Titus.

Gallienus ftruck a general reftitution of moft of the preceding emperors in two medals, the one bearing an altar, the other an eagle, without the *reft*. F. Joubert choofes rather to call them *converfations* than reftitutions, as being done quite anew. Thefe were defigned to preferve the remembrance of the confecration of thofe emperors in honour of whom they were ftruck; and they have all the fame legend on the reverfe, *viz.* consecratio.

RESTITUTIONE *extracti ab ecclefia*, in *Law*, a writ anciently granted for the reftoring a man to the church, or fanctuary, from which he had been forced way.

Restitutione *Temporalium*, a writ which lies where a man is elected and confirmed bifhop of a diocefe, for the recovery of the temporalities, or barony, of the faid bifhopric.

It is directed from the king to the efcheator, or rather fheriff of the county.

RESTIVE, or Resty, a term applied to a horfe, &c. that ftops, or runs back, inftead of advancing forwards.

In the manege, a reftive horfe is a rebellious, refractory, ill-broken horfe, which only goes where it will, and when it will. The word is formed from the Latin *reftivus*, which fignifies the fame thing. (See Ramingue.) A horfe of this fort, who has been too much conftrained and tyrannized over, fhould be treated with the fame lenity as a young colt. The fpurs are improper to be ufed to either; inftead of which a fwitch fhould be ufed, in order to drive him forward, as he will be thus lefs alarmed; becaufe the fpurs furprife a horfe, abate his courage, and are more likely to make him reftive than oblige him to go forward, if he refufes to do fo. There is likewife another method to punifh a reftive horfe, which is to make him go backward the moment he begins to refift. Thefe corrections generally fucceed; but the general rule is to pufh and carry your horfe forward, whenever he refufes to advance, and continues in the fame place, and defends himfelf either by turning or flinging his croupe on one fide or the other; and, for this purpofe, nothing is fo efficacious as to pufh him forward vigoroufly. Berenger's Horfemanfhip, vol. ii. p. 29, &c. See Ride.

RESTOR. See Restaur.

RESTORATION. See Restauration.

Restoration, in *Theology*, a term applied by thofe who maintain the doctrine of the final happinefs of all mankind, to the recovery of tranfgreffors from a ftate of guilt and mifery to pardon and felicity, in confequence of the penal difcipline which they are doomed to endure in a future world. See this doctrine difcuffed under the article Hell.

Restoration *Cove*, in *Geography*, a bay on the weft coaft of North America, in Burke's canal, fo called by Vancouver, from the 29th of May, the day of its difcovery. Among the fkins brought to fale at this bay were thofe of the animal which produces the wool, of which the garments worn by fome of the Indians are made. Their length, exclufively of the head and tail, was 50 inches; and their breadth, exclufively of the legs, was 36 inches. All the fkins that were brought to captain Vancouver were white, or rather of a cream colour. The pelt was thick, and of a fine texture; but from their ftate of mutilation, the fpecies of animals to which they belonged could not be afcertained. The women, who appeared to be of the greateft importance, were adorned by an horizontal incifion about three-tenths of an inch below the upper part of the under lip, extending from one corner of the mouth to the other; and in this flit was fixed a piece of wood, confined clofely to the gums of the lower jaw, and projecting by its external furface horizontally. Thefe wooden ornaments were of an oval form, and refembled a fmall oval platter or difh, concave on both fides: the fmalleft of them was about $2\frac{1}{2}$ inches, and the largeft $3\frac{1}{10}$ inches long, and $1\frac{1}{2}$ inch broad; the others decreafed in breadth in proportion to their length. The clothing of the natives here confifted either of the fkins of the fea-otter, or of garments made of the pine-bark, into which was neatly wrought fome of the fur of the fea-otter, and their fides and bottoms were decorated with various colours. In this they ufe only woollen yarn, very fine, well fpun, and dyed for that purpofe, particularly with a very

lively

lively and beautiful yellow. N. lat. 52° 1′. E. long. 232° 20′.

Restoration *Island*, a small island in the South Pacific ocean, near the east coast of New Holland, discovered by captain Bligh in 1789. S. lat. 12° 39′.

Restoration *Point*, a cape on the west coast of Vashon's island. N. lat. 47° 30′. E. long. 237° 46′.

RESTORATIVE, in *Medicine*, such substances both in the way of food, drink, and medicines, which are calculated to restore the vigour of the constitution, after the cessation of acute diseases, after violent hæmorrhages, fatigue, watching, or want of food. These of course comprehend the most nutritious parts of animal substances, jellies, broths, &c.; and the vegetable starches, arrow-root, sago, &c. with milk, rice, and other light nourishment. The restorative medicines will be selected from the bitter and aromatic vegetables, and some of the metallic salts, especially those of iron; their principal use being to give tone and vigour to the digestive organs, and thus enable them to extract and digest the nutriment, which the food affords.

RESTOUN, in *Geography*, a town of Syria, anciently called "Arethusa;" 12 miles S.E. of Hamah.

RESTOW, a town of Austrian Poland, in Galicia; 72 miles W. of Lemberg.

RESTRAINING Statute. See Remedial.

Restraining *Statute of Leases*. See Leases *by Statute*.

RESTRAINT is when an action is hindered, or stopped, contrary to volition, or the preference of the mind.

RESTRICTION, the act of modifying, limiting, or restraining a thing to narrower bounds.

General laws always bear some restriction. In contracts it is usual to have *restrictive clauses*, which bind the covenants down to certain bounds.

Restriction, *Mental*. See Reservation.

Restriction, among *Logicians*, is understood of the limiting a term, so as to make it signify less than it usually does.

In which sense the name philosopher is restrained to Aristotle; Great, to Alexander; City, to Rome, &c.

RESTRICTIVE Proposition. See Proposition.

Restrictive *Suture*. See Suture.

RESTRINGENT, in *Medicine*. See Astringent.

RESTY. See Restive and Ride.

RESULT, what is gathered from a conference, an inquiry, meditation, discourse, or the like; or the conclusion and effect thereof.

The usual result of disputes, Mr. Bayle observes, is, that each person remains more attached to his own opinion.

RESULTING Use, in *Law*. See Use.

RESUMMONS, Resummonitio, a second summons or calling a man to answer an action, where the first summons is defeated, or suspended, by an accident; as the death of a party, &c.

RESUMPTION, Resumptio, in a law-sense, signifies the taking again into the king's hands such lands or tenements as before, upon false suggestions, or other error, he had delivered to the heir, or granted, by letters patent, to any man.

Resumption, in the *Schools*, a summary repetition, or running over, of an argument, or of the substance of it, in order to refute it.

Resumption is also used by *Logicians* for the reduction of some figurative or quaint proposition, to a more intelligible and significant one.

RESUMPTIVE, in *Pharmacy*, an epithet given to a kind of unguent, used to recruit and restore arid languishing constitutions, and to dispose the dry bodies to receive nourishment. It is called in Latin *unguentum resumptivum*.

RESUPINATUM Folium, in *Botany*, a reversed leaf, has its proper under side turned uppermost, as in *Pharus latifolius*, and *Alstroemeria pelegrina*. See Leaf.

RESUPINATUS Flos, a reversed flower, is so circumstanced, that what, according to analogy, ought to be its upper side, is really the under. Of this *Lavandula*, Lavender, is an example, the longer lip of its corolla being uppermost, while the other, with the stamens and style, are downwards.

RESURRECTION, Resurrectio, *Resuscitation*, the act of returning to a new or second life, after having been dead.

The great argument for the truth of Christianity, and that urged with the most force and conviction for the same, is drawn from the resurrection of our Saviour. The circumstances of it are such as almost admit of a demonstration; which has accordingly been attempted on the strict principles of geometricians. See Ditton on the Resurrection.

The records of the fact of our Lord's resurrection are contained in the four gospels of St. Matthew, St. Mark, St. Luke, and St. John; and though the accounts given by these historians have been charged with some discrepancies and contradictions, the difficulties occasioned by them admit of a satisfactory solution. Among those who have made attempts for this purpose, Mr. Gilbert West (ubi infra) is entitled to our particular notice. With this view, he states the several incidents of this wonderful event, according to the order in which they seem to have arisen. He premises with observing, that our Saviour Christ was crucified on a Friday (the preparation, or the day before the Jewish Sabbath); gave up the ghost about three o'clock in the afternoon of the same day; and was buried that evening, before the commencement of the Sabbath, which, among the Jews, was always reckoned to begin from the first appearance of the stars on Friday evening, and to end at the appearance of them again on the day we call Saturday. He adds, that, some time, and most probably towards the close of the Sabbath, after the religious duties of the day had terminated, the chief priests obtained of Pilate, the Roman governor, a guard to watch the sepulchre, till the *third* day was past; pretending to apprehend that his disciples might come by night, and steal away the body, and then give out that he was risen, as he had predicted while he was yet alive. Accordingly a guard was set, the sepulchre made sure, and, to prevent the soldiers themselves from conniving with the disciples, a seal was put upon the stone which closed up the entrance of the sepulchre.

Some have objected to the evangelical statement of the time that elapsed between our Lord's death and resurrection; and they say, that the resurrection happened a day sooner than the prediction imported. But in the "Trial of the Witnesses," it is alleged, that the objection is founded upon a mistake of a mode of speaking, common to the Jews and other people; who, when they name any number of days and years, include the first and the last of the days or years to make up the sum. Christ, alluding to his own resurrection, says, "In three days I will raise it up." The angels report his prediction thus: "The Son of man shall be crucified, and the third day rise again." Elsewhere it is said, "after three days;" and again, that he was to be in the bowels of the earth "three days and three nights." These expressions are equivalent to each other; for we always reckon the night into the day, when we reckon by so many days. If you agree to do a thing ten days hence, you stipulate

ſtipulate for forbearance for the nights as well as days; and, therefore, in reckoning, two days, and two days and two nights, are the ſame thing. That the expreſſion, "after three days," means incluſive days, is proved by Grotius in Matth. xxvii. 63, and others. The prediction, therefore, was that he would riſe on the third day. Now, he was crucified, as we have already ſtated, on Friday, and buried; he lay in the grave the whole of Saturday, and roſe early on Sunday morning. But as the objectors ſay, he ought not to have riſen till Monday: let us try what the uſe of common language requires to be underſtood, in a like caſe. Suppoſe you were told that your friend ſickened on Friday, was let blood on Saturday, and the third day he died: what day would you think he died on? If you have any doubt about it, put the queſtion to the firſt plain man you meet, and he will reſolve it. The Jews could have no doubt in this caſe; for ſo they practiſed in one of the higheſt points of their law. Every male child was to be circumciſed on the eighth day. How did they reckon the days? The day of the birth was one, and the day of the circumciſion another; and though a child was born towards the very end of the firſt day, he was capable of circumciſion on any time of the eighth day. And, therefore, it is not new nor ſtrange, that the third day, in our caſe, ſhould be reckoned into the number, though Chriſt roſe at the very beginning of it. It is more ſtrange to reckon whole years in this manner; and yet this is the conſtant method obſerved in Ptolemy's canon, the moſt valuable piece of ancient chronology, next to the Bible, now extant. If a king lived over the firſt day of a year, and died the week after, the whole year is reckoned to his reign.

The order of the incidents our author conceives to have been as follows. Very early on the *firſt* day of the week (the day *immediately following* the ſabbath, and the *third* from the death of Chriſt), Mary Magdalene and the other Mary, in purſuance of the deſign of embalming the Lord's body, which they had concerted with the other women who attended him from Galilee to Jeruſalem, ſet out, in order to take a view of the ſepulchre, juſt as the day began to break; and about the time of their ſetting out "there was a great earthquake," &c. (Matth. xxviii. 2—4.) During the amazement and terror that occurred, Chriſt came out of the ſepulchre; and the keepers recovered from their trance and fled, when an angel, who till this time ſat upon the ſtone, quitted his ſtation on the *outſide*, and entered *into* the ſepulchre; and probably diſpoſed the linen clothes and napkin in that order in which they were afterwards found, and obſerved by John and Peter. Mary Magdalene, in the mean while, and the other Mary, were ſtill on their way to the ſepulchre, where, together with Salome (whom they had either called upon, or met as they were going), they arrived at the riſing of the ſun. And as they drew near, "they ſaid among themſelves, Who ſhall roll us away the ſtone from the door of the ſepulchre? for it was very great:" and they themſelves (the two Maries at leaſt) had ſeen it placed there two days before, and ſeen with what difficulty it was done. But whilſt they were deliberating (for it does not appear that they knew any thing of the guard), "lifting up their eyes," being yet at ſome diſtance, they perceived it *was* already *rolled* away. Alarmed at ſo extraordinary and ſo unexpected a circumſtance, Mary Magdalene, concluding that, as the ſtone could not have been moved without a great number of hands, it muſt have been rolled away with ſome deſign; and that this deſign could have been no other but to remove the Lord's body; and being convinced by appearances that this was the caſe, ran immediately to inform Peter and John of what ſhe had ſeen, and what ſhe ſuſpected; leaving Mary and Salome there, ſo that, if Joanna and the *other* women ſhould come in the mean time, they might acquaint them with their ſurpriſe at finding the ſtone removed, and the body gone, and of Mary Magdalene's running to inform the two above-mentioned apoſtles of it. While ſhe was going on this errand, Mary and Salome went on and entered into the ſepulchre; and there ſaw an angel "ſitting on the right ſide," &c. (Mark, xvi. 5—8.) After the departure of Mary and Salome came John and Peter, who, having been informed by Mary Magdalene, that the body of the Lord was taken away out of the ſepulchre, and that ſhe knew not where they had laid him, "ran both together to the ſepulchre," &c. (John, xx. 4—17.) After the appearance of Chriſt to Mary Magdalene, to whom, as St. Mark ſays expreſsly, he appeared firſt, the other Mary, and Salome, who had fled from the ſepulchre with ſuch terror and amazement, that "they ſaid not any thing to any man," (Mark, xvi. 8.), that is, as the expreſſion may be underſtood, had not told the meſſage of the angel to ſome (probably John and Peter, who were running with Mary Magdalene to the ſepulchre, about the time that theſe women were flying from it, and whom in their fright they might not immediately recollect), whom they met, and to whom they were directed to deliver it, were met on their way by Jeſus Chriſt himſelf, who ſaid to them, "All hail!" &c. (Matth. xxviii. 9, 10.) Theſe ſeveral women, and the two apoſtles, being now gone from the ſepulchre, "Joanna, with the other Galilean women, and others with them," &c. (Luke, xxiv. 1—9, 11.), Peter, who, upon the report of Mary Magdalene, had been *at* the ſepulchre, had *entered into* it, and, with a curioſity that beſpoke an expectation of ſomething extraordinary, and a deſire of being ſatisfied, had obſerved that the *linen clothes* in which Chriſt was buried, and the *napkin that was about his head*, were not only *left* in the ſepulchre, but carefully *wrapped up*, and laid in *ſeveral places*, and who, from theſe circumſtances, might begin to ſuſpect, what his companion St. John from the ſame circumſtances ſeems to have believed:—Peter we ſay, hearing from Joanna, that ſhe had ſeen a viſion of angels at the ſepulchre, who had aſſured her that Chriſt was riſen, ſtarting up, ran thither immediately; and knowing that the angels, if they were *within* the ſepulchre, might be diſcovered without his *going in*, he did *not*, as before, *enter in*, but *ſtooping down*, looked ſo far in as to *ſee* the *linen clothes*; and "departed, wondering in himſelf at that which was come to paſs." (Luke, xxiv. 12.) And either *with* Peter, or *about that time*, *went* ſome *other* diſciples, who were preſent when Joanna, and the other women, made their report; "and found it even ſo as the women had ſaid."—"The ſame day, two" of the diſciples "went to a village called Emmaus," &c. (Luke, xxiv. 13—35.) Such, according to Mr. Weſt, is the order in which the ſeveral incidents above related appear to have ariſen: and he concludes, that by this order, in which all the different events naturally and eaſily follow, and, as it were, riſe out of one another, the narration of the evangeliſts is cleared from all confuſion and inconſiſtencies; and, moreover, the proof of the reſurrection is better eſtabliſhed by thus *ſeparating* the women into two or more diviſions, than upon the contrary ſuppoſition, which brings them *all together* to the ſepulchre; for, in the laſt caſe, inſtead of *three different* appearances of angels to the women, and *two* of Jeſus Chriſt, we ſhould have but *one* of each; whereas, in the former, there is a train of witneſſes, a ſucceſſion of miraculous events, mutually ſtrengthening and illuſtrating each other, and equally and jointly concurring to prove one and the ſame fact:—a fact, which, as it was in its own nature more aſtoniſhing, and in its conſequences of the

the utmoſt importance to mankind, required the fulleſt and moſt unexceptionable evidence. Never, ſays our author, was a fact more fully proved; and in ſtating this proof, with a brevity correſponding to our limits, and yet, we truſt, with a clearneſs anſwerable to the importance of the ſubject, we ſhall avail ourſelves of the luminous arrangement which our author has made of the principal arguments that eſtabliſh the intereſting fact of our Lord's reſurrection, and that rendered it credible to the apoſtles and firſt diſciples; and by means of their teſtimony to perſons of countries and ages remote from thoſe in which it occurred. In its reference to the conviction of the apoſtles and firſt diſciples, the *firſt* object of conſideration comprehends the characters and diſpoſitions of the perſons who were themſelves to be convinced, and who were to be witneſſes of the reſurrection to the world in general; the *ſecond* includes the manner, *i. e.* the method and order in which the ſeveral proofs were laid before them; and the *third* is the matter of the evidence. The knowledge of the character and diſpoſition of the apoſtles and diſciples, for whoſe conviction the proofs of the reſurrection were primarily deſigned, is neceſſary to evince their aptitude and their ſufficiency for this purpoſe, and will ſerve to ſhew us, that the manner in which they were adduced, and the matter, or facts, of which they conſiſted, were ſelected with conſummate wiſdom. The apoſtles and firſt diſciples were, for the moſt part, perſons of low birth and mean occupations, unaccuſtomed to abſtract reaſoning and deep inquiry, and ſtrongly poſſeſſed with the national prejudices of the Jewiſh religion, as it was then taught by the Scribes and Phariſees. Although it appears from many paſſages in the goſpel hiſtory, that they were convinced by the numerous miracles which Jeſus of Nazareth performed, and by the accompliſhment of many prophecies in the hiſtory of his life, of his being the promiſed and expected Meſſiah; yet they were deluded by the notion prevalent among their brethren, the Jews, that the Meſſiah would be a temporal prince, a redeemer and ruler of Iſrael, who ſhould never die. Our Saviour, in many of his diſcourſes, laboured to undeceive them; but their prepoſſeſſions and errors were ſo deeply rooted, that all his efforts for this purpoſe proved ineffectual. He had, indeed, moſt circumſtantially foretold his own ſufferings, death, and reſurrection: but it ſufficiently appears, that they did not underſtand theſe predictions, until ſome time after their accompliſhment. As, in their opinion, immortality and temporal dominion were the characteriſtics of the Meſſiah, the ſufferings and death of Jeſus muſt have convinced them, before his reſurrection, that he was not the Meſſiah, or that perſon in whom they had truſted as the Redeemer and king of Iſrael. When he actually died according to his prediction, and his enemies ſeemed to have obtained a complete triumph over him, their minds muſt have been agitated by prejudice, doubt, perplexity, deſpair, and terror. The evidence, therefore, that was adapted to recover them from this ſtate, muſt, in the *manner* of its being preſented to them, as well as in its own nature, be of a peculiar kind: otherwiſe it could not have ſerved the purpoſe of converting them from being incredulous and ready to deſert their Maſter, into believers, teachers, and martyrs of the goſpel. The firſt alarm they received was from Mary Magdalene, who, early in the morning, on the third day from the burial of our Saviour, came running to inform Peter and John, that the ſtone was rolled from the mouth of the ſepulchre, and that the body of the Lord was removed. Theſe two apoſtles haſtened to the ſepulchre, and having entered it, found the fact that had been announced to them actually verified. Thus were their minds prepared for the extraordinary events that afterwards occurred. The life of Jeſus, they knew, had been a life of miracles; and his death had been attended with prodigies and wonders; and yet none of them, John excepted, believed that he was riſen from the dead; *for as yet* (as that apoſtle aſſures us) *they knew not the ſcriptures, that he muſt riſe again from the dead;* that is, they did not underſtand from the prophets, that the Meſſiah was to riſe again from the dead; being, on the contrary, perſuaded, that theſe very prophets had foretold the Meſſiah ſhould *not* die, but *abide for ever.* The next report they received was from Joanna, and her companions, who acquainted them that angels had appeared to them, and had told them that Jeſus was riſen, reminding them, at the ſame time, that Chriſt himſelf had, not only from the ſpirit of prophecy with which it was known that he was endowed, but from the prophets alſo, predicted his own ſufferings and death, and riſing again from the dead on the third day. But then they did not underſtand what was meant by his "riſing from the dead." In order to explain to them the meaning of the reſurrection, they were probably acquainted, in the next place, by Mary Magdalene, that ſhe had ſeen, not angels only, but Chriſt himſelf. Neverthelefs ſome doubts and difficulties ſtill remained. He had been ſeen only by Mary Magdalene. To relieve them in this ſtate of heſitation and perplexity, nothing could be better calculated than the account given by the other Mary and Salome, who had alſo been at the ſepulchre, and had there ſeen an angel, who not only aſſured them that "Chriſt was riſen," but had ordered them to tell his diſciples, "that they ſhould meet him in Galilee," agreeably to what he himſelf had ſaid to them in his lifetime. The only ſcruple that now remained in the minds of the apoſtles, aroſe from their not having ſeen him themſelves; and till they did, they ſeemed reſolved to ſuſpend their belief of his being riſen from the dead, and treated all thoſe viſions of the women as ſo many idle tales. They were left for ſome time to ruminate over the wonderful events that had rapidly occurred, to examine the ſcriptures, and to recollect the predictions and diſcourſes of their Maſter, to which they were referred both by the angels and himſelf. In order to aſſiſt them in their inquiries, and lead them to the true ſenſe of the ſcriptures, the only rational means of conquering their prejudice, Chriſt himſelf appeared to two of his diſciples, on their way to Emmaus, whom he found diſcourſing and reaſoning as they went upon thoſe very topics. The deſign of Chriſt in his converſation with theſe diſciples, and particularly in his expoſition of the prophets, was to ſhew, that, by the proper exerciſe of their underſtandings, they might, from thoſe very ſcriptures, whoſe authority they allowed, have been convinced that the Meſſiah "ought to have ſuffered," as they had ſeen him ſuffer, "and to riſe from the dead on the third day." That is, Chriſt choſe rather to convince them by *reaſon*, than by *ſenſe;* or, at leaſt, to prepare their minds, that their aſſent afterwards to the teſtimony of their ſenſes, ſhould be with the concurrence of their reaſon. Having duly prepared them for receiving the teſtimony of their ſenſes, he diſcovered himſelf to them by an act of devotion, "in breaking of bread;" a form of devotion which he had inſtituted in remembrance of his death. Accordingly they were convinced, and "returned that ſame hour to Jeruſalem," where they found the apoſtles aſſembled together, and debating apparently upon the ſeveral reports they had heard that day, and particularly upon what Peter had told them, to whom, ſome time on that day, Chriſt had appeared. The apoſtles having now had every kind of evidence laid before them that was requiſite to convince them of the reality of the reſurrection of Chriſt, and being alſo enabled by the gift of that Spirit, which inſpired the prophets, to underſtand the true meaning of thoſe ſacred oracles

to

to which their Master constantly referred them for the marks and characters of the Messiah, which *he* affirmed to be found in himself; they were left again to themselves, that they might consider and examine at leisure the several proofs of the resurrection, which they had heard and seen, and particularly those arising from the accomplishment of the predictions contained in the holy scriptures. Accordingly he forebore visiting them for eight days, after which he condescended to submit himself to a farther examination, in order to remove the unreasonable scruples of St. Thomas, one of the apostles. After this there seems to have been no scruple left in the minds of any of the apostles, to whom, however, Christ was still pleased to continue his visits; "being seen of them," as St. Luke testifies (Acts, i. 3.) "forty days after his passion, and speaking of the things pertaining to the kingdom of God."

It is observable, that all the appearances of Christ already mentioned, seem to have been intended only for the *conviction* of his apostles; and those that follow, which were probably much more numerous than the evangelical history records, rather for their *confirmation* and *instruction* in the faith and doctrines of the gospel. The sacred writers have been very particular in their accounts of the former, whilst they have mentioned but very few of the latter; and the reason of their different proceeding is very obvious. The apostles are to be considered both as *witnesses* of the miracles, and the sufferings, the death, and the resurrection of Jesus Christ, and as *teachers* and *preachers* of his doctrine. In the character of *witnesses*, a circumstantial account of the means and opportunities they had of knowing certainly the several facts attested by them, must necessarily give great force and credit to their evidence: whereas in that of *preachers*, it is sufficient if their auditors were satisfied, in general, that the doctrines taught by them were derived from the instructions, and authorised by the commission given them by their Master, "to teach all nations;" and of this, the various gifts of the Holy Spirit, poured out, not upon the apostles *only*, but *by* them upon *all* believers, were full and unquestionable proofs.

From a review of the method and order in which the several proofs of the resurrection were laid before the apostles, it is manifest that Christ required of them a reasonable and well-grounded faith, and that he also pursued the most proper and effectual means for the attainment of that end. With this view, instead of bearing down their reason, and dazzling their understanding by a full manifestation of himself at once, we see him letting in the light upon them by little and little, and preparing their minds by the gradual dawning of truth, that they might be able to bear the full lustre of the Sun of righteousness rising from the grave; to consider and examine, and know that it was he himself, and to assure the world it was impossible they could be deceived. By referring them to the scriptures, and submitting himself to the scrutiny and judgment of their senses, he not only waved all authority, but required them in a strong and particular manner to exercise their reason in examining the evidence brought before them; for which purpose he also improved their faculties by the infusion of his holy spirit. Never, says Mr. West, was evidence more fairly offered to consideration: never was inquiry put into a more rational method, as indeed there never were any facts that could better abide the test.

These facts, of which the *matter* of the evidence of the resurrection consisted, may be comprised under three heads, viz. the appearances of the angels, the appearances of Christ to the women, and the appearances of Christ to the disciples and apostles. Our limits will only allow us briefly to recite them. Those of the *first* class, at the sepulchre on the morning of the resurrection, are such as were observed by the Roman soldiers, who kept the sepulchre, by the other Mary and Salome, by Mary Magdalene and by Joanna, and her companions. Mr. West has satisfactorily proved, by a train of reasoning which we have not room to pursue, that these appearances of the angels were neither the effects of illusion, the phantoms of a distempered visionary mind, nor the operations of artifice and imposture. The *second* class comprehends the appearances of Christ, which were two; the first to Mary Magdalene; the second, to the other Mary and Salome. Some persons have very absurdly inferred from our Lord's prohibition to Mary, expressed in these words, "Touch me not, for I am not yet ascended to my Father," that our Saviour was not clothed with a real or material body: whereas the evident meaning of the words is "detain me not, for I am not yet ascending to my Father," and therefore they imply, that she should have another opportunity, before his departure from the world, of expressing her regard and maintaining intercourse with him. The *third* class of appearances includes those of Christ to his disciples, for the 40 days after his passion, which undoubtedly were numerous, though only few are recorded. An objection has been founded on one of these appearances, in recording which St. John says, "that Jesus came (the doors being shut) and stood in the midst," against the reality of the body of Christ; but it is needless to reply to so groundless a suggestion, as that the body of Christ passed through the solid door; when it is possible that he might enter, unperceived by them, through an open door.

The third time of our Saviour's appearance to any number of his disciples together after his resurrection was at the sea of Tiberias, called also the sea of Galilee (John, xxi. 14.); and subsequent to this was his appearance on a mountain in Galilee, mentioned by St. Matthew. One reason that has been assigned for his shewing himself in Galilee, after his resurrection, seems to have been, that, where he was personally known to so many people, having resided there above 30 years, he might have the greater number of competent witnesses to his resurrection. It is probable that the greatest number of his appearances for the 40 days after his passion were in Galilee, where he would have a favourable opportunity of discoursing to his disciples of "things pertaining to the kingdom of God," (Acts, i. 3.); and of preparing his apostles especially for testifying to the reality of his resurrection, and for executing the commission with which they were entrusted. Here they would be more secure, as well as more retired, than at Jerusalem.

It might be further urged that the resurrection of Christ was a necessary fulfilment of ancient prophecies pertaining to the Messiah, and also of our Lord's predictions: and that it was a no less necessary appendage to his office as a teacher and saviour than his death. Without the resurrection, the great scheme of divine mercy for the benefit of mankind would have been incomplete; by that, it was perfected, and the triumph over death added to that over sin; the Messiah thus accomplishing all that the scriptures foretold of his glory and power. This event authenticates and confirms the promise of future existence, and is indeed the pledge and earnest of immortality.

But it has been objected, that all the proofs of our Lord's resurrection which have been above adduced were not exhibited to all the Jews. (Acts, x. 41.) That Christ made choice of a select number of disciples, and particularly of twelve, (who were called apostles,) to be witnesses of the great actions of his life, and especially of his resurrection, and preachers of his gospel to all the world, is a well-known and indisputable

able fact. He not only, on many occasions, both *before* and *after* his crucifixion, discoursed to them in particular of things "pertaining to the kingdom of God," and poured upon them all the various gifts of the Holy Spirit, but gave them every kind of evidence of his "being risen" from the dead, which the most scrupulous and sceptical could imagine or require; "shewing himself alive to them by many infallible proofs," such as eating and drinking with them, "for 40 days after his passion." And, indeed, it is highly expedient that those, upon whose testimony and credit the truth of any fact is to be established, should have the fullest and most unexceptionable evidence of it, that can be had; because their having had all possible means of information must necessarily add great weight and authority to their depositions. That their perfect knowledge of the things which they were to testify was necessary for those who were ordained to be apostles, is further evident from the words of St. Peter, Acts, i. 15—26. It was the peculiar and distinguishing character of the apostles to be witnesses of the resurrection, and it was their office to testify to the reality of this fact: but all the infallible proofs of our Lord's resurrection were not vouchsafed by him to his disciples, merely from a particular favour and regard to *them*, that *they* might believe and be saved; but with a further view, that *others* also, by their testimony, founded on the most complete and exact information, might likewise believe and be saved. If Christ had intended nothing more than to induce his disciples to *believe* his resurrection, he might have left them to the *testimony* of the Roman soldiers; to that of the *women;* to the *writings* of *Moses* and the *prophets;* to his own *predictions;* to the *state* of the sepulchre, and that wonderful circumstance of his body's being *no where* to be found; and they would have been without excuse, if they had still continued unbelieving. But though the apostles had, upon *this* evidence, believed their master to be risen from the dead; yet, without those other *infallible* proofs mentioned by St. Luke, they would certainly have not been so *well* qualified for being witnesses of the resurrection to all the world: the heathens would not have admitted the *testimony* of Moses and the prophets, of whose writings they knew nothing, and of whose divine authority they had no proof. And as to the depositions of the *women;* besides their being strangers to *their* characters, they might, from Christ's appearing to *them*, with some colour have demanded, why he did not appear likewise to those whom he commissioned to *preach* his gospel, and to be *witnesses* of his resurrection. But when, on the contrary, the apostles could tell them, that they *themselves* had *seen* Christ, had *handled* him, *eat* and *drank* with him, and *conversed* with him for *forty* days *after* that he *was risen* from the dead, they could not but allow them to have had the *fullest* evidence of the resurrection, supposing what they told them to be *true;* and of this the purity of their doctrines, the holiness of their lives, their courage and constancy in defying and undergoing all kinds of hardships, dangers, pain, and death, in advancing a cause, which every worldly interest obliged them to desert, joined to the attestation of the Holy Spirit, "working with them, and confirming the word with signs following," were such assurances as no other man could give of his veracity. It has been said, however, that our Lord did not shew himself, after he was risen, to the Jews, to the chief priests and elders, to the Scribes and Pharisees, and mistakenly interpreting a passage in Matt. xii. 39, 40, Christ has been charged with a violation of his promise to this purpose. Of his rising again from the grave on the third day, the Jews had the testimony of the prophets, of the predictions of Christ himself, the evidence of the Roman soldiers, of his body's being no where to be found, of the women and disciples, and apostles, to whom he had appeared; and who, before the Sanhedrim, bore witness to his resurrection, and having just before wrought a miracle upon a lame man (Acts, iv. 10.) declared, that they had done it in the name of "Jesus of Nazareth, whom," say they, "ye crucified, whom God raised from the dead." This surely was evidence sufficient to convince any reasonable and unprejudiced person, and, consequently, to acquit our Lord of his promise of giving that "evil generation" satisfactory proofs of his being risen from the dead. To the evidence vouchsafed by Christ, neither out of favour to those "who had forsaken all and followed him;" nor to those whom he had chosen to be "witnesses of him to all the world," they certainly could have no just pretensions; who, instead of being his disciples, had rejected his doctrine, and put him to death as an impostor and blasphemer; and instead of shewing any disposition to embrace and propagate his gospel, opposed it with all their power, and, by threats and punishments, forbade his apostles to preach any more in his name. It deserves consideration in this place, that the apostles were not chosen merely to be witnesses of the fact of our Lord's resurrection, but they were appointed to their office, and commissioned to publish it to the world, because, having often seen Christ after his resurrection, they were duly qualified for the service assigned them, and were able to testify the truth of it from their own knowledge. Although our Saviour did not think proper to appear to the people at large; that is, to the multitude of the Jews, who were the declared enemies of his person and religion, and particularly to the chief priests and magistrates, who had been the instruments of his crucifixion; he *shewed himself openly*, without reserve and disguise, to those who had been accustomed to associate with him; and to no fewer than to five hundred such persons at one time; and of the number of these were the twelve apostles, who were specially appointed to preach his doctrine, and to declare the fact of his resurrection, as a distinguishing evidence of its truth and importance. Their office commenced during the period of his public ministry; and one necessary qualification for the future exercise of it was their being able to attest his resurrection. Others might have borne a similar testimony. They were prepared and disposed to do it. But the apostles were particularly selected and ordained for this purpose.

It is a very natural inquiry, why the Jews in general, and the priests and rulers in particular, should not have had an opportunity of seeing Christ after his resurrection, and conversing with him, and ascertaining the reality of the fact? As this was the evidence of his divine mission and character, to which he had often appealed; should not those who persisted in their incredulity, notwithstanding the proofs of supernatural powers, which he had exhibited in the course of his life and ministry, have enjoyed the benefit of it? And if it had been sufficient to overcome their obstinate prejudices, would not their testimony have contributed, more effectually than any other concurring circumstance, to the conviction of mankind in general, and to the credit and influence of Christianity? This kind of reasoning, we allow, seems, on a slight and superficial consideration of it, to be very plausible; and it has been strongly urged and very pertinaciously maintained by sceptics and infidels.

Let us examine the principles upon which it is founded; and we shall perceive that it is more plausible than just, and that it will not warrant the conclusion that has been drawn from it. It supposes, that the Jewish priests and magistrates had a right to expect personal evidence of our Saviour's resurrection; that some useful and important end would have been anſwered by its being afforded them; and that no injury to the character and religion of Chriſt could have reſulted from their being thus indulged and gratified. If neither of theſe ſuppoſitions can be reaſonably admitted; if, upon farther inveſtigation, they ſhould appear to be fallacious and unfounded; it cannot be alleged againſt the evidence of our Saviour's reſurrection, that it was defective and partial, becauſe it was not communicated to the Jewiſh prieſts and rulers.

The plea of right cannot be urged in their favour by any, who duly conſider, what their diſpoſition and conduct had been during our Saviour's life and miniſtry. Men who had diſcovered no inclination to examine the nature of his doctrine and the deſign of his miſſion; who had ſlighted and reſiſted the means of information and conviction, which his preaching and miracles had afforded them; and who had purſued him with malignity and violence to the croſs and grave;—ſuch men could ſurely have no juſt claims on his farther attention: they could have no reaſon to expect, that he would condeſcend to uſe any new efforts for removing their prejudices, when every paſt endeavour had not only proved fruitleſs, but had ſerved to exaſperate their reſentment, and to provoke a perſecution which terminated in his death. Their oppoſition to him had been ſuch both in its nature and degree, as to render them altogether unworthy of any forbearance and indulgence. Much leſs diſcernment than he poſſeſſed would have been ſufficient for perceiving, that no evidence was likely to avail with perſons of their temper and character. They had juſtly forfeited every token of his regard. They had merited the moſt ſignal puniſhment. It would have been not only a vain, but an impious and daring preſumption in them to expect any other evidence of his reſtoration to life beſides that, which they might derive from the teſtimony of perſons leſs guilty and more deſerving than themſelves. Beſides, our Saviour's particular commiſſion to the Jews expired with his death; and he had previouſly informed them that they ſhould not ſee him till they were better diſpoſed to receive him. Every perſonal claim muſt, in this caſe, be ſet aſide.

The plea of right being diſmiſſed as unfounded, the next queſtion that occurs is, whether any important and valuable purpoſe to themſelves or others, would have been anſwered by our Saviour's appearance to them, after his reſurrection? Have we any reaſon to imagine, that they would have been convinced of the truth of his miſſion and doctrine by ſuch an appearance? The ſame prejudices and intereſts that prevented the effect of the miracles which he had performed, and of which they had been witneſſes, would have reſiſted the conviction, which his reſurrection tended to produce. The ſame antipathy to the doctrine he taught and the religion he meant to eſtabliſh, would have prevailed againſt the evidence of this fact; and it is probable, that they would have only aggravated their guilt and condemnation by obſtinately perſiſting in their unbelief.

But though they were convinced of the reality of our Saviour's reſurrection, would they avow their conviction? Would they publicly teſtify the truth of that fact? By an undiſguiſed and open declaration of it, would they lead others to believe and acknowledge it? This, indeed, would have been a very ſignal triumph of truth over prejudice and malice. But it would have been a triumph over their own prejudice and malice, of ſo extraordinary a kind, that it was very unlikely to happen. Pride and intereſt would have been very reluctant in acknowledging that they had perſecuted and murdered a divine Meſſenger; in renouncing the worldly rank and influence which they poſſeſſed; and in ſubmitting to be taught and governed by the authority of Jeſus of Nazareth, whom they had deſpiſed, calumniated, and crucified. If they were conſtrained to aſſent to the truth of our Saviour's reſurrection, it was not very probable that they would confeſs to the world, that he, whom they had perſecuted during his life, and doomed to a premature and ignominious death, was the promiſed Meſſiah and Saviour. It was not very probable, that in ſo doing they would publiſh their own diſgrace, and that they would proclaim to the world, that they were perſecutors and murderers. It would have required a degree of virtuous fortitude, of which we diſcover no traces in the Jewiſh Sanhedrim, to bear public teſtimony to the reſurrection of a perſon whom they had ſo lately condemned and crucified as a malefactor. Without ſuch a teſtimony, of what avail would have been the conviction of their own minds to the general credit of the Chriſtian cauſe? Afraid or aſhamed of avowing it, and thus of forfeiting the reputation and influence annexed to their character and office, and of incurring popular cenſure and reproach; no benefit could have accrued from it either to their contemporaries or to future generations. They were, therefore, very unfit to be witneſſes of a fact, which it was their intereſt to conceal, and which they were not likely to acknowledge, if they had believed it to be true.

Beſides, their teſtimony, if truth had extorted it from them, and if they had poſſeſſed honeſty and reſolution ſufficient to avow it, would have been liable to ſuſpicion. It was the teſtimony of men whoſe minds muſt have been oppreſſed and terrified by a conſciouſneſs of their guilt; and it might have been ſaid, that they were haunted by ghoſts and ſpectres, and that their imagination converted a phantom into the real perſon of him whom they had expoſed to public deriſion, and ſentenced to an ignominious death. Their teſtimony would have gained little credit with men of their own rank and ſtation, and of principles and characters ſimilar to their own. It would have died with themſelves; and produced no effect beyond the circle of their own acquaintance and the age in which they lived.

It ought to be conſidered farther, that the character and religion of Chriſt might have been very materially injured by his appearance to the Jewiſh prieſts and rulers, after his reſurrection. They had no right to expect this kind of evidence. No good purpoſe could be anſwered by it. We now obſerve, that it might have been very detrimental in its effects. If they had remained unconvinced, which might moſt probably have been the caſe, the fact would have been queſtioned. The multitude would have become obſtinate and irreclaimable in their incredulity; and they would have pleaded the authority of their ſuperiors in ſtation and office, as an apology for neglecting inquiry and rejecting the means of conviction. If they had been convinced, without honeſty and reſolution to declare the truth, the fact would ſtill have been conſidered as doubtful, or at leaſt of no great importance. But if with their conviction they connected the public avowal of its truth, our Saviour would have incurred the charge of an impoſtor, and his religion of fraud. Loud would have been the clamour of a combination between him and the rulers of the ſtate. Suſpicion would have attached itſelf to the evidence of men, who had the care of his ſepulchre, who appointed the guard, and ſealed the ſtone that ſecured it, and who could eaſily have propagated a report, which would have gained credit with the ſervile multitude. Chriſtianity would have been repreſented, by perſons who are prone to aſcribe all religion to ſtate policy, as a contrivance of the prieſts and magiſ-rates of Judea, to anſwer ſome purpoſe of worldly emolument or ambition. Its progreſs and prevalence would have been attributed to the ſecular influence of its advocates; and it would have been deprived of that moſt diſtinguiſhing and ſatisfactory evidence which it now poſſeſſes, that it derived its origin from God, and owed its ſucceſs to the ſignal interpoſition of divine power.

Allowing that the apoſtles and firſt diſciples had ſufficient evidence of our Lord's reſurrection, we are next to inquire, in the diſcuſſion of this intereſting ſubject, how the fact may be aſcertained to the ſatisfaction of thoſe who live in ages and nations far remote from thoſe in which it occurred. Such perſons muſt recur for conviction, firſt and principally to the *teſtimony* of the original witneſſes, choſen to announce the fact to the world, tranſmitted from one country and one age to another in writings, either penned by themſelves, or authorized by their inſpection and approbation. Theſe writings are contained in the *Goſpels*, the *Acts*, the *Epiſtles*, and the *Revelation;* and for proofs of their authenticity and credibility, we refer to theſe titles, and alſo to BIBLE, CANON, and TESTAMENT; and for an account of their authors, to MATTHEW, MARK, LUKE, JOHN, PAUL, PETER, &c. How far we may ſafely, and without danger of miſtake, rely on the teſtimony of the witneſſes of our Saviour's reſurrection, thus tranſmitted to us, will appear, if we conſider, that they were men, not only capable of knowing the truth, and duly informed concerning it, but, on account of their general character, unlikely to report and propagate a falſehood. They had been raiſed from private and obſcure ſtations to the office they ſuſtained. They were deſtitute of thoſe natural talents and external advantages which ſuggeſt and favour a plan of impoſture and deceit. Artleſs and undeſigning, and unconnected with perſons of extended views and worldly influence, they were unfit inſtruments for concerting and executing a deliberate and complicated ſcheme of deluſion. The principles they had embraced, and the profeſſion they had aſſumed, ſince their converſion to Chriſtianity, were altogether incompatible with a combination to promote the prevalence of a known falſehood. Integrity and a regard to truth, under the awe of the God of truth and juſtice, and in the proſpect of righteous judgment and retribution, were the avowed principles of their conduct; and they muſt have been impoſtors, chargeable with the moſt atrocious guilt and the moſt conſummate folly, if they had propoſed, by the wickedneſs of deceit, to promote the cauſe of truth and virtue. But the falſehood of aſſerting, that Chriſt was riſen, was ſuch as would never have engaged their concurrence and ſupport. It was an event of which they had no expectation. Their prejudices and falſe hopes had led them to ſurrender their cauſe, as altogether defeated, when their Maſter ſubmitted to death. They had either forgotten or miſunderſtood his predictions; and when ſome of them firſt received the report of his reſurrection, they were departing from Jeruſalem with dejected and deſpairing ſpirits; and they needed very peculiar evidence of the fact, before they were diſpoſed to admit the reality of it. If Chriſt had not actually riſen from the dead, theſe men would have returned to their former attachments and occupations. All their prepoſſeſſions in favour of the perpetuity of the law of Moſes would have revived. Diſappointed in their erroneous expectations, they would have been the leſs inclined to propagate an impoſture.

More eſpecially when we conſider, that all their intereſts, as well as their prejudices, militated againſt their public declaration of a fact, which had never exiſted. Can we ſuppoſe, that they would have incurred the reſentment of the whole body of the Jews; and that they would have hazarded their lives in the ſupport of a cauſe, the founder of which had deceived and betrayed them? On the contrary, we diſcern in the temper and conduct of the witneſſes of our Lord's reſurrection undeniable evidence of their conviction of its truth, and of their ſincerity in avowing and publiſhing it. Nothing leſs than the evidence of truth can account for the change which they manifeſted both in their ſentiments and conduct. Men, who a little while before were timid and deſpairing, become bold and fearleſs; declare the fact on the ſcene, where they report it to have happened, and in the preſence of thoſe, who, after having ſucceeded in procuring the crucifixion of Chriſt, employed all the means in their power for preventing any deluſion with regard to his reſurrection; and who expoſe themſelves to perſecution and death in aſſerting and proclaiming it. With new views, with reſpect to the nature and extent of the Chriſtian diſpenſation; with a knowledge and zeal, with a ſteadineſs and conſtancy, which indicate a conſciouſneſs of truth and an extraordinary illumination; they publiſh the fact, and propagate the doctrines and duties which it was deſigned to eſtabliſh and enforce.

Beſides, "the apoſtles wrought miracles in confirmation of the truth of their teſtimony." The God of truth concurred with them, and atteſted their credibility; and thus obviated every doubt and difficulty, which prejudice and malignity might have ſuggeſted. Every miracle they performed was a new atteſtation to the fact which they reported, and the extraordinary powers they poſſeſſed, and which they derived from the Sovereign of nature, qualified them for being proper witneſſes of it to the world. He, who appointed them to this office, aided them in the execution of it. Their ſucceſs, inſufficient as they were of themſelves to combat the prejudices and powers of the world, afforded an increaſing and permanent evidence of the fact, on which their commiſſion was founded. To us their teſtimony has deſcended with every ſanction and with every circumſtance of credibility, that can juſtify our aſſent, and our attachment to the doctrine they taught, and to the practice of the duties they inculcated.

In the prevalence and duration of Chriſtianity, and in the proſpect of its continued ſubſiſtence and increaſing ſpread and triumph, we diſcern traces of its divine original: we ſee exiſting proof of the reſurrection of its founder; and we perceive reaſons and motives for holding faſt the profeſſion of our faith in it without wavering. Our religion is founded on evidence, that cannot be reaſonably queſtioned: the objections to which it is liable, furniſh, on due examination, arguments in its favour. It needs only an impartial ſcrutiny and trial, in order to approve itſelf *the wiſdom and the power of God.*

From the exiſtence of the Chriſtian religion, which we may conſider as a diſtinct argument in proof of our Saviour's reſurrection, may be deduced the ſame kind of evidence of this fact, as is exhibited to us of the deluge by the many petrifactions of ſhells and bones of fiſhes, and other animals of diſtant regions, &c. found often in the bottoms of the deepeſt mines, and the bowels of the higheſt mountains; for, as it is impoſſible to account for thoſe various petrifactions being lodged in ſo many parts of the earth, ſome many leagues diſtant from the ſea, others very much above the level of it, without admitting ſuch a ſubverſion and confuſion of this globe, as could not have been occaſioned by a leſs violent cauſe than the "breaking up of the fountains of the great deep, and the waters flowing above the tops of the higheſt hills;" ſo will it be extremely difficult to account for the propagation and preſent exiſtence of Chriſtianity in ſo many regions

regions of the world, without ſuppoſing that "Chriſt roſe from the dead," aſcended into heaven, and enabled his diſciples, by the miraculous gifts of his holy ſpirit, to ſurmount ſuch obſtacles, as no mere human abilities could poſſibly overcome. See CHRISTIAN *Religion.* "Obſervations on the Hiſtory and Evidences of the Reſurrection of Jeſus Chriſt," by Gilbert Weſt, eſq. "Obſervations on the Converſion of St. Paul," by the right hon. George lord Lyttelton. "The Trial of the Witneſſes of the Reſurrection of Jeſus." Rees's Sermons, vol. i. Serm. 4.

The reſurrection of Chriſt is a moſt important fact, not only as it certifies his divine miſſion, the character he aſſumed, and the truth of the doctrine he taught, but as it aſſures us of the reality of a future ſtate of righteous retribution. This event exhibits a triumph over death, which proves not merely the poſſibility, but the certainty, of a general reſurrection of mankind. It is the pledge and earneſt of that reſtoration to life, which Jeſus Chriſt, as a divine teacher, both predicted and promiſed. Many curious queſtions have been propoſed on the mode of the future exiſtence of mankind; as well as on the place of abode of the good and wicked (ſee HEAVEN and HELL); and alſo on the time when this intereſting event ſhall happen. (See SLEEP *of the Soul.*) With regard to the mode of our future being, it is generally allowed, both by thoſe who believe and thoſe who deny the eſſential diſtinction between matter and ſpirit, that we ſhall exiſt hereafter in a corporeal form; but the difference between our preſent bodies and thoſe in which we ſhall exiſt after the general reſurrection is a ſubject, which, however it may have engaged the attention and employed the pens of metaphyſicians and polemical theologians, is more curious than uſeful; and provided that we ſhall exiſt hereafter, we need not be anxious about the deciſion of this queſtion. It is important merely as it relates to the doctrine of a future exiſtence in general, the truth of which, whatever may be the conjectures of the learned, it does not invalidate.

Many Chriſtians believe the reſurrection of the ſame identical body, the very ſame fleſh and bones, at the day of judgment. The two principal philoſophical objections againſt it are theſe:

1. That the ſame piece of matter, or ſubſtance, may happen to be a part of two or more bodies. Thus a fiſh feeding on a man, and another man afterwards feeding on the fiſh, part of the body of the firſt man becomes firſt incorporated with the fiſh, and afterwards in the fiſh, with the laſt man. Again, inſtances have been known of one man's feeding immediately on another; and, among the cannibals of the Weſt Indies, the practice has been frequent.

Now, where the ſubſtance of one is thus converted into the ſubſtance of another, each cannot riſe with his whole body; and to which ſhall the common part be allotted?

To this objection ſome anſwer, that, as all matter is not fit or diſpoſed to be aſſimilated to the body, and incorporated with it, human fleſh may very probably be of this kind; and, therefore, what is thus eaten, may be again excreted, and carried off. But Mr. Leibnitz's anſwer ſeems the more ſolid. All that is eſſential to the body, he urges, is the original ſtamen which exiſted in the ſemen of the father; nay, and on the footing of the modern theory of generation, which exiſted in the ſemen of the firſt man. This we may conceive as the moſt minute ſpeck or point imaginable; and therefore, not to be ſeparated, or torn aſunder, and any part of it united with the ſtamen of any other man. All this bulk we ſee in the body, is only an accretion to this original ſtamen; an addition of foreign matter, of new juices, to the primary, ſolid ſtamen: there is, therefore, no reciprocation of the proper matter of the human body.

The ſecond objection is this: the human body, we know, by the late diſcoveries in the animal economy, is continually changing; a man has not entirely the ſame body to-day as he had yeſterday; and it is even computed, that in leſs than ſeven years' time, his whole body undergoes a change, and not a particle of the ſame body remains. Which of thoſe many bodies, then, which the ſame perſon has in the courſe of his life, is it that ſhall riſe? or does all the matter that has ever belonged to him riſe again? or does only ſome particular ſyſtem thereof? The body, *e. gr.* he had at twenty, at thirty, or at ſixty years old? If only this or that body ariſe, how ſhall it be rewarded or puniſhed for what was done in the other? with what juſtice does one perſon ſuffer, &c. for another?

To this it may be anſwered on Mr. Locke's principles, that perſonal identity, or the ſameneſs of a rational being, conſiſts in ſelf-conſciouſneſs; in the power of conſidering itſelf the ſame thing in different times and places. By this every one is to himſelf what he calls *ſelf;* without conſidering whether that ſelf be continued in the ſame or divers ſubſtances. So far reaches the identity of that perſon. It is the ſame ſelf now it was then; and it was by the ſame ſelf which now reflects on an action, that action was performed.

Now, it is this perſonal identity that is the object of rewards and puniſhments, which we have obſerved may exiſt in different ſucceſſions of matter; ſo that to render the rewards and puniſhments juſt and permanent, nothing needs but that we riſe again with ſuch a body as that we retain the conſciouſneſs of our paſt actions.

RESUSCITATION. See RESURRECTION, and REVIVIFICATION.

RESUSCITATION *of Plants*, in *Chemiſtry*, the art of reproducing a plant from its aſhes. See PALINGENESIA.

Many have pretended to this art, and have ſhewn reſuſcitated plants in vials; but all theſe ſeem only particular inſtances of artificial chemical vegetations, of which many others may be given. The external appearances of theſe reſemble plants, and the ignorant may eaſily take them for ſuch; but when cloſely conſidered, there is a great difference to be found. See *Artificial* VEGETATION.

RETAIL, in *Commerce*, &c. the buying of goods in the great, or by wholeſale, and ſelling them out again in ſmall parcels.—"Qui rem integram ementes, per minutiores eam partes diſtrahebant."

RETAIN, *To*, ſpoken of mares, ſignifies *to hold*, *i. e.* to conceive after covering.

RETAINER, in *Law*, a ſervant not menial or domeſtic, that is, not continually dwelling in the houſe of his lord and maſter, but only wearing his livery, and attending on ſpecial occaſions.

This livery was anciently given by a great man, and frequently for the maintenance of quarrels; whence it was juſtly prohibited by ſeveral ſtatutes; as under Richard II. on pain of impriſonment, and grievous forfeiture to the king.

It was further prohibited by other ſtatutes of the ſucceeding kings, by which the delinquents were ſubject to make ranſom at the king's pleaſure; and knights and eſquires hereof duly attainted were to loſe their ſaid liveries, and forfeit their fees for ever.

Edward IV. added a ſpecial penalty of five pounds *per* month on every man that gave ſuch livery, and as much on every perſon ſo retained, either by writing, word, or

oath.

oath. But moſt of theſe ſtatutes are repealed by a ſtatute 3 Car. I.

RETAINER *of Debts*, a remedy which the law gives to an executor or adminiſtrator for the debt, by allowing him to retain ſo much as will pay himſelf, before any other creditors whoſe debts are of equal degree. (See DEBT.) The debts of co-executors ſhall be diſcharged in proportion. An executor of his own wrong ſhall not, in any caſe, be permitted to retain.

RETAINING-FEE, is the firſt fee given in any cauſe to a ſerjeant or counſellor at law, by which to make him ſure, that he ſhall not be on the contrary ſide.

RETALIATION, RETALIATIO, the act of returning like for like. See TALIONIS *Lex*.

When a nation cannot obtain juſtice, either for a loſs or an injury, it has a right to do itſelf juſtice. But before it declares war, there are various methods practiſed among nations for obtaining ſatisfaction. Among theſe is that called the law of retaliation, according to which we make another ſuffer exactly ſo much evil as he has done. Many have extolled this law, as being derived from the moſt ſtrict juſtice; and can we be ſurpriſed at their having propoſed it to princes, when they have even dared to give it for a rule to the Deity himſelf! The ancients called it the law of Rhadamanthus. Although a nation may puniſh another which has done it an injury, if it refuſes to give juſt ſatisfaction; yet it has not a right to extend the penalty beyond what is required by its own ſafety. Retaliations, unjuſt between private perſons, would be much more ſo between nations, becauſe here the puniſhment would, with difficulty, fall on thoſe who have done the injury. What right would you have to cut off the noſe and ears of the ambaſſador of a barbarian, who had treated yours in the ſame manner? As to thoſe repriſals in time of war, which partake of the nature of retaliation, they are juſtified on other principles. (See REPRISALS.) All that is true in this idea of retaliation is, that every thing be equal; the pain ought to bear ſome proportion to the evil required to be puniſhed; the end and even the foundation of puniſhment requiring thus much.

RETARDATION, RETARDATIO, in *Phyſics*, the act of retarding; that is, of delaying the motion or progreſs of a body, or of diminiſhing its velocity.

The retardation of moving bodies ariſes from two great cauſes, the *reſiſtance of the medium*, and the *force of gravity*.

The RETARDATION *from the Reſiſtance* is frequently confounded with the reſiſtance itſelf; becauſe, with reſpect to the ſame moving body, they are in the ſame proportion. See RESISTANCE.

With reſpect to different bodies, however, the ſame reſiſtance often generates different retardations. For if bodies of equal bulk, but different denſities, be moved through the ſame fluid with equal velocity, the fluid will act equally on each; ſo that they will have equal reſiſtances, but different retardations; and the retardations will be to each other as the velocities which might be generated by the ſame forces in the bodies propoſed; that is, they are inverſely as the quantities of matter in the bodies, or inverſely as the denſities.

Suppoſe, then, bodies of equal denſity, but of unequal bulk, to move equally faſt through the ſame fluid, their reſiſtance increaſes according to their ſuperficies; that is, as the ſquares of their diameters. But the quantities of matter are increaſed in proportion to the cubes of the diameters: the reſiſtances are the quantities of motion; the retardations are the celerities ariſing from them; and dividing the quantities of motion by the quantities of matter, you will have the celerities; therefore the retardations are directly as the ſquares of the diameters, and inverſely as the cubes of the diameters; that is, inverſely as the diameters themſelves.

If the bodies be equal, move equally ſwift, and are of the ſame denſity, but move through different fluids, their retardatious are as the denſities of thoſe fluids.

And when bodies equally denſe, and of equal bulk, are carried through the ſame fluid with different velocities, the retardations are as the ſquares of the velocities.

The RETARDATION *from Gravity* is peculiar to bodies projected upwards. A body thrown upwards is retarded after the ſame manner as a falling body is accelerated; only, in the one caſe, the force of gravity conſpires with the motion acquired; and in the other, it acts contrary to it.

As the force of gravity is uniform, the retardation from that cauſe will be equal in equal times.

Hence, as it is the ſame force which generates motion in the falling, and diminiſhes it in the riſing body, a body riſes till it has loſt all its motion; which it does in the ſame time in which a body falling would have acquired a velocity equal to that with which the body was thrown up.

Thus, alſo, a body thrown up will riſe to the ſame height, from which falling, it would acquire the velocity with which it is thrown up; therefore the heights, which bodies thrown up with different velocities can riſe to, are to each other as the ſquares of the velocities.

Hence, the retardations of motions may be compared together: for they are, firſt, as the ſquares of the velocities; ſecondly, as the denſities of the fluids through which the bodies are moved; thirdly, inverſely, as the diameters of thoſe bodies; laſtly, inverſely, as the denſities of the bodies themſelves.

The numbers in the ratio compounded of thoſe ratios, expreſs the proportion of the retardations; multiplying the ſquare of the velocity by the denſity of the fluid, and dividing the product by the product of the diameter of the body multiplied into its denſity; and working thus for ſeveral motions, the quotients of the diviſions will have the ſame compound ratio to one another.

RETARDATION *of Motion, Laws of*. 1. If the motion of a body be uniformly retarded, that is, if its celerity be diminiſhed equally in equal times, the ſpace it paſſes over is one half of that it would paſs over in the ſame time by an uniform motion.

2. The ſpaces deſcribed in equal times by an uniformly retarded motion, decreaſe according to the uneven numbers 9, 7, 5, 3, &c. See ACCELERATION and MOTION.

RETCH, or RETCHES, a name given by our farmers to an iron, or a pair of irons, which in the common plough ſerve to faſten the ſheet to the beam. The retches are faſtened to the ſheet with nails, and to the beam with pins.

RETCHANI, in *Geography*, a town of Ruſſia, in the government of Pikov; 16 miles S. of Tropetz.

RETCHING, or REACHING, the effort or endeavour to vomit. See NAUSEA.

RETCHNA, in *Geography*, a circar or province of Hindooſtan, ſituated between the rivers Rauvee and Chunaub; in which are the cities of Lahore, Ameenadab, Sealcot, and ſeveral other towns.

RETE MALPIGHII, in *Anatomy*, the network compoſing the cellular ſtructure of the lungs.

RETE *Mirabile*, the plexus of veſſels formed by the internal carotid arteries of animals, before they branch out to the brain. See MAMMALIA.

RETE *Mucoſum*, the ſoft delicate layer of the integuments interpoſed between the cuticle and the true ſkin, in which

which the colour of the ſkin reſides. This part is much thicker in the dark coloured than in the light races of man, and is black in the Negro. See INTEGUMENTS.

RETE *Teſtis*, a part of the excretory apparatus of the teſticle. See the deſcription of that gland in the article GENERATION.

RETE *Peny*, in *Ancient Records*, a cuſtomary due of one penny for every perſon to the pariſh prieſt.

RETEH, or ARRATAMA, in *Geography*, a diſtrict of Africa, in the country of Sugulmeſſa.

RETEINER, or RETAINER. See RETAINER.

RETENEGI, in the *Materia Medica*, a name uſed by Avicenna, and others, to expreſs the common reſin of the pine, or fir-tree, and ſometimes common black pitch. The lexicographers have given us *ſtorax* as the explanation of retenegi, but this is not warranted by any paſſage in the authors who uſe the word. It is certain, indeed, that the generality of authors have confounded the ſeveral ſorts of reſin and pitch-making trees together, and among them the pine, fir, cedar, and turpentine trees, are called by the ſame name, but the ſtorax-tree is never included among the number. Theſe were only confounded together, becauſe of the ſimilitude of the things they produced; but the ſtorax was too different from all theſe, and too precious a gum not to be diſtinguiſhed.

RETENTA, a word uſed by the medical writers to expreſs things retained in the body, or which are not to be retained in a ſtate of good health.

RETENTIO, RETINENTIA, in our law-books, is ſometimes uſed to ſignify retinue.

RETENTION, RETENTIO, a faculty of the human mind, by which, in order to a farther progreſs in knowledge, it keeps or retains thoſe ſimple ideas, which it before received by ſenſation or reflection.

This is done two ways. Firſt, by keeping the idea which is brought into the mind for ſome time actually in view. This is called *contemplation*.

Secondly, by reviving thoſe ideas in our minds, which have diſappeared, and have been, as it were, laid out of ſight. This is *memory*, which is, as it were, the repoſitory of our ideas.

RETENTION is alſo uſed, in *Medicine*, &c. for the ſtate of contraction in the ſolids, or vaſcular parts of the body, which makes them hold faſt their proper contents.

In this ſenſe, retention ſtands oppoſed to evacuation and excretion.

Retention and excretion make two of the non-naturals.

RETENTION is alſo frequently conſidered as a diſorder, and defined the act of retaining the excrements, humours, &c. ſo as they cannot be voided out of the body. See INFANT.

It is the retention of peccant humours which cauſes ſuch a diſeaſe.

RETENTION *of Urine*. See URINE, *Retention of*.

RETFORD, EAST, in *Geography*, a market and borough-town in North Clay diviſion of the wapentake of Baſſetlaw, county of Nottingham, England, is ſituated on the eaſtern bank of the river Idle, at the diſtance of 29 miles N.N.E. from Nottingham, and 145 miles N. by W. from London. Retford conſiſts of two diſtinct parts, or diſtricts, reſpectively named, from their poſition to the river, Eaſt and Weſt Retford; the former of which is ſtrictly the market-town, and the latter a ſeparate pariſh, or ſuburb. Edward II. granted to the burgeſſes the right of chooſing bailiffs for the government of the town; and Henry III. granted them a fair. By a charter from Henry VI., the bailiff was empowered to hold a court of record, and to execute the office of eſcheator and clerk of the market. Theſe immunities have ſince been confirmed, and others added by James I.; under whoſe charter, Retford is now governed by two bailiffs, a ſteward, twelve aldermen, two chamberlains, a town-clerk, and two ſerjeants at mace. The bailiffs and ſteward for the time being are juſtices of the peace, and of the quorum, within the borough. Retford ſends two members to the national ſenate, and theſe are choſen by about 150 voters, compoſed of the bailiffs, aldermen, and freemen. Like moſt other ſmall boroughs, it has occaſionally been the ſcene of warm election conteſts. This place firſt exerciſed the right of repreſentation in the early part of the reign of Edward II.; but it ſeems to have allowed this privilege to remain dormant from the ninth year of that king till the thirteenth year of queen Elizabeth, when the ſame was reſumed, and has continued to be regularly exerciſed ever ſince. Formerly the county aſſizes were held here; but of late years all criminal trials have taken place at Nottingham, the county town.

Retford market-day is Saturday, weekly; and there are, beſides, two annual fairs for horſes and black cattle, held on the 23d of March and the 2d of October. At the commencement of the laſt century, a conſiderable malting buſineſs was carried on here; but Workſop has occaſioned its decline. At preſent, Retford is ſupported principally by its hat and ſail-cloth manufactories. Major Cartwright ſome years ago eſtabliſhed a worſted mill in the immediate vicinity; but the project, having proved unſucceſsful, has been abandoned. An agricultural ſociety was eſtabliſhed here in 1799, under the auſpices of the duke of Portland, viſcount Newark, colonel Eyre, and others.

The public buildings in Retford are the town-hall, Sloſwick hoſpital, a free-ſchool endowed by Edward VI., an alms-houſe for twelve poor women, and the pariſh church. The laſt, called the corporation church, is a ſmall, but neat, edifice, in the Engliſh ſtyle of architecture, though much modernized, particularly in the interior. The living is a vicarage, in the patronage of the duke of Devonſhire.

On the weſtern bank of the Idle, and connected with the borough by a handſome modern bridge, is the village of Weſt Retford, which, however, is altogether diſtinct from Eaſt Retford, both as to civil and eccleſiaſtical juriſdiction. Here is an hoſpital, which was founded in 1666 by John Dorrel, M.D., for ſixteen poor perſons, who are allowed annually 10*l*. each, beſides clothing, coals, &c. Much injury was done to this village by a heavy flood, which occurred in 1795; but it is neverthelеſs a very thriving place, as well as Eaſt Retford, and derives conſiderable advantage from its proximity to the Cheſterfield canal. Weſt Retford Hall, a ſeat of the Emerſon family, is the moſt conſpicuous ornamental object in the immediate neighbourhood. St. John's well, a mineral ſpring about a mile from Retford, has been long famed for its medicinal qualities. South-eaſt of Retford is Grove-Hall, the ſeat of Anthony Hardolph Eyre, eſq., M.P. for the county. The houſe is ſeated on an eminence in a finely wooded park. Thoroton's Hiſtory of Nottinghamſhire, folio, 1663. republiſhed with large additions by John Throſby, 3 vols. 4to. vol. iii. Beauties of England and Wales, vol. xii. by Mr. Laird.

RETHEL, a town of France, and principal place of a diſtrict, in the department of the Ardennes; before the revolution, the capital of a ſmall country, called the "Retelois." The place contains 4862, and the canton 12,473 inhabitants, on a territory comprehending 200 kiliometres, in 23 communes. N. lat. 49° 30'. E. long. 4° 27'.

RETHEM, a town of Weſtphalia, in the principality of of Luneburg Zell, on the Aller; 32 miles W. of Zelle. N. lat. 52° 51′. E. long. 9° 18′.

RETHONDES, a town of France, in the department of the Oise; 5 miles N.E. of Compeigne.

RETHWISCHE, a town of the duchy of Holstein; 25 miles N.E. of Hamburg.

RETI, in *Hindoo Mythology*, a personification of Affection, and the fabled consort of Kama, the god of love. She is represented in pictures as a beautiful woman, on horseback sometimes, and in the act of throwing a lance. Allusions to this goddess, proverbial for beauty, occur very frequently in Hindoo writings. Under the article RADHA, that lovely goddess describes the glances of her eye as "keener than the arrows darted by the husband of Reti." She sometimes is styled "mother of Kama." That appellation occurs in the article RUKEKA of this work. Kama is often called "he who lovest the goddess Reti." On the occasion of the combustion of the god of love, as noticed under KAMA, the lamentations of the afflicted Reti are very touchingly related by the celebrated Kalidasa, author of Sakuntala. A whole book of his poem, entitled "Kumara-sambhava, or the Birth of Kumera," is occupied with her tender sorrows. This book sir W. Jones's teacher, a learned Vaidya (see VAIDYA), was restrained from reading; considering the ceremonies of a marriage, that of Kama and Reti, at which Brahma himself officiated as father of the bridegroom, as too holy to be known by any but Brahmans. An instance somewhat similar, of a book being too holy to be read by individuals of an inferior class, is given under RAMAYANA. Farther particulars connected with the interesting goddess, the subject of this article, will be found under KAMA, KRISHNA, and PRADYAMNA.

RETIARII, in *Antiquity*, a kind of gladiators, thus denominated from a net which they made use of against their antagonists, who were called *secutores*, and sometimes *myrmillones*. See GLADIATOR.

The word is formed from the Latin, *rete, net;* or perhaps from *retejaculum;* for they call their net *jaculum*, and sometimes in one word *retejaculum*.

This net they carried under their buckler, and, when opportunity served, cast it over the head of their antagonist, and, in this condition, killed him with a trident, or three-grained spear, which they bore in the other hand.

Lipsius and others observe, that they fought in tunics, and were furnished with sponges to wipe off the sweat, blood, &c. and to stop their wounds.

RETICENCY, RETICENTIA, a figure in *Rhetoric*, by which we make oblique mention of a thing, in pretending to pass it over unmentioned.

Thus: *to say nothing of the nobility of his ancestors: I forbear to speak of his courage, and pass over the severity of his morals*. See APOSIOPESIS and PRETERITION.

RETICULA, RETICULE, in *Astronomy*, a contrivance for the exact measuring of the quantity of eclipses, introduced several years ago by the Royal Academy of Paris. See ECLIPSE.

The reticule is a little frame, consisting of thirteen fine silken threads, equidistant from each other, and parallel; placed in the focus of object-glasses of telescopes; that is, in the place where the image of the luminary is painted in its full extent. Of consequence, therefore, the diameter of the sun and moon is by this seen divided into twelve equal parts or digits; so that, to find the quantity of the eclipse, there is nothing to do but to number the luminous and the dark parts.

As a square reticule is only proper for the diameter, not for the circumference of the luminary, it is sometimes made circular, by drawing six concentric equidistant circles. This represents the phases of the eclipse perfectly.

But it is evident, that the reticule, whether square or circular, ought to be perfectly equal to the diameter or circumference of the sun or star, such as it appears in the focus of the glass, otherwise the division cannot be just. Now this is no easy matter to effect, because the apparent diameter of the sun and moon differ in each eclipse; nay, that of the moon differs from itself in the progress of the same eclipse.

Another imperfection in the reticule is, that its bigness is determined by that of the image in the focus; and of consequence it will only fit one certain magnitude.

But M. de la Hire has found a remedy for all these inconveniencies, and contrived that the same reticule shall serve for all telescopes, and all magnitudes of the luminary in the same eclipse. The principle on which his invention stands is, that two object-glasses applied against each other, having a common focus, and there forming an image of a certain magnitude, this image will increase in proportion as the distance between the two glasses is increased as far as a certain limit.

If, then, a reticule be taken of such a magnitude, as just to comprehend the greatest diameter the sun or moon can ever have in the common focus of two object-glasses applied to each other, there needs nothing but to remove them from each other, as the star comes to have a less diameter, to have the image still exactly comprehended in the same reticule.

Another improvement is, that whereas the silken threads are subject to swerve from the parallelism, &c. by the different temperature of the air; a reticule may be made of a thin looking-glass, by drawing lines or circles on it with the fine point of a diamond; which shall be safe from any alteration of the air. See MICROMETER.

RETICULAR BODY, *corpus reticulare*, in *Anatomy*, a body of vessels lying immediately under the cuticle or scarf-skin. See INTEGUMENTS.

RETICULAR *Plexus*, *plexus reticularis*, sometimes denotes the choroides, which is thus called, because its fibres are interwoven like a net.

RETICULARIA, in *Botany*, a genus of *Fungi*, named by Bulliard, from the reticulated appearance of its structure when ripe. It is the LYCOGALA of Micheli, Persoon, and others; see that article.

RETICULARIS MEMBRANA, in *Anatomy*, a name sometimes given to the cellular substance. Dr. Hunter speaks of the cellular substance, which contains no fat, under this name, giving the appellation of adipous cellular substance to the other.

RETICULUM, in *Comparative Anatomy*, one of the divisions of the stomach in ruminating animals, so called from the reticulated arrangement of the folds of its internal membrane. See MAMMALIA.

RETIERS, in *Geography*, a town of France, in the department of the Ille and Vilaine, and chief place of a canton, in the district of Vitré; six miles W.S.W. of La Guerche. The place contains 2384, and the canton 14,638 inhabitants, on a territory of 237½ kiliometres, in 10 communes.

RETIMO, a town of the island of Candia, built on the ruins of the ancient Rithymna. The environs of this town afford prospects that are very picturesque:—gardens planted with orange-trees, among which rise some date-trees; fields covered with olive-trees and kitchen-garden plants; rising grounds, on which the vine, the fig-tree, the mulberry-tree, and the almond-tree grow together; and farther

farther on, wooded mountains:—to the weft, the citadel, the harbour, and the fea. In a word, every thing concurs to render Retimo the moft agreeable town in the ifland. It would alfo have become, perhaps, the richeft, and the moft populous, if the harbour, fmall as it is, had been kept in order. At prefent it is only practicable for the barks of the country; fhips remain in the road, but rarely anchor here; and thus Retimo, which, from its pofition, the abundance of oil which is collected in its vicinity, and the other productions of its territory, might be an important place of trade, has, as well as Candia, feen a part of its population pafs to Canea. Its prefent population, fays Olivier, confifts of from 5 to 6000 inhabitants, half Greeks, half Turks: the Jews here are not fo numerous as at Candia.

This town, weakly defended, was plundered and ravaged by the Turks, as far back as the year 1572, while Selim II. was caufing the fiege of Famagufta, in Cyprus, to be pufhed on with vigour; but it was not till the reign of Ibrahim, in 1645, that the Venetians were driven from it for ever; 40 miles W. of Candia. N. lat. 35° 20′. E. long. 24° 21′.

The province of Retimo is one of the beft cultivated and moft productive of the ifland; it furnifhes a great deal of oil, a little barley and wheat, and a tolerably large quantity of wine. The rifing grounds and hills which fkirt the fhores of Armiro are almoft all covered with vines. On the neareft mountains which lie to the fouth, is a foreft of common and native oaks, maples, and carob-trees, into which the inhabitants of Retimo come to cut the wood, of which they ftand in need. To the fouth of Retimo are the two provinces of Aïon-Vaffali and Amuri, the only ones that are comprifed in this pachalic; they furnifh wheat, barley, oil, and fome fruits. The former, fituated to the N.W. of the other, furnifhes, befides, excellent cheefe, which is confounded in trade with that of Sphachia. The Greeks are more numerous than the Turks in the provinces of Aïon-Vaffali and Amuri. Olivier and Sonnini.

RETINA, in *Anatomy*, a membrane of the eye, formed by the expanfion of the optic nerve, and conftituting the immediate organ of vifion. See EYE.

RETINA, in *Optics*. The retina is ufually fuppofed to be the great organ of vifion, which is effected by means of the rays of light reflected from each point of the objects refracted in their paffage through the aqueous, vitreous, and cryftalline humours, and thus thrown on the retina, where they paint the image of the object; and where they make an impreffion, which is continued thence, by the fine capillaries of the optic nerves, to the fenfory. See EYE and VISION.

Indeed, whether the retina, or the choroides, be the principal organ of vifion, and that on which the images of objects are reprefented, has been much controverted between feveral members of the Royal Academy; particularly Meffrs. Mariotte, Pecquet, Perrault, Mery, and de la Hire. Mariotte firft referred vifion to the choroides, and was feconded by Mery; the reft afferted the caufe of the retina.

The retina was always judged to have all the characters of the principal organ. It is fituated in the focus of the refraction of the humours of the eye; and of confequence receives the vertices of the cones of rays, proceeding from the feveral points of objects. It is very thin, and confequently very fenfible. It has its origin from the optic nerve, and is itfelf wholly nervous; and it is the common opinion, that the nerves are the vehicles of all fenfations. Laftly, it communicates with the fubftance of the brain, where all fenfations terminate.

As to the choroides, its ufe was fuppofed to be to ftop the rays, which the extreme tenuity of the retina fhould let pafs; and to do the fame office with refpect to the retina, which the quickfilver does to a looking-glafs; efpecially in thofe animals in which it is black.

But from an experiment of a cat plunged into water, M. Mery conceived a different opinion. (See PUPIL.) He obferved the retina to difappear abfolutely on that occafion, as well as all the other humours of the eye; while the choroides ftill appeared diftinctly, and even with all the lively colours which it has in that animal. Hence, he concluded, that the retina was as tranfparent as the humours, but the choroides opaque; confequently the retina was not a proper inftrument to terminate and ftop the cones of rays, or to receive the images of objects; but that the light muft pafs through it, and could only be ftopped on the choroides; which therefore would become the principal organ of vifion. The black colour of the choroides in man is extremely favourable to this opinion; the principal organ fhould feem to require, that the action of the light fhould terminate on it as it arrives; which it is certain it here does in the black, that abforbs all the rays, and reflects none; and it fhould alfo feem neceffary, that the action of the light fhould be ftronger on the organ of fight than any where elfe: now it is certain that the light, being received and abforbed in a black body, muft excite a greater vibration there than any where elfe; and hence it is that black bodies are kindled by a burning-glafs much fooner than white ones.

The fituation of the choroides behind the retina is another circumftance on its fide; M. Mery having obferved the fame pofition of the principal organ behind a mediate organ in the other fenfes, which makes an happy analogy. Thus the cuticle extended over the fkin is the mean organ of feeling; but the cutis underneath is the principal organ. The like is obferved in the ear, nofe, &c.

The retina, therefore, fhould feem a kind of mediate or fecondary organ, ferving to break the too ftrong impreffion of the light on the choroides, or to preferve it; which is the ufe afcribed to the cuticle. Add to all this, that the retina is infenfible, as having its origin from the medullary fubftance of the brain, which is fo too; and the choroides, on the contrary, is very fenfible, as arifing from the pia mater, which is certainly fenfible in a great degree.

This laft argument being doubted of, M. Mery was engaged to prove it; which he did before the Royal Academy, where he fhewed that the optic nerve is not compofed, like the other nerves, of fibres; that it is only a train of the medulla inclofed in a canal, out of which it is eafily feparable.

This ftructure of the optic nerve, hitherto unknown, fhews that the retina can be no membrane; it is only a dilatation of the medulla, inclofed under two membranes; and a pith or medulla feems no proper fubftance to be the feat of fenfation. It can fcarcely ferve for any thing but to filtrate the fpirits neceffary for the action of vifion. The vibration, by which the fenfation itfelf is effected, muft be made on a part more folid, more firm, and more fufceptible of a brifk impreffion.

For other arguments in favour of the choroides being the feat of vifion, fee CHOROIDES.

RETINA, *Paralytic*, and *Difeafed*. See GUTTA SERENA.

RETINACULUM, the name of a chirurgical inftrument ufed in caftration, and in the operation for a hernia, to prevent the inteftines from falling into the fcrotum.

RETINARIA, in *Botany*, was fo called by Gærtner, from *rete*, a net, or rather more immediately perhaps from the

the anatomical word *retina*, applied to the nervous network of the eye. This genus was founded, by the above author, on a fruit given him by profeffor Hermann, and faid to belong to a climbing fhrub of the Mauritius. So nearly do Gærtner's plate and defcription approach to the fruit of *Gouania domingenfis*, that we have no doubt of their belonging to fome fpecies of the fame genus; probably to one that we have defcribed in our article GOUANIA, though, poffeffing none but the *domingenfis* in fruit, we cannot exactly appropriate Gærtner's fynonym. He feems not to have been acquainted with the fruit of a *Gouania*.

RETINASPHALTUM, in *Mineralogy*, a name given to an inflammable kind of refinous fubftance, accompanying Bovey coal. It has a pale brown ochre-yellow colour, is very brittle, and breaks with a vitreous fracture. Its fpecific gravity is 1.135. When held in the hand for fome time, it emits a flightly refinous fmell, but when burned it has a fragrant odour; at laft the fmell is bituminous. On the firft application of heat it melts and fmokes, and then burns with a bright flame. When the melted mafs is cooled, it is black and brittle, and breaks with a glaffy fracture. It is not acted on by water, but is partly diffolved by alcohol, potafh, and nitric acid; the diffolved portions having the properties of a refin; the undiffolved of afphaltum. It was analyfed by Mr. Hatchett, and is compofed of

55 Refin,
41 Afphaltum,
3 Earths.

A fimilar fubftance occurs in the wood coal at Cologne, and was alfo recently difcovered in making the excavation for the Tunnel at Highgate. It may be doubted, however, whether thefe fubftances are more entitled to be ranked among minerals than the other vegetable matters found in alluvial ground.

RETINUE, RETINENTIA, the attendants or followers of a prince, or perfon of quality, chiefly in a journey.

In *Law*, thofe perfons are properly faid to be of a nobleman's retinue, who belong to him in quality either of fervants or retainers.

RETIRADE, in *Fortification*, a kind of retrenchment made in the body of a baftion, or other work, which is to be difputed inch by inch, after the firft defences are difmantled. It ufually confifts of two faces, which make a re-entering angle. When a breach is made in a baftion, the enemy may alfo make a retirade, or a new fortification behind it.

RETIRED FLANK. See FLANK.

RETIRED *Lift*, a lift on the marine eftablifhment, on which fuperannuated officers are placed.

In the Eaft India fervice, the company have refolved that a military officer, after 20 years' actual fervice in India, who comes to Europe upon leave, may be allowed to retire on the pay of his rank, provided he fignifies his intention of fo doing, within 20 months after his arrival. Officers on leave who are defirous of retiring, and who declare their intention to that effect, within 12 months from their arrival, will be permitted to retire on the pay of the rank to which they may be intitled at that period. An officer having completed 22 years' refidence in India will be allowed to retire on the full pay of his rank, directly on his leaving India.

RETMANDORF, or RADOVELZA, in *Geography*, a town of the duchy of Carniola, on the Save; 52 miles W. of Cilley. N. lat. 46° 22'. E. long. 14° 5'.

RETONVILLER, a town of France, in the department of the Somme; four miles N.E. of Roye.

RETORBIO, a town of Italy, in the Pavefe; 14 miles S. of Pavia.

RETORNO *Falfo Brevium*, in *Law*. See FALSO.

RETORNO *Habendo*, &c. See RETURNO *habendo*, and REPLEVIN.

RETORT, RETORTA, in *Chemiftry*, a kind of crooked matrafs, or a round bellied veffel, made of earth, glafs, or metal, with a flender crooked beak or neck, to which the recipient is to be faftened.

From this form this veffel has been probably called a *retort*. The moft capacious part is called the belly; its upper part the arch or roof of the retort; and the bent part, which makes with the belly an angle of about fixty degrees, is the neck; and the paffage from the belly to the neck fhould be free and wide, and gradually diminifhing to the extremity of the neck or mouth of the retort. Retorts differ in form and materials; their bellies are generally round; fome of them are oblong, and fhaped like a cucurbit, and thefe are called *Englifh* retorts. They are preferable for the diftillation of matters which are fubject to fwell, and to pafs into the receiver before they be decompofed.

A retort, which has a little hole pierced in its roof, is called a *tubulated* retort. This hole muft be capable of being exactly clofed with a ftopper of proper materials. Retorts of this kind are employed in diftillations, where fome matter muft be introduced into the retort after the receiver is joined to it, as in the diftillation of fmoking marine acid, and in the operations for procuring the feveral kinds of clyffus.

When the retort is of glafs, it is ufually covered with a lute of loam, &c. an inch thick, to enable it to bear the fire the better; and it is ufed for all operations which require a lefs heat than is fufficient for its fufion. Earthen retorts are neceffary when great heat is requifite, as in the preparation of phofphorus.

The retort feems to draw fpirits and oil from woods, gums, minerals, earths, and other matters which require a ftrong fire.

The retort is a kind of compendium or improvement on the cucurbit and bolt-head; anfwering all the purpofes of both, without the affiftance of a capital or head, which the other require.

The quantity of air arifing from fome fubftances is apt to burft glaffes in diftilling; Dr. Browne Langrifh has, therefore, given us a new contrivance of applying receivers to retorts, by which fuch accidents may be prevented. To his firft receiver he adapts a fecond, inferted into an opening at the top of the firft, in order to give more room to the rarefied and new generated air. To an opening at the bottom of each of thefe receivers, he fixes a bottle, tied on clofe by means of a bladder, fo that they may be removed at any time, and another inftantly placed in their room; by which means very little of the fteam will efcape. He alfo ties on a bladder to an opening, or upper neck of the fecond recipient; and this bladder being much thinner and weaker than any of the glaffes, will always give way firft, and prevent their burfting. And even when there is the greateft danger of this accident, the fmalleft pin-hole made through the top of the bladder, as foon as the fumes begin to rife, will be fufficient to let out the air as faft as it is generated. See Philof. Tranfact. N° 475. fect. 3. where we have a figure of the whole apparatus. For a farther account of the retort, and the ufes to which it is applied; fee DISTILLATION and LABORATORY.

RETORTION, in *Political Economy*. When a fovereign is not fatisfied with the manner in which his fubjects are treated by the laws and cuftoms of another nation, he is at liberty to declare, that he will treat the fubjects of that nation in the fame manner as his are treated. This is what is is called the "law of retortion;" in which there is nothing that is not conformable to juſt and ſound politics; for no one can complain of being treated as he treats others. This law of retortion may alſo take place with regard to certain regulations, of which we have no right to complain, and which we are even obliged to approve, though it is proper to guard againſt their effects, by imitating them. Such are the orders relating to the exportation of certain commodities or merchandize. It is alſo frequently not convenient to make uſe of retortion; in this reſpect we ought to follow the dictates of prudence.

RETOW, in *Geography*, a town of Samogitia; 12 miles W. of Medniki.

RETRACTATION, Retractatio, the act of unſaying what a perſon had ſaid or written.

Galileo made a public retractation of his doctrine of the world, De Mundo, after its being cenſured and condemned by the pope. See Copernicus and Galileo.

Among St. Auguſtine's works is a book of "retractations;" where, however, the word is to be underſtood in a new ſenſe; not as if he recanted or unſaid any thing he taught, but only treated of the ſame matter, or handled the ſame ſubject, a ſecond time. This ſenſe the word will very well bear; being a compound of *re, again,* and *tracto, I handle, treat of.*

RETRACTION, Retractio, formed from *retrahere, to draw back,* in *Anatomy,* the contraction or ſhortening of a part. A retraction of the nerves takes away the uſe of the limbs.

RETRACTS, among *Horſemen,* pricks in a horſe's feet, ariſing from the fault of the farrier in driving nails that are weak, or in driving them ill-pointed, or amiſs.

Theſe, unleſs timely prevented, feſter, and prove very dangerous. When the farrier, in ſhoeing, perceives the horſe to ſhrink at every blow on the nail, it is a ſign of a retract, and the nail is to be pulled out again; which is done without any harm.

When the horſe halts immediately after he is ſhod, it is concluded ſome of the nails preſs the veins, or touch him in the quick.

To find where the grievance lies, they knock the nails round with a hammer, till the horſe's ſhrinking upon hitting a particular nail diſcovers the place.

Some farriers give this as a rule, that throwing water on the hoof, the place where he is hurt will be dry ſooner than any of the reſt. The places where the horſes are moſt uſually pricked, are, the heel in the fore-foot, and the toe in the hind-foot.

RETRAHENS, in *Anatomy,* a muſcle of the external ear. See Ear.

RETRAXIT, in *Law,* is where the plaintiff comes into court in perſon, alone, or with the defendant; and declares he will proceed no farther in his action.

A retraxit is peremptory, and a perpetual bar, and may be pleaded as ſuch to the plaintiff in the ſame action for ever. See Nonsuit.

RETREAT, in *Ornamental Gardening,* any ſort of erection, place, or convenience, formed in gardens or pleaſure grounds for the purpoſe of recreation and amuſement. Theſe are of very different kinds, according to the nature of the particular grounds or gardens, their circumſtances, and ſituations; as covered, open, or in other forms, as the taſte of the proprietor or deſigner may direct. They may be made either in the different quarters, centre parts, angles, or other places of theſe ſituations, or formed in the range of hot-houſes, as is the caſe in ſome inſtances. The particular forms, deſigns, and means of conſtruction of them, are ſo various, but, for the moſt part, ſo well known, that it is unneceſſary to give any deſcription of them in this place. Thoſe of the more ornamental kind ſhould, however, in general, be contrived ſomewhat in conformity to the ſtyle of the ground, garden, place, and proprietor; being furniſhed from deſigns of great diverſity and number, as well as of various degrees of elegance, from that of the ſimple bower of honeyſuckle, hop, or vine, twined upon bent poles, to the Grecian porch or temple of the fineſt ſort of maſonry. Great caution is, however, required in the introduction of theſe ſorts of ornamental erections into gardens of the culinary kind. And in them, as with every thing elſe which relates to them, uſe, Mr. Loudon ſuppoſes, ſhould be the prevailing idea; and that, as *uſe* and *beauty* go hand in hand, the moſt vulgar objects may be dignified by the judicious introduction of elegance. A garden of the kitchen kind, though unmixed with productions purely ornamental, is ſtill, it is thought, a pleaſing ſcene, becauſe full of *utility* and *animation,* and conſtantly varying from the practice of cultivation, as well as from the ſeaſons. It is conſequently very generally reſorted to at moſt times of the year, but eſpecially in the early ſpring months. Of courſe, in a climate ſo very variable as this, wherever the walks are frequently made uſe of at ſuch a ſeaſon, there ſhould, it is ſaid, be covered retreats or places for retiring to, which ſhould correſpond with the whole of which they are conſpicuous parts or portions. In this way they may conſtantly be made to harmonize with the different objects around them.

Retreat, in *War,* the retiring or moving back again of an army, or part of it.

We ſay, to ſound a retreat, to ſecure a retreat, &c.

What they call a retreat in the armies, is really a flight; only a flight made by deſign, and with conduct.

The ſkill and ability of the general is known by his retreats more than his engagements. The retreat of the ten thouſand Greeks under the command of Xenophon, has been admired in all antiquity.

The three moſt celebrated retreats of modern times have been general Moreau's retreat in 1796, that of Prague, and that of general Macdonald in Italy.

Retreat, *Chequered, Rétraite en échiquier,* Fr. is ſo called from the ſeveral component parts of a line or battalion, which alternately retreat and face in the preſence of an enemy, exhibiting the figures of the chequered ſquares upon a cheſs-board. In the "General Rules and Regulations," (part 4.) it is judiciouſly obſerved, that all manœuvres of a corps retiring, are infinitely more difficult to be performed with order, than thoſe in advancing. They muſt be more or leſs accompliſhed by chequered movements; one body by its numbers or poſition, facing and protecting the retreat of another; and if the enemy preſſes hard, the whole muſt probably front in time and await him; as the ground narrows or favours, different parts of the corps muſt double; mouths of defiles and advantageous poſts muſt be poſſeſſed; by degrees the different bodies muſt diminiſh their fronts, and throw themſelves into column of march when it can be done with ſafety.

The chequered retreat by the alternate battalions or half battalions of a line going to the rear, while the others remain halted, cover them, and in their turn retire in the ſame manner, is the quickeſt mode of refuſing a part of a corps to the enemy, and at the ſame time protecting its movement, as long as it continues to be made nearly parallel to the firſt poſition.

In the chequered retreat the following rules muſt be obſerved: The battalions of the diviſion neareſt to the enemy, will form flanks as ſoon as there is nothing in their front to cover them; but the other diviſions will not have any flanks except to the outward battalion of each. The battalions always paſs by their proper intervals, and it is a rule in retiring, that the left of each ſhall always paſs the right of the neighbouring one. Whatever advantages the ground offers, thoſe advantages muſt be ſeized, without too critical an obſervance of intervals, or minute adherence to the determined diſtance of each retreat. The diviſion next the enemy muſt paſs in front, through the intervals of the diviſion immediately behind, and any battalion, that finds it neceſſary, muſt incline for that purpoſe. The retiring diviſion muſt ſtep out, and take up no more time than what is abſolutely required to avoid confuſion. The diviſion neareſt the enemy fires by platoons ſtanding; the flanks of its battalions only fire when the enemy attempts to puſh through the intervals. When that diviſion retires, it fires on, ſkirmiſhes by men detached from its light company, if preſent, or from platoons formed of rear rank men of one or two of the companies, and placed behind the flanks of the battalions. But ſhould any of its battalions be obliged to halt and to fire, a ſhorter ſtep muſt then be taken by the line; and ſhould the enemy threaten to enter at any of its intervals, beſides the fire of its flanks, ſuch platoons of the line behind it, as can with ſafety, muſt give it ſupport.

Retreat is a beat of the drum in the evening, at the firing of a piece called the evening-gun, at which the drum-major, with all the drums of the battalion, except ſuch as are upon duty, beat round the regiment; the drums of the quarter-guards, of the general-guards, and all other ſmall-guards, do likewiſe beat; the trumpets at the ſame time ſounding at the head of their reſpective troops. This is to warn the ſoldiers to forbear firing, and the ſentinels to challenge, till break of day, that the reveille is beat.

The retreat is likewiſe called *ſetting the watch.*

In fortified places, this is a ſignal for the inhabitants to come in before the gates are ſhut. See Drum.

Retreat, or *Relay*, in *Maſonry*, denotes a little receſs or diminution of the thickneſs of a wall, rampart, &c. in proportion as it is raiſed.

The retreat is properly the diminution of a wall, withoutſide, or the contraction of its upper courſes more than the foundation. Where the foundation is very large, they uſually make two or three retreats. Parapets are always built with retreats.

RETRENCHMENT, in a general ſenſe, literally ſignifies the cutting off or taking from a thing: in which ſenſe it coincides with ſubtraction, diminution, &c.

The word is French, *retrenchment*, formed of *re*, and *trencher, to cut.*

Retrenchment, in *Architecture*, *Carpentry*, &c. is uſed not only for what is cut off from a piece when too large, in order to a better proportioning it, or ſome other convenience, but alſo for the projectures taken out of ſtreets, public ways, &c. to render them more even, and in a line.

Retrenchment, in *War*, denotes any kind of work caſt up to ſtrengthen or defend a poſt againſt the enemy.

Such are ditches with parapets, gabions, faſcines, &c. for a covering, &c.

The enemy came with deſign to oblige them to raiſe the ſiege; but could not force the retrenchments.

Retrenchments are either *general* or *particular.*

General retrenchments are a kind of new defence made in a place beſieged, to cover the defendants, when the enemy becomes maſter of a lodgement on the fortification, that they may be in a condition of diſputing the ground inch by inch, and of putting a ſtop to the enemy's progreſs, in expectation of relief; as, if the beſiegers attack a tenaille of the place, which they judge the weakeſt, either by its being ill flanked, or commanded by ſome neighbouring ground; then the beſieged make a great retrenchment, incloſing all that part which they judge in moſt danger. Theſe ſhould be fortified with baſtions and demi-baſtions, ſurrounded by a good ditch countermined, and higher than the works of the place, that they may command the old works, and put the beſiegers to infinite trouble in covering themſelves.

Particular retrenchments, or retrenchments within a baſtion, (*retranchemens dans un baſtion*, Fr.) muſt reach from one flank to another, or from one caſemate to another. It is only in full baſtions that retrenchments can be thrown up to advantage. In empty baſtions you can only have recourſe to retirades, or temporary barricadoes above the ramparts. The aſſailants may eaſily carry them by means of hand grenades, for theſe retrenchments never flank each other. It is neceſſary to raiſe a parapet, about five or ſix feet thick, before every retrenchment. It muſt be five feet high, and the ditches as broad and as deep as they can be made. There muſt alſo be ſmall mines run out in various directions, for the purpoſe of blowing up the aſſailants, ſhould they attempt to force the retrenchments.

Retrenchment is more particularly uſed for a ſimple retirade made on a horn-work or baſtion, when it is intended to diſpute the ground inch by inch. See Retirade.

It is uſually a re-entering angle, whoſe faces flank each other; and is fortified with ditches, parapets, gabions, &c.

RETRIBUTION, Retributio, a handſome preſent, gratuity, or acknowledgment, given in lieu of a formal ſalary or hire, to perſons employed in affairs that do not ſo immediately fall under eſtimation, nor within the ordinary commerce in money.

Thoſe who miniſtered at the altar anciently lived on retributions, which they received for the ſervices they did the church. But theſe retributions were afterwards judged proper to be fixed to preciſe ſums.

RETRIEVE, Retrouver, to recover, get again, or repair a thing loſt or damaged.

To retrieve, in *Falconry*, ſignifies to bring or find partridges again, which have been once ſprung before.

RETROACTIVE, compounded of *retro, backwards,* and *ago, I act,* in *Law*, that which has an influence or effect on time paſt.

New laws and ſtatutes, we ſay, have no retroactive effect; that is, they have no force or effect as to what is already paſſed; nor can be alleged as rules for any thing done before their promulgation. Their authority is wholly as to what is to come.

Indeed we have ſome inſtances of laws that have a retroſpect to retroaction, *i. e.* are made with expreſs deſign to extend to things already paſt. Theſe we uſually call laws *ex poſt facto.*

RETROCESSION, Retrocessio, the act of going backwards, more uſually expreſſed by *retrogreſſion*, or *retrogradation.*

Retrocession *of the Equinox.* See Precession.

Retrocession *of Curves*, &c. See Retrogradation.

RETROGRADATION, or Retrogression, the act or effect of a thing moving backwards.

Retrogradation, in *Aſtronomy*, is an apparent motion of the planets, in which they ſeem to go backwards in the ecliptic, and to move contrary to the order or ſucceſſion of the ſigns.

When a planet moves *in conſequentia*, *i. e.* towards the following ſigns, or according to the order of the ſigns, as from

Aries to Taurus, from Taurus to Gemini, &c. that is, from weſt to eaſt, it is ſaid to be direct.

When it appears for ſome days in the ſame point of the heavens, it is ſaid to be *ſtationary*.

And when it goes *in antecedentia*, *i. e.* towards the antecedent ſigns, or contrary to the order of the ſigns, *viz.* from eaſt to weſt; it is ſaid to be *retrograde*.

The ſun and moon always appear direct. Herſchel, Saturn, Jupiter, Mars, Venus, and Mercury, ſometimes direct, ſometimes ſtationary, ſometimes retrograde.

The ſuperior planets are retrograde about their oppoſition with the ſun; the inferior ones about their conjunction. The intervals of time between two retrogradations of the ſeveral planets are unequal.

Theſe changes of the courſes and motions of the planets are not real, but only apparent: when viewed from the centre of the ſyſtem, *i. e.* from the ſun, they appear always uniform and regular. The inequalities ariſe from the motion and poſition of the earth from which they are viewed, and are thus accounted for:

Suppoſe P N O (*Plate* XIX. *Aſtronomy*, *fig.* 12.) a portion of the zodiac, A B C D the earth's orbit, and E M G H Z the orbit of a ſuperior planet, *e. gr.* Saturn; and ſuppoſe the earth in A, and Saturn in E, in which caſe he will appear in the zodiac at the point O. If now Saturn remained without any motion, when the earth arrives at B, he will be ſeen in the point of the zodiac L, and would appear to have deſcribed the arc O L, and to have moved according to the order of the ſigns from weſt to eaſt. But becauſe, while the earth is paſſing from A to B, Saturn likewiſe moves from E to M, where he is ſeen in conjunction with the ſun, he will appear to have deſcribed the arc O Q greater than that O L. In this ſtate the planet is direct, and its motion is from weſt to eaſt, or according to the order of the ſigns. And its motion, now that it is in conjunction with the ſun, and moſt remote from us, is quicker than at any other time.

The earth arriving in C, while Saturn deſcribes the arc M G, he will be obſerved in the zodiac at R. But the earth being advanced to K, and Saturn to H, ſo that the line K H, joining the earth and Saturn, be for ſome time parallel to itſelf, or nearly ſo, Saturn will be ſeen all that time in the ſame point of the zodiac at P, and with the ſame fixed ſtars; and is therefore at this time ſtationary.

But the earth being come to D, and Saturn arrived in oppoſition to the ſun in Z, he will appear in the zodiac in V, and will ſeem to have been retrograde, or to have gone backwards through the arc P V. Thus the ſuperior planets, on optical conſiderations, are always retrograde, when in oppoſition to the ſun.

The arc which the planet deſcribes while thus retrograde, is called the *arc of retrogradation*.

The arcs of retrogradation of the ſeveral planets are not equal. That of Saturn is greater than that of Jupiter; that of Jupiter than that of Mars, &c.

Retrogradation *of the Nodes*, is a motion of the line of the nodes, by which it continually ſhifts its ſituation from eaſt to weſt, contrary to the order of the ſigns; completing its retrograde circulation in the compaſs of about nineteen years: after which time, either of the nodes, having receded from any point of the ecliptic, returns to the ſame again. See Nodes.

Retrogradation *of the Sun*. When the ſun is in the torrid zone, and has his declination A M (*Plate* XIX. *Aſtronomy*, *fig.* 13.) greater than the latitude of the place A Z, but either northern or ſouthern as that is, the ſun will appear to go backwards, or to be retrograde both before and after noon. This can never happen, without the tropics, in a natural way.

For, draw the vertical circle Z G N to be a tangent to the ſun's diurnal circle in G, and another Z O N through the ſun's riſing, in O, it is evident all the intermediate vertical circles cut the ſun's diurnal circle twice; firſt, in the arc G O, and the ſecond time in the arc G I. Wherefore, as the ſun aſcends through the arc G O, it continually arrives at farther and farther verticals. But as it continues its aſcent through the arc G I, it returns to its former verticals; and, therefore, is ſeen retrograde for ſome time before noon. The ſame it may be ſhewn, after the ſame manner, it does for ſome time after noon. Hence, as the ſhadow always tends the oppoſite way to that of the ſun, the ſhadow will be retrograde twice every day in all places of the torrid zone, where the ſun's declination exceeds the latitude.

Retrogradation, or *Retrogreſſion*, in the *Higher Geometry*, is the ſame with what we otherwiſe call *contrary flexion*. See Flexure and Inflexion.

The general rule given by the marquis de l'Hôpital, for finding the point of reflection in curves whoſe ordinates are parallel, is the ſame as that for finding the point of contrary flexure, and conſiſts in taking the ſecond fluxion of the ordinate of the curve, and ſuppoſing it nothing or infinite: but this rule admits of many exceptions. See Maclaurin's Flux. b. i. c. 9. and b. ii. c. 5.

RETROGRADE, Retrogradus, formed from *retro*, *backwards*, and *gradior*, *I go*, ſomething that goes backwards, or in a direction contrary to the natural one.

If the eye and the object both move the ſame way, but the eye much faſter than the object, the object will appear to be retrograde, *i. e.* to go back, or to advance the contrary way from what it really does.

Hence it is that the planets, in ſome parts of their orbits, appear to be retrograde.

Retrograde order, in matters of numeration, is when, in lieu of accounting 1, 2, 3, 4, we count 4, 3, 2, 1.

Retrograde *Verſes* are ſuch as give the ſame words, whether read backwards or forwards: called alſo *reciprocal verſes*, and *recurrents*. Such is

"Signa te ſigna; temere me tangis et angis."

RETROGRADO, Ital. in *Muſic*, a retrograde motion of a melody, or ſubject of canon. This motion is ſometimes termed by the Italians, *imitatione cancherizante*; imitation of the movement of a crab-fiſh. See Canon.

RETROGRESSION, or Retrocession, the ſame with retrogradation.

RETROMINGENTS, compounded of *retro*, *backwards*, and *mingo*, *I make water*, in *Natural Hiſtory*, a claſs or diviſion of animals, whoſe characteriſtic is, that they ſtale backwards, both males and females. Such are lions, cats, &c.

RETROPANNAGIUM, Retropannage, in our *Ancient Law Books*, *after-pannage*; or what is left when the beaſts have done, or eaten the beſt. See Pannage.

"Et debent habere retropannagium a feſto Sancti Martini uſque ad feſtum Pur. Beatæ Mariæ." Petit. in Parl. temp. Edw. III.

RETROSPECT, a look or view backwards. See Retroactive.

RETROVERSIO Uteri, in *Surgery*. The womb is ſubject to two particular changes in the poſition of its fundus, which may be diſplaced either forwards or backwards. The firſt caſe, ſometimes termed *anteverſion*, is the leaſt frequent; the ſecond, or *retroverſion*, is more often met with. In the inſtance of anteverſion, when the ſurgeon makes an

 examina-

examination with his finger, he finds the fundus of the uterus inclining forwards towards the os pubis over the fundus of the bladder; while the os tincæ is carried backwards towards the facrum, upon the middle of the rectum, fometimes fo high up that it can hardly be reached with the finger. The patient has generally a conftant inclination to make water; preffure juft above the pubes always gives her confiderable pain; whenever fhe gets up to walk, fhe is confcious of a hard fubftance falling upon the bladder, and obliging her to empty it; and, when fhe lies down upon her back, fhe feels the fame hard body flip back again. In one example, a patient had fuch pain in the abdomen and foft parts, that fhe could fcarcely move.

In general, the anteverfion of the womb may eafily be remedied. The patient being laid upon her back, which is to be fomewhat raifed up, the furgeon is to apply his hand above the pubes, and make preffure there, by which means the fundus uteri will be forced backwards, and the os tincæ inclined forwards into its natural fituation. A recurrence of the difplacement is to be prevented by the application of a peffary, which will fupport the os tincæ. The patient is to be kept for a certain time upon her back in bed, and a tight bandage fhould always be put round the body juft over the os pubis. The uterus by degrees commonly becomes fixed again in its right pofition, fo that the ufe of the peffary can be difcontinued. The inftrument muft not be left off too foon, however, left a relapfe fhould be the confequence.

In the retroverfion, the pofition of the womb is altered in a manner precifely the reverfe of what occurs in the foregoing cafe. The os tincæ lies towards the pubes; while the fundus uteri is carried towards the facrum, and is generally funk fo far down betwixt the vagina and the rectum, as to occafion, at the pofterior part of the former canal, a protuberance, which clofes it, and which at the fame time compreffes the rectum in fuch a manner, that the patient cannot void her feces, nor can clyfters be adminiftered. As in this preternatural pofition of the uterus, the bladder and meatus urinarius are unavoidably difplaced, the cafe is always complicated with a retention of urine, which is the more afflicting, as it is ufually very difficult, and even impracticable, to introduce a catheter. The opening of the meatus urinarius is fometimes drawn fo high up, that it is actually higher than the pubes. Hence, the anterior parietes of the vagina are conftantly very much ftretched. When the retention of urine has lafted a certain time, the os tincæ above the pubes cannot be reached nor touched with the end of the finger. In this circumftance the bladder forms, beneath the os tincæ, a large fwelling, which hinders the finger from feeling the latter opening. The patient always fuffers exceffive pain, which not unfrequently refembles that of labour, and arifes partly from the impediment to the evacuation of the urine, and partly from the difplaced condition of the parts. The diforder, therefore, has often been mifunderftood, the patient's fufferings being regarded as labour-pains, and delivery expected. Indeed, when the complaint is not fpeedily removed, a mifcarriage is the confequence. The cafe is frequently attended with fever and inflammation.

The retroverfion of the uterus has never been obferved, except in pregnancy, and always in the fecond, third, or fourth month of that ftate. It is moft apt to occur in fuch women as have a wide pelvis. Fat fubjects are more liable to the diforder than thin. It is obferved to be brought on by bodily exercifes and exertions, as, for inftance, by violent vomiting, falls, the lifting of heavy burdens, &c. But, Richter thinks it unlikely, that the cafe fhould arife and be fuddenly produced by thefe caufes alone. How, he afks, could the gravid, round, diftended uterus be thus fuddenly difplaced, and become depreffed betwixt the rectum and the vagina? He conceives it probable, that a predifpofition to diforder, or rather an incipient ftage of it, muft have exifted. He thinks it likely, that the occurrence of the complaint may be promoted by repeatedly neglecting to make water, and by the confequent diftention of the bladder, whereby not only the fundus uteri is preffed towards the facrum, but alfo the cervix becomes drawn upwards. Richter believes, that a fmall degree of retroverfion, that has exifted a good while, may only be increafed by the caufes already hinted at, fo as to excite notice; and that the fundus of the uterus may now foon be forced by the efforts, refembling thofe of labour, fo far down between the vagina and the rectum, that all thefe parts become as it were adherent together. The foregoing ftatement Richter thinks the more likely to be correct, inafmuch as cafes have actually been obferved, where patients have experienced various flight complaints a confiderable time before the retroverfion was known to exift; but which complaints might be afcribed to the incipient ftage of that fort of difplacement of the uterus. How it happens, that retroverfion of this organ is only met with in the early months of pregnancy, is eafy of comprehenfion. The retroverfion is promoted by the weight of the gravid uterus. During the latter half of the period of geftation, however, the uterus is too large to be capable of defcending betwixt the vagina and rectum; and the occurrence of retroverfion, except in pregnancy, is what can hardly be conceived.

The furgeon fhould always endeavour to put the retroverted uterus, as foon as poffible, into its natural pofition again. The longer the retroverfion has lafted, the more difficult it is of removal, and the more preffing are the dangers, of which there is caufe for apprehenfion. The moft urgent peril arifes from the retention of the urine, and the ftoppage of evacuations from the bowels. The longer thefe functions are obftructed, and the more the urine and feces accumulate, the more violent do the painful labour-like efforts become, whereby the fundus uteri is continually preffed more and more deeply downwards. Befides, the diftention of the rectum and bladder operates itfelf as an immediate impediment to the reduction of the uterus. Patients have been known to lofe their lives in confequence of the bladder giving way. Sometimes abortion happens; and very often the confequences of fuch an event are favourable; the urine foon afterwards being fpontaneoufly voided, and all the complaints fubfiding. (Saxtorph, Collectanea Havnienfia, vol. ii.) The diforder, however, has been known to continue eleven days, and yet admit of being removed in the moft favourable manner.

In difficult cafes, the reduction of a retroverted uterus may be facilitated by previoufly emptying the rectum and bladder; an object which is frequently practicable. The diftended bladder not only renders the reduction difficult, but is attended with fome danger of that organ burfting in the operation, which often requires the exertion of confiderable force, efpecially when the bladder is very much dilated. Hence, before attempting the reduction, the furgeon is called upon always to endeavour to draw off the urine. When the bladder has been emptied, the retroverted uterus fometimes fpontaneoufly returns into its natural pofition, as feveral cafes on record have proved. (Hunter and Chefton in Medical Communications, vol. ii.; Croft in London Medical Journal, vol. xi.) Such facts muft fully convince us, how much the reduction may be facilitated by drawing off the urine in the firft inftance. A catheter may frequently

frequently be introduced; but it ſhould be of the flexible ſort. A curved inflexible one will alſo ſometimes paſs, if care be taken to keep its concavity turned towards the vagina. Rotating the catheter on its axis is here a particularly uſeful plan. When the catheter cannot be paſſed, other means will ſometimes anſwer for bringing about an evacuation of the urine. In ſome caſes, the water will begin to flow out, when two fingers are introduced betwixt the pubes and os tincæ, and the latter part is preſſed towards the ſacrum. Sometimes preſſing the os tincæ downwards with the finger; on other occaſions, raiſing the fundus uteri backwards and upwards, by means of two fingers in the vagina will have the deſired effect.

When the bladder cannot be emptied in this manner, nor by the catheter, and ſhould it be very much diſtended, and the reduction of the uterus attended with great difficulty, there can be no doubt about the neceſſity of puncturing the bladder; for the immediate and moſt urgent danger ariſes from the retention of urine, and, probably, the diſtended bladder is itſelf the chief impediment to the reduction of the womb into its natural poſition. To theſe conſiderations we may add, that the paracenteſis of the bladder has been performed in theſe caſes with complete ſucceſs. (Cheſton in Medical Communications, vol. ii.) The practitioner muſt alſo endeavour to empty the rectum by means of clyſters, though, it muſt be confeſſed, their application is always attended with a degree of difficulty.

The reduction of the retroverted uterus is executed by preſſing with two fingers applied to the fundus of this viſcus. A principal obſtacle to the ſucceſs of the attempt is cauſed by the projection of the os ſacrum. Hence, it is an indication of the greateſt conſequence to remove the fundus of a retroverted uterus as far as poſſible from that bone, in order that the preceding ſort of hindrance to the reduction may be avoided. With this view the preſſure of the fingers ſhould be ſo directed as not to incline towards the prominence of the ſacrum. During the operation, the patient ſhould reſt upon her elbows and knees, as, in this poſition, the uterus will be at a greater diſtance from the ſacrum. Richter diſapproves of the plan, which ſome writers have recommended, and which conſiſts in introducing two fingers into the vagina, for the purpoſe of reaching and drawing downwards the os tincæ. He aſſerts, that ſuch part can ſeldom be reached, and, that if it could be ſo in a few inſtances, it would not admit of being drawn downwards, while the fundus is incapable of following in the ſame direction. Richter alſo obſerves, that the fundus uteri is at this period the leſs likely to be reduced, becauſe the fingers in the vagina have the effect of preſſing it towards the projection of the ſacrum.

The preſſure of the finger, whereby the fundus uteri is to be puſhed up, ſhould be directed forwards and upwards towards the navel. When the preſſure is made directly upwards, the body of the uterus is forced againſt the projection of the ſacrum, and the attempt cannot poſſibly ſucceed. Indeed, when much force is exerted, as is ſometimes requiſite, preſſure thus directed may do injury to the fœtus and the mother, and bring on abortion. It is advantageous to introduce two fingers into the rectum, with their backs towards the ſacrum, and their inſides towards the vagina; for they may then be uſed for keeping the uterus towards the navel. Perhaps it may likewiſe be adviſeable to lay two fingers on the abdomen above the pubes, in order to prevent the os tincæ from inclining upwards. Perhaps, alſo, two fingers, paſſed into the vagina, might be uſefully employed in preſſing the fundus uteri upwards. In difficult caſes, this double kind of preſſure might be abſolutely neceſſary. If the retroverted uterus ſhould not yield to the foregoing practice, an endeavour may be made, at all events, to puſh the diſplaced viſcus upwards on one ſide of the projection of the ſacrum.

In certain examples, it may be proper not to paſs the fingers into the rectum, but merely into the vagina; 1ſt, becauſe we can thus more certainly and effectually make the preſſure act upon the uterus; and 2dly, becauſe, when the poſterior parietes of the vagina are puſhed with the end of the fingers towards the ſacrum, and the upper part of this tube, ſituated betwixt the fingers and the os tincæ, is ſtretched, the vagina acts upon the uterus in a manner particularly well calculated to promote the reduction. Not more than two fingers, however, ought to be introduced, as more have the effect of dilating the vagina laterally, and preventing it from becoming tenſe in the longitudinal direction. Theden's Bemerkungen, 3 Sheil.

When this method is adopted, the uterus in general begins to yield at firſt ſlowly, and afterwards it ſuddenly returns into its natural ſituation. Sometimes the tendency to retroverſion is ſo great, that the diſorder recurs almoſt immediately after the reduction has been accompliſhed. In this circumſtance, the patient muſt wear a peſſary, until all hazard of another retroverſion is removed by the increaſe of pregnancy. (Hunter in Medical Obſervations and Enquiries, vol. iv.) Sometimes, when the bladder has been very much diſtended with urine during the continuance of a retroverſion of the womb, a retention of urine from weakneſs of the bladder will remain after the reduction of the uterus, and demand the uſe of the catheter. Richter's Anfangſgrunde der Wundarzneykunſt; Hunter in Medical Obſervations and Enquiries, vol. iv.; Cheſton, in Medical Communications, &c.

RETSCHITZ Kardasch, in *Geography*, a town of Bohemia, in the circle of Bechin; 15 miles S.W. of Tabor.

Retschitz *Rot*, a town of Bohemia, in the circle of Bechin; five miles N. of Pilgram.

RETTEN, a town of the duchy of Stiria; 12 miles W. of Friedburg.

RETTERHEIM, a town of the duchy of Wurzburg, inſulated in Wertheim; 16 miles W. of Wurzburg.

RETTERSBACH, a town of the duchy of Wurzburg; five miles S. of Gemunden.

RETTERSWALD, a town of Pruſſia, in Pomerelia; ſeven miles S.E. of Marienburg.

RETTINGBERS, a town of Hindooſtan, in Myſore; 38 miles E. of Chitteldroog. N. lat. 14° 5′. E. long. 77° 4′.

RETTLSTEIN, a town of Stiria, on the Muehr; ſix miles S.E. of Pruck.—Alſo, a mountain of Stiria; eight miles E. of Pruck.

RETTO, Ital. in *Muſic*, ſtraight forward, direct, one of the three movements of muſical notes or ſounds in melody; which are, *moto retto*, *moto contrario*, and *moto obliquo*. *Moto retto* is, therefore, a regular aſcent of the ſcale, or a part of it: as moving from the key-note to the 5th through all the intermediate ſounds, in regular order; as c d e f g, &c. Another ſpecies of movement ſeems wanting to expreſs wide intervals, ſuch as ſkips or leaps beyond the regular progreſſion, which in Latin is expreſſed by the words *per ſaltum*, and in Italian either is, or might be, called *moto de ſalto*.

RETUERTO, in *Geography*, a town of Spain, in Old Caſtile; 18 miles S. of Burgos.

RETURN, Returna, or *Retorna*, in *Law*, hath divers acceptations. As,

Return

RETURN *of Writs* by sheriffs and bailiffs, is a certificate made to the court by the sheriff, bailiff, &c. of what is done with regard to the execution of the writ directed to them.

Whence the day, on which the defendant is ordered to appear in court, and on which the sheriff is to bring in the writ, and report how far he has obeyed it, is called the return of the writ; it being then returned by him to the king's justices at Westminster. And it is always made returnable at the distance of at least fifteen days from the date or teste, that the defendant may have time to come up to Westminster, even from the most remote parts of the kingdom; and upon some day in one of the four terms, in which the court sits for the dispatch of business. See RETURNS, infra.

Such also is the *return of a commission*, which is a certificate, or answer of what is done by the commissioners to whom such commissions, precepts, mandates, or the like, are directed,

RETURN is also used in case of a replevin. If a man distrain cattle for rent, &c. and afterwards justify or avow his act, so as it is found lawful, the cattle before delivered unto him that was distrained, upon security given to prosecute the action, shall now be returned to him that distrained them. See RETURNO *Habendo*, and REPLEVY.

RETURN *of Members of Parliament*. See PARLIAMENT.

RETURN *to a Mandamus*. See MANDAMUS.

RETURNS, *Return-days*, or *days in bank*, *dies in banco*, that is, days of appearance in the court of common pleas, usually called *bancum*, or *commune bancum*, to distinguish it from *bancum regis*, or the court of king's bench, are certain days in each term peculiarly set apart for the several kinds of proceedings in any cause to be determined. These days are generally at the distance of about a week from each other, and regulated by some festival of the church. On some one of these days in bank all original writs must be made returnable, and therefore they are commonly called the returns of that term; of which every term has more or less, said by the Mirror (cap. 5. § 108.) to have been originally fixed by king Alfred, but certainly settled as early as the statute of 51 Hen. III. stat. 2. But though many of the return-days are fixed upon Sundays, yet the court never sits to receive these returns till the Monday after; and, therefore, no proceedings can be had, or judgment can be given, or supposed to be given on a Sunday. See DAY.

Hilary term has four such returns; *viz. octabis Hilarii*, eight days after Hilary day; *quindena Hilarii*, fifteen days; *crastina Purificatione*, the day after the Purification; and *octabis Purificationis*, eight days after, inclusive.

Easter term has five returns; *viz. quindena Paschæ*, fifteen days after Easter; *tres Paschæ*, three weeks after; *mense Paschæ*, the day month after Easter; *quinque Paschæ*, the day five weeks from Easter; and *crastino Ascensionis Domini*, the day after Ascension-day.

Trinity term has four returns; *viz. crastino Trinitatis*, the day after Trinity; *octabis Trinitatis*, eight days after, inclusive; *quindena Trinitatis*, fifteen days after; and *tres Trinitatis*, three weeks after.

Michaelmas term has four returns, by stat. 24 Geo. II. cap. 48, *viz. crastino Animarum*, morrow of All-Souls; *crastino Martini*, the morrow of St. Martin; *octabis Martini*, eight days after, inclusive; and *quindena Martini*, fifteen days after.

The first return in every term is, properly speaking, the first day in that term; *e. gr.* the octave of St. Hilary, which falling on the thirteenth of January, the octave, or first day of Hilary term, is the twentieth of January; and this is called the *essoign day of term*. But by reason of the *quarto die post*, the court does not sit, at the beginning of each term, for dispatch of business, till the fourth day, as in Hilary term on the twenty-third of January; and in Trinity term, by statute 32 Hen. VIII. cap. 21. not till the sixth day; which is, therefore, usually called and set down in the almanacs as the first day of *Term;* which see.

RETURN, in the *Military Language*, denotes the list of the sick, given in once a week by the surgeon to the commanding officer of a regiment.

Commissioned officers are not put in the returns, which, on that account, are but an imperfect list of the sick.

Twelve sick, in a battalion of 780 private men, is the lowest return that can be expected, even in the most healthy season and climate, as well as best quarters. Returns are often much higher, but seldom exceed seventy in a battalion.

It is to be observed, that returns include all accidents unfitting a soldier for duty; together with a general state of the army, regiment, or company. See Pringle's Observ. on the Diseases of the Army, p. 12—36.

In section V. of the articles of war, it is expressed, that every officer who shall knowingly make a false return to the king, to the commander-in-chief of the forces, or to any his superior officer authorised to call for such returns, shall, upon being convicted thereof before a general court-martial, be cashiered.

Whoever shall be convicted of having designedly, or through neglect, omitted sending such returns, shall be punished according to the nature of the offence by the judgment of a general court-martial.

Returns are to be made in the same manner of the forces in Ireland to the chief governor or governors thereof; likewise of the forces in North Britain to the officer there commanding in chief: which returns are from time to time to be transmitted to England as it shall appear best for the service.

Exact returns from Gibraltar, &c. and regiments stationed abroad, are by their respective governor or commanders *there residing*, by all convenient opportunities to be transmitted to the secretary at war, in order that the same may be laid before the king.

The life and foot-guards do not make any returns to the commander-in-chief or secretary at war, but to the king direct through their several field officers. This privilege is attached to them upon the principle of being household troops. Upon the same principle they have always, when brigaded, a general of their own attached to each brigade; on which account likewise, no other military honours than those done to their own brigade general are to be paid by them, except to a branch of the royal family, or to a commander-in-chief.

RETURN, *To*, in a military sense, to insert the names of such officers, &c. as are present or absent on the stated periods for the identification of their being with their regiments, on detachment, or absent with or without leave.

Every officer commanding a regiment or detachment, will, on his arrival from abroad, transmit to the adjutant-general's office, and to the war-office, a disembarkation retnrn, a duplicate of which he will also deliver to the general, or other officer commanding at the port at which he disembarks.

Commanding officers of regiments in South Britain, are regularly to transmit to the adjutant-general's office the following returns.

A monthly, on the 1st of each month.

A return

A return of officers, on the 14th of each month.

A weekly ſtate, to arrive on Mondays.

To the war-office.

A monthly return, on the 1ſt of each month.

A return of abſent officers, on the 14th of each month.

Every officer commanding a regiment, or detachment, on embarking for a foreign ſtation, will tranſmit an embarkation return to the adjutant-general's office, and to the war-office, a duplicate of which he will deliver to the general or officer commanding at the port from which he embarks.

On a regiment embarking, the commanding officer is to tranſmit to the adjutant-general's office, a return of the recruiting parties he purpoſes to leave in Great Britain, or Ireland, ſpecifying their ſtrength, their ſtations, and the officers by whom they are commanded; a duplicate of this return is to be tranſmitted to the inſpector-general of the recruiting ſervice in the Iſle of Wight.

All officers belonging to regiments on foreign ſtations, not actually employed on the recruiting ſervice, are to report their arrival from abroad, and the cauſe of their abſence, at the adjutant-general's office, and are to leave their addreſſes with their reſpective agents, and in caſe of their changing their places of reſidence, are immediately to notice the ſame to their agent: any officer whoſe addreſs is not with his agent, will be conſidered as abſent without leave, and guilty of diſobedience of orders.

Officers upon half pay are, in like manner, to leave their addreſſes at the war-office; particularly ſo if they ſhould leave the united kingdoms; and officers belonging to the militia are to leave their names, &c. with the ſeveral adjutants of regiments.

Commanding officers of regiments are to tranſmit to the quarter-maſter-general an half-yearly return of quarters, on the 1ſt of December, and the 1ſt of May, agreeable to the printed form; likewiſe a report of any march performed by the corps under their orders.

All returns, reports, and papers, purely of a military and public nature, which are to be ſent to the adjutant-general, are to be addreſſed, "To the Adjutant-general of the Forces, Horſe-guards, London," without adjoining his name.

All official letters from general or other officers in command, which are deſigned to be laid before his royal highneſs the commander-in-chief, are to be ſigned by the general or commanding officers themſelves.

All official letters, intended for the deputy adjutant-general, or other officers belonging to the department, are to be tranſmitted, under covers, addreſſed as above, to the adjutant-general.

To prevent an improper expence of poſtage, all official letters and returns ſent to the quarter-maſter-general, or officers in his department, are to be ſent, under covers, addreſſed "To the right honourable the Secretary at War, London;" and on the outſide of the covers is to be written, in legible characters, "Quarter-maſter General's Department."

Return, in *Building*, denotes a ſide, or part, that falls away from the foreſide of any ſtraight work.

Returns *of a Trench*, in *Fortification*, are the turnings and windings which form the lines of a trench.

Returns *of a Mine*, in the *Military Art*, are the turnings and windings of the gallery.

RETURNED *next for Purchaſe*. When vacancies occur in regiments upon foreign or domeſtic ſtations, the names of ſuch officers as intend to purchaſe muſt be inſerted in the muſter rolls; they are then ſaid *to be returned next for purchaſe*. This ſerves as a government to the ſeveral agents, and prevents the introduction of perſons into a corps they have not done duty with, to the diſparagement of thoſe who have always followed the colours. The preſent commander-in-chief is particularly ſcrupulous on this head. Every officer that is returned next for purchaſe, muſt take care to apprize his agent that the money will be lodged for that purpoſe.

RETURNING Stroke, in *Electricity*, is an expreſſion uſed by lord Mahon, (now earl Stanhope,) to denote the effect produced by the return of the electric fire into a body from which, in certain circumſtances, it has been expelled.

In order to underſtand the meaning of theſe terms, it is neceſſary to premiſe that, according to the noble author's experiments, an inſulated ſmooth body, immerged within the electrical atmoſphere, but beyond the ſtriking diſtance, of another body charged poſitively, is at the ſame time in a ſtate of threefold electricity. The end next to the charged body acquires negative electricity; the farther end becomes poſitively electrified; while a certain part of the body, ſomewhere between its two extremities, is in a natural, unelectrified, or neutral ſtate; ſo that the two contrary electricities balance each other. Moreover, it may be added, that if the body be not inſulated, or have a communication with the earth, the whole of it will be in a negative ſtate; a certain portion of its natural quantity of electricity being driven into the common maſs, by the preſſure, repulſion, or other action of the electric matter belonging to the charged prime conductor. Let us then ſuppoſe a braſs ball, which we may call A, to be conſtantly placed at the ſtriking diſtance of a prime conductor; ſo that the conductor, the inſtant when it becomes fully charged, explodes into it. Let another large conductor, which we may call the ſecond conductor, be ſuſpended, in a perfectly inſulated ſtate, farther from the prime conductor than the ſtriking diſtance, but within its electrical atmoſphere: let a perſon ſtanding on an inſulated ſtool touch this ſecond conductor very lightly with a finger of his right hand; while, with a finger of his left hand, he communicates with the earth, by touching very lightly a ſecond braſs ball fixed at the top of a metallic ſtand, on the floor, which we may call B; while the prime conductor is receiving its electricity, ſparks paſs (at leaſt if the diſtance between the two conductors is not too great) from the ſecond conductor to the inſulated perſon's right hand; while ſimilar and ſimultaneous ſparks paſs out from the finger of his left hand into the ſecond metallic ball B, communicating with the earth. Theſe ſparks are part of the natural quantity of electric matter belonging to the ſecond conductor, and to the inſulated perſon, driven from them into the earth, through the ball B, and its ſtand, by the elaſtic preſſure or action of the atmoſphere of the prime conductor; the ſecond conductor, and the inſulated perſon, are hereby reduced to a negative ſtate. At length, however, the prime conductor having acquired its full charge, ſuddenly ſtrikes into the ball B, of the firſt metallic ſtand, placed for that purpoſe at the ſtriking diſtance. The exploſion being made, and the prime conductor ſuddenly robbed of its elaſtic atmoſphere, its preſſure or action on the ſecond conductor, and on the inſulated perſon, as ſuddenly ceaſes; and the latter inſtantly feels a ſmart returning ſtroke, though he has no direct or viſible communication (except by the floor) either with the ſtriking or ſtruck body, and is placed at the diſtance of five or ſix feet from both of them. This returning ſtroke is evidently occaſioned by the ſudden re-entrance of the electric fire naturally belonging to his body and to the ſecond conductor, which

which had before been expelled from them, by the action of the charged prime conductor upon them, and which returns to its former place in the instant when that action or elastic pressure ceases. When the second conductor and the insulated person are placed in the densest part of the electrical atmosphere of the prime conductor, or just beyond the striking distance, the effects are still more considerable; the returning stroke being extremely severe and pungent, and appearing considerably sharper than even the main stroke itself, received directly from the prime conductor. Lord Mahon, in the application of this experiment, and of the doctrine deduced from it, observes, that persons and animals may be destroyed, and particular parts of buildings may be considerably damaged, by an electrical returning stroke, occasioned even by some very distant explosion from a thunder cloud; possibly at the distance of a mile or more. It is certainly easy to conceive (says a very ingenious anonymous writer, in his reflections on this subject) that a charged extensive thunder cloud must be productive of effects similar to those produced by the prime conductor. Like the conductor, while it continues charged, it will, by the superinduced elastic electrical pressure of its atmosphere, drive into the earth a part of the electrical fluid naturally belonging to the bodies which are within the reach of its widely extended atmosphere, and which will, therefore, become negatively electrical. This portion, too, of their electric fire will, on the explosion of the cloud at a distance, and the cessation of its action upon them, suddenly return to them, so as to produce an equilibrium, and restore them to their natural state. But the effects are not so great, nor the danger so terrible, as the noble author seems to apprehend. If the quantity of electric fluid naturally contained, *e. gr.* in the body of a man, were immense or indefinite, his lordship's estimate between the effects producible by a cloud, and those caused by a prime conductor, might be admitted; but surely an electrified cloud, how great soever may be its extent and the height of its charge, when compared with the extent and charge of a prime conductor, cannot expel from a man's body (or any other body) more than the natural quantity of electricity which it contains. On the sudden removal, therefore, of the pressure by which this natural quantity had been expelled in consequence of the explosion of the cloud into the earth, no more (at the utmost) than his whole natural stock of electricity can re-enter his body, provided he be so situated, that the returning fire of other bodies must necessarily pass through his body. But we have no reason to suppose that this quantity is so great, as that its sudden re-entrance into his body should destroy or even injure him.

In the experiment above described, the insulated person receives into his body, at the instant of the returning stroke, not only all that portion of his own natural electric fire which had been expelled from it, but likewise transmits through it, at the same instant, in consequence of his peculiar situation, all the electric fire of which the largest second conductor had been robbed, and which must necessarily repass through his body, to arrive at that conductor. To render the case somewhat parallel in natural electricity, the man's body must be so peculiarly circumstanced, supposing him to be in a house, that the electric matter which has been expelled from the house into the earth, by the pressure of an extensive thunder cloud, could not return back into the building, on the explosion of the cloud at a distance, without passing through his body: a case not likely to happen, unless the house were insulated (like the second conductor in the preceding experiment), and his body became the channel through which alone the house could have its electric matter restored to it. It appears much more probable, that the electric matter returns to the house through the same channels by which it before insensibly passed out, and with equal silence, though more suddenly. In the case of a man who is abroad, and in an open field, during the time of an explosion; as he is unconnected with other masses of matter above him, no more than the precise quantity of electric fire, which had been before expelled from his body, will suddenly return into it at the instant of a distant explosion; and that this quantity is not very large, may be inferred from many considerations. Allowing, therefore, the existence of the returning stroke, as sufficiently ascertained, and well illustrated, in a variety of circumstances, by the author's experiments, the magnitude and danger of it are not so alarming as he apprehends. Lord Mahon's Principles of Electricity, &c. 4to. 1779, p. 76—113—131. Monthly Review, vol. lxii. p. 436—442.

RETURNO HABENDO, or *Returnum averiorum*, in *Law*, a writ which lies for him who has avowed a distress made of cattle, and proved his distress to be lawfully taken; for the return of the cattle distrained unto him, which before were replevied by the party distrained, upon surety given to pursue the action.

The same writ is granted when the plaint or action is removed by *recordare* or *accedas ad curiam*, into the court of common pleas; and he whose cattle were distrained makes default, and does not prosecute his action. See REPLEVY.

RETURNUM AVERIORUM, a judicial writ, the same with *retorno habendo.*

RETURNUM *Irreplegiabile*, a judicial writ, sent out of the common pleas to the sheriff, for the final restitution or return of cattle to the owner, unjustly distrained damage feasant, and so found by the jury before justices of assize in the county, or otherwise through default of prosecution.

RETUSAVI, in *Geography*, a name formerly given to a small island of Russia, in the gulf of Finland, on which the town of Cronstadt stands, and now called the isle of Cronstadt; 20 miles W. of Petersburg. This is only remarkable for an excellent haven, strongly fortified, the chief station of the Russian fleet.

RETUSUM FOLIUM, in *Botany*, a retuse, or abrupt, leaf, terminates bluntly, with a broad shallow notch, as in *Rumex digynus*, or Mountain Sorrel. See LEAF.

RETWEYER, in *Geography*, a lake of Bavaria, in the bishopric of Bamberg; 6 miles N.E. of Vilseek.

RETZ, JOHN-FRANCIS-PAUL DE GONDI, *Cardinal de*, in *Biography*, a celebrated political character, was born at Montmirel in 1614. His father, who was general of the gallies, obliged him, against his inclination, to embrace the ecclesiastical profession. He passed through his course of study with distinction, and was made a doctor of the Sorbonne in 1643, in which year he was nominated coadjutor to the archbishop of Paris. In his conduct and character he set at defiance public opinion, and engaged in almost every species of debauchery: he fought several duels, and delighted in political intrigue. According to Voltaire, he was, at the age of twenty-three, eager in carrying on a conspiracy against the life of cardinal Richelieu. The ministry of Mazarin, however, was the period in which he most engaged as a partisan, and he engaged deeply in all the cabals which produced the petty civil war of the Fronde. He imposed upon the people by a feigned devotional seriousness in performing his prelatical functions, and affected the greatest zeal for the privileges of the clergy and the good of the public. He was among the most violent opposers of the court, and once took his seat in the parliament with a poniard in his pocket, the handle of which being seen, it was neatly observed

observed, "there is our archbishop's breviary." He boasted that he had a principal share in urging the Parisians to take up arms on the day of *barricades*. At length, however, he found that the interests of his ambition would be better served by making a secret accommodation with the court, and he was brought over by a cardinalate, to which he was nominated by the king in 1651. Like other deserters, he lost his popularity, and was able only to act a secondary part on the political stage. Continuing his cabals, Mazarin, who hated and dreaded him, procured his arrest at the Louvre, and caused him to be thrown into prison. From the dungeon he escaped, and went to Rome, where he was received with distinction as the enemy of Mazarin. He was present at the election of Alexander VII., but finding that pontiff cool to his interests, he left Italy, and passed some years in wandering through Holland, Flanders, and England. Wearied with a life of exile, he returned to France in 1661, after Mazarin's death, and made peace with his court by the renunciation of his archbishopric, to which he had succeeded at the death of his uncle, obtaining the abbacy of St. Denis by way of recompence. He had hitherto lived in great style, and had plunged himself deeply in debt, but he now resolved to live on a very limited income, till he had satisfied his creditors. This he completely effected, and lived to be in circumstances that allowed him the gratification of being liberal to his necessitous friends. In 1675 he sent back his cardinal's hat, intending to quit the world, but the pope refused to accept his resignation. His conduct in the latter part of his life obtained for him the esteem of men of worth: he died at Paris in 1679, at the age of 66. The character of cardinal de Retz has been drawn by almost all the French historians who have written since his time. By one he is described "as a person who, with the habit of a priest, displayed a disposition better suited to camps or courts; and licentious in manners and profligate in his morals, he acquired an ascendancy over the minds of the people, without condescending to throw a veil over his vices, or employing the popular pretext of religion." Another writer says, he was "daring, turbulent, false, intriguing, with designs rather romantic than great, and conducted rather with dexterity than ability: he seems to have been exactly fitted for the part which he sustained, of a political meteor in troublesome times, among a frivolous and licentious people." Voltaire, speaking of the memoirs of the cardinal, drawn up by himself, says, "they are written with an air of greatness, an impetuosity of genius, and an inequality, which are the image of his conduct. He composed them in his retreat, with the impartiality of a philosopher, but of one who had not always been a philosopher. He neither spares himself nor others." Other writings of cardinal de Retz have been published relative to the times and party.

Retz, in *Geography*, a town of Bavaria; 26 miles N.N.E. of Ratisbon.

RETZBACH, a town of the duchy of Wurzburg; 4 miles S.S.E. of Carlstadt.

RETZIA, in *Botany*, an elegant Cape shrub, so named by professor Thunberg, in the Transactions of the Academy of Lund, in honour of his friend Andrew John Retzius, member of the Stockholm Academy, and of various other learned societies, Professor of Natural History at Lund. This distinguished botanist and worthy man is best known, out of his own country, by his folio volume of *Observationes Botanicæ*; and his *Floræ Scandinaviæ Prodromus*, a systematic octavo work, in the Linnæan manner. He has, besides, published many essays and dissertations, relating to various branches of natural knowledge, both in Latin and Swedish, and is still living.—Thunb. Act. Lund. v. 1. 55. Nov. Gen. 4. Linn. Suppl. 18. Schreb. 115. Willd. Sp. Pl. v. 1. 843. Mart. Mill. Dict. v. 4. Juss. 133. Lamarck Illustr. t. 103.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Convolvuli*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, in five rather deep, lanceolate, acute, unequal segments. *Cor.* of one petal, tubular, cylindrical, villous both within and without, terminating in five ovate, obtuse, concave, erect segments, very hairy at the summit. *Stam.* Filaments five, awl-shaped, inserted into the corolla, shorter than its limb; anthers arrow-shaped, compressed. *Pist.* Germen superior, oblong; style thread-shaped, longer than the corolla; stigma in two small, linear, obtuse segments. *Peric.* Capsule oblong, acute, with two lateral furrows, two cells and two valves. *Seeds* several, minute.

Ess. Ch. Corolla of one petal, cylindrical, externally hairy. Stigma cloven. Capsule of two cells, with many small seeds.

1. R. *spicata*. "Thunb. Act. Lund. v. 1. 55. t. 1. f. 2." Linn. Suppl. 138. Willd. n. 1. (R. capensis; Thunb. Nov. Gen. 5.)—Native of high, dry, hilly situations, at the Cape of Good Hope. Gathered by Mr. Niven in Hottentot's Holland. The *stem* is shrubby, erect, from four to seven feet high, with round, knotty, hairy, leafy *branches*. *Leaves* densely imbricated, somewhat whorled, sessile, linear-lanceolate, rigid, acute, thick-edged, entire, two inches or more in length; hairy about the lower part. *Flowers* axillary, sessile, solitary, plentiful towards the ends of the branches, about as long as the leaves; villous and hoary externally; dark purple within.

The remark of Linnæus the younger, in the Supplement, respecting this genus, is very extraordinary. He says "it is no natural genus, but agrees so much with *Convolvulus*, in habit and character, as to differ in nothing except the tubular corolla, which is externally very hairy." Now in fact, its rigid shrubby habit is altogether that of a *Protea*, nor can any thing be less like a *Convolvulus*, even of the shrubby kind. The character of the *corolla* is also most distinct, being cylindrical, and wanting the five plaits, so essential to *Convolvulus*. It is true that the *Retzia* requires to be observed by some botanist conversant with natural orders, that we might have clearer ideas of its characters and affinities. The plant is a stranger in our gardens.—We have not had an opportunity of consulting the Lund Transactions, to determine whether the specific name is there *capensis* as Thunberg, or *spicata* as Linnæus, cites it. Both are highly exceptionable.

RETZSTADT, in *Geography*, a town of the duchy of Wurzburg; 5 miles S.S.E. of Carlstadt.

RETZTAT, Ober, or *Upper*, a river of Franconia, which rises near Weissemburg, passes by Oettingen, and joins the Unter Retztat, to form the Rednitz.

Retztat, *Unter*, a river of Franconia, which rises near Burg Bernheim, in the principality of Culmbach, and joins the Upper Retztat, three miles N.E. of Spalt, to form the Rednitz.

REVA, a town of Asiatic Turkey, in Natolia; 10 miles E. of Constantinople.

REUCHLIN, John, in *Biography*, a celebrated German philosopher, and assiduous contributor to the revival of learning in the 15th and 16th centuries, descended from a respectable family in Swabia, was born in the year 1454. He made a most rapid progress in school-learning, and when that was completed, he went to Paris with the young marquis of Baden, who had been his class-fellow at school. Here he pursued his studies under the most celebrated masters in Europe, and soon became well skilled in the Aristotelian philosophy. In this city, and in the diligent pursuit of learning, he remained till he was twenty years of age, when he went to Basil, where he was admitted a master in philosophy, and taught the Greek language to numerous pupils, with great reputation. Here he also prosecuted his study of the Hebrew, the elements of which he learnt while very young. At the same time, judging that the best manner of learning is by teaching, he drew up and published a grammar, a lexicon, and vocabulary, which at that period were highly esteemed, and thought to be of great use in instructing young people. Having spent four years at Basil, he went to Orleans for the purpose of studying jurisprudence, and he also taught the Greek language in that city. From this place he removed to Poictiers, where he was admitted to the degree of doctor. He next accompanied the count of Wittemberg in a tour through Italy, and was introduced at the court of Lorenzo de Medici, at Florence, and contracted an intimacy with Ficinus, Politian, Picus, and other illustrious Platonic philosophers, and was induced to embrace their opinions. In these opinions he was confirmed at Rome by the learned Hermolaus Barbarus, who, disliking the harshness of the German name Reuchlin, prevailed upon him to change it for one more musical, namely, CAPNIO, signifying, like *Reuchlin*, *smoke*, and by this he was afterwards known among foreigners. He conducted himself with so much ability and address in his tour, that he was, after his return to Germany, deputed as ambassador from the count of Wittemberg, to the emperor Frederic III. at Vienna. During his residence at this court, he made further progress in the Hebrew language, under the instructions of one of the emperor's physicians, who was a Jew; and it was contrived by the Jew, that among the presents which, according to custom, he was to receive as ambassador, should be included a beautiful and ancient manuscript Hebrew bible, as a special compliment paid to him by the emperor, on account of his eminent literary attainments. Frederic dying in 1493, Reuchlin returned to the court of Wirtemberg, and was appointed to be the count's deputy to the diet of Worms, in which his prince was elevated to the ducal dignity. Scarcely had he enjoyed that honour three months, when he died, leaving his dominions to his nephew Ulric. The power of this prince was contested by another nephew, who assumed the title of Eberhard II., and who carried the point. One of the first acts of this prince was to banish Reuchlin for his attachment to the interests of prince Ulric. He now retired to Worms, and wrote "An Epitome of the History of the four Empires," for the use of the prince Palatine. He also wrote at this time two Latin comedies, abounding with wit and satire, which were afterwards published. In 1498, the elector Palatine, having been involved in a dispute with pope Alexander VI., fixed upon Reuchlin as the person best qualified to defend his cause, and sent him for that purpose to Rome in the capacity of his ambassador. On this occasion he pronounced an able and eloquent oration before the pope and cardinals, concerning the rights of princes, and the privileges of the churches in Germany, which was printed by Aldus. Before he returned to Germany, a revolution had taken place at Wirtemberg, the usurper having been expelled, and Ulric reinstated in his rights. Upon this change, Reuchlin was recalled to the ducal court by the guardians whom the emperor had appointed for Ulric, and very soon after he was nominated to the dignity of one of the triumvirs of the league of Swabia for the emperor and the electors. He was next sent ambassador to the emperor Maximilian; and upon his return, finding the plague raging in Swabia, he retired to Stutgard, where he was hospitably received into a monastery of the Dominicans, and at their request, he drew up a work on the art of preaching. Towards the close of his life he encountered much trouble and danger from the resentment of the monks and other bigots of Cologne, occasioned by his opposition to their enthusiastic rage for the destruction of all Jewish books excepting the bible. It is not necessary to enter at large into the nature of this controversy, it will be sufficient to observe, that Reuchlin found himself compelled to carry his cause to Rome, for the definitive sentence of the papal see. Here he had many friends, and his agent carried with him strong recommendations from princes, prelates, and men of the greatest eminence in the learned world. These recommendations had great weight in the court of Leo X., and Reuchlin was honourably acquitted of the heresy with which he was charged, to the great mortification of his bigotted and malignant enemies. Amidst the troubles which he met with he prosecuted his studies with unabated ardour, and published some very learned and profound works. Although, as we have seen, he triumphed over his enemies at the court of Rome, they did not cease to trouble him, by the invention of groundless calumnies, and the most bitter invectives; so that, notwithstanding his great talents, he was scarcely able, by teaching the Greek and Hebrew languages, to keep himself from want. He died in the year 1521, at the age of sixty-eight. His principal works, independently of those already noticed, are, "The Life of Constantine the Great," written by Eusebius: a treatise "De Verbo Mirifico," in the form of a dialogue between a philosopher, a Jew, and a Christian; and another treatise "De Arte Cabbalistica." For his great and successful attempts towards the revival of learning, his name is deserving of being remembered with gratitude by posterity. His collection of "Letters from illustrious Men," of which an edition was published at Zurich in 1558, is said to be full of valuable information concerning the literary history of his time. Dupin speaks of him as one of the most learned men of that age; and he adds, that notwithstanding his attachment to his peculiar studies, he had a wonderful genius for the belles lettres; was intimately conversant with the Grecian philosophers and orators; was a perfect master of the Greek language, and spoke Latin with an inimitable purity and elegance; and that he was the only person of whom Germany at that time could boast, who deserved to be regarded as a competitor for fame with all the learned men in Italy, who was their equal in the delicacy of his style, while he greatly excelled them in erudition. Moreri. Dupin. Enfield's Hist. Phil. vol. ii.

REUDEN, in *Geography*, a town of Saxony; 5 miles N.W. of Bitterfeld.

REUDZEL, a river of European Turkey, which runs into the Reut, 18 miles W. of Florefzti, in Moldavia.

REVE, or GREVE, in *Ancient Customs*, the bailiff of a franchise, or manor, thus called; especially in the western parts.

Hence, shire-reve, sheriff, port-greve, church-reve, &c. See SHERIFF, PORT-GREVE, &c.

REVE, *Reva*, is also used for a duty or imposition on merchandizes imported.

M. Du-Cange derives the word from the Latin *roga*, of *rogare, to ask*; the word formerly signifying a tribute anciently granted princes at their request, as a free gift.

REVEALED RELIGION. See RELIGION and REVELATION.

REVEALED *Theology*. See THEOLOGY.

REVEILLE, formed of the verb *reveiller*, *to awake*, a beat of drum in the morning, intended to give notice that it is is day-break; and that the soldiers are to arise, and the sentinels forbear challenging.

REVEL, in *Geography*, a town of France, and principal place of a district, in the department of the Upper Garonne; 21 miles N.W. of Carcassone. N. lat. 43° 28'. E. long. 2° 5'.—Also, a town of France, in the department of the Isere; 15 miles S.E. of Vienne.—Also, a sea-port town of Russia, on the Baltic, and capital of a province; the see of a Lutheran bishop, suffragan to the archbishop of Riga. Although this place be not large, it is opulent and well fortified; and has considerable trade. The town and castle were founded, in 1218, by Waldemar II., king of Denmark, on the scite of the convent of St. Michael, founded by his ancestors, and in 1320 included within its walls. Revel, and also the whole duchy of Esthonia, received most of its privileges from the Danish kings; and the arms of Denmark, with inscriptions in the Danish language, are still seen in the churches and other public offices. The houses are generally built of brick, and the streets are somewhat regular. The only congregations here, besides those of the Russian church, are Lutheran. The tolls, belonging partly to the magistracy, and partly to the crown, are considerable. This town has its own arsenal, and maintains a number of matrosses, and a company of soldiers. Revel formerly held a distinguished rank among the Hanse towns, and it is still a staple-town, with a flourishing trade. Its harbour is spacious and convenient, and usually accommodates a part of the Russian fleet. It is surrounded with high walls, strengthened with bastions, and a deep ditch; and it is also fortified with a castle, seated on a rock, and ornamented with several towers. Without the walls the citizens have pleasant gardens. This city was erected into a bishopric by Waldemar II. It was totally destroyed by fire in 1433. In 1710 it was surrendered to Peter the Great, who confirmed its ancient privileges, and restored others of which it had been deprived by the crown of Sweden; 144 miles N. of Riga. N. lat. 59° 20'. E. long. 24° 34'.

Revel's *Island*, a small island near the coast of Virginia. N. lat. 37° 35'. E. long. 75° 43'.

REVE-LAND, the land which in Domesday is said to have been *thane-land*, and afterwards converted into *reve-land*, seems to be such land as, being reverted to the king after the death of the thane, who had it for life, was not since granted out to any by the king, but rested in charge upon the account of the *reve*, or bailiff of the manor. Spelm. Feuds, cap. 24.

REVELATION, Revelatio, formed from *revelo*, of *re*, and *velum*, *q. d. to unveil*, the act of revealing, or making a thing public, which before was a secret, or unknown.

The revelation of a confession, made by the confessor, is adjudged, in the Romish church, to deserve the most exemplary punishment.

Revelation is used, by way of eminence, for the discoveries made by God to his prophets, &c. and by them to the world.

Revelation is more particularly used for the discovery which God has made to the world, by the mouths of his prophets, of certain points of faith and duty, which they could not learn from natural reason.

Religion is divided into natural religion and revelation, or revealed religion. See Religion.

By revealed religion, as distinguished from that which is usually called natural, we are to understand that knowledge of religion which was originally communicated in an extraordinary and supernatural way. A revelation of this kind must either be by an immediate infallible inspiration, or illumination of every particular person, for informing and directing him with regard to the knowledge and practice of religion; or by God's making an extraordinary discovery of himself and of his will to some person or persons, who should be commissioned to communicate it to others in his name. In the former case it could not be properly called extraordinary revelation; for if it were an universal infallible light, imparted to every single person in every nation and every age, from the beginning of the world, it would be as common and familiar to every one as the common light of reason, and by being universal would cease to be extraordinary. Whereas, if there be such a thing as revealed religion, or if it hath pleased God to make discoveries of his will to mankind with respect to religious truth and duty, in a way of extraordinary revelation, the most natural mode of doing it, and that which is best accommodated to the present state of mankind, seems to be, that the revelation should be communicated to some person or persons, to be by them communicated to others in his name; at the same time furnishing them with sufficient proofs and credentials, to shew that they were indeed sent and inspired by him, and that the doctrines and laws which are the matter of such revelation, and which they are authorised to publish to the world in his name, were really and originally communicated by revelation from him. This method admits of sufficient proof being given to satisfy well-disposed minds, and of provision being made for instructing men, unless it be their own fault, in the knowledge of religion, and engaging them to the practice of the duties which it requires; and, at the same time, there is room for the exercise of reason in examining the nature of the evidence, and the trial of men's sincerity and diligence, of their impartial love of truth, and their openness to receive it.

Several questions present themselves to our consideration, with regard to that kind of revelation that has been now stated. The *first* relates to the possibility of it; the *second*, to its usefulness and expediency, and even the necessity of it in the present state of mankind; the *third* relates to the proofs and evidences, by which it may be shewn, that such a revelation hath been actually given.

As to the *first* question, the affirmative cannot reasonably be doubted by any one, much less denied, who believes a God and a Providence. Can it be supposed, that the Author of our being, and of our faculties, hath it not in his power to communicate ideas to our minds, for instructing and informing us in what it nearly concerns us to know?

It is acknowledged, even by lord Bolingbroke, a writer of distinguished rank among the opposers of revelation (Works, vol. ii. p. 468, ed. 4to.), "that an extraordinary action of God upon the human mind, which the word 'inspiration' is now used to denote, is not more inconceivable than the ordinary action of mind upon body, or body on mind;" and "that it is impertinent to deny the existence of any phenomenon, merely because we cannot account for it." Moreover, as God can, if he thinks proper, communicate his will to mankind, he can also do it in such a manner, as to give to those to whom it is originally and immediately made, a full and certain assurance of its being a true divine revelation. Besides, God can commission those to whom he has made an extraordinary revelation of his will, to communicate to others what they have received from him; and can furnish them with such credentials of their divine mission as are sufficient to prove that he sent them, and that the doctrines and laws which they deliver in his name were indeed received from God. The omnipotent Author of nature, and Lord of the universe, can undoubtedly, if he thinks fit, enable such persons to perform the most wonderful works in his name, as a proof that he fent them; works of fuch a nature, and fo circumftanced, as manifeftly to tranfcend all human power, and bear the evident marks of a divine interpofition. (See MIRACLE.) He can alfo endue them with fupernatural gifts, and enable them to deliver exprefs predictions of future contingent events, which no human fagacity could forefee, and which yet fhall be accomplifhed in the proper feafon. (See PROPHECY.) It fhould alfo be further obferved upon this fubject, that not only they who live in the age when the revelation was firft publifhed to the world may have fuch proofs of it as may be fufficient to convince them of its divine authority and original, but that it may be tranfmitted with fuch evidence to thofe who live in fucceeding ages, as may lay them under an obligation to receive and fubmit to it as a revelation from God. Although oral tradition is not a very fure conveyance, yet it is undeniable, that writings may be tranfmitted with fuch a degree of evidence as to leave no room for reafonable doubt. This is the moft fimple and natural way of propagating the knowledge of revelation to fucceeding ages. Such is the fact with regard to the revelation contained in the holy fcriptures: nor is it difficult to prove, that we have greater evidence of the fafe tranfmiffion of thefe facred writings, without any general and material corruption and alteration, than we have concerning other books, the genuinenefs of which is univerfally acknowledged. To this kind of argument it can only be objected, that moral evidence is uncertain, and hiftorical human teftimony fallible; but to the objection the reply is obvious, that this kind of evidence may be, and frequently is, fo circumftanced, that the man would fcarcely be thought in his fenfes who fhould ferioufly deny or doubt of it. It is by moral evidence, and the teftimony of fallible men, capable of deceiving and of being deceived, that a man who has never been at Paris or Rome knows that there are fuch cities, and yet he can no more reafonably doubt of it, than if he had feen them with his own eyes. It is by moral evidence, that we have all our laws and records, and the affurance of any paft facts. And yet is there any man of fenfe, who does not as certainly believe many facts which were done in former ages, as he believes any event that has happened of late years, and within his own memory? It is by this kind of evidence of teftimony that we are neceffarily guided and determined in many cafes of great importance: and why fhould it be thought abfurd to fuppofe, that it fhould be fo ordered by the Author of our frame and the great Ruler of the world, that our knowledge of fome important matters relating to religion fhould be obtained by this mode of conveyance? He that receives divine revelation upon this kind of evidence acts a wife and good part, becoming a reafonable being and a moral agent.

Having fhewn that a revelation from God is poffible, the *fecond* fubject of confideration is the great ufefulnefs and advantage of divine revelation, and the neceffity of it in the prefent ftate of mankind, for fupporting and promoting the interefts of religion and virtue in the world. Such a revelation may be of great ufe even with regard to thofe truths and principles which lie at the foundation of all religion; fuch are the truths which relate to the excellent and unparallelled nature, the perfections and attributes of the one fupreme God. (See GOD.) A divine revelation may alfo be very ufeful in eftablifhing the belief of the providence of God; and further, in communicating inftruction even to thofe, who allow that fome kind of religious worfhip and homage fhould be rendered to God by his reafonable creatures. What kind of worfhip will be moft acceptable to the Supreme Being, and what rites are moft proper to be ufed in his fervice, are queftions which unaffifted reafon cannot pofitively and with certainty determine. The doctrine of the immortality of the foul, and of a future ftate of retribution, is unqueftionably of very great importance to mankind; and the natural and moral arguments to prove it have certainly great weight; but they are affailed by difficulties and objections which weaken the evidence, and may occafion fufpicion and doubt, if natural reafon be our only guide and umpire. Accordingly fome of the moft eminent ancient philofophers either denied this doctrine, or expreffed themfelves doubtfully and waveringly concerning it. If then God himfelf fhould, by a well-attefted revelation, affure us, that death fhall not put an utter end to our being; that the prefent life is only the firft ftage of our exiftence; that we fhall be raifed again from the dead; and that God will call all men to an account, and reward or punifh them in a future ftate according to their behaviour in this; and fhould alfo fignify to us the nature of thofe rewards and punifhments, and the qualifications of the perfons on whom they fhall be conferred or inflicted: this muft needs be of high advantage, and tend to give us fatisfaction in a point of confiderable importance, for encouraging men in the practice of virtue, and delivering them from vice and wickednefs. Moreover, we are led by the light of nature and reafon to entertain fome hope, that God will fhew mercy to finners upon their repentance and amendment; but how far this mercy fhall extend, whether he will pardon fins of every kind, even the moft heinous, frequently repeated, and long perfifted in, merely upon repentance and amendment; and whether his pardon in this cafe will be only a mitigation or remiffion of the threatened penalty, without a full reftitution to grace and favour, and how far he will reward an obedience attended with failures and defects:—thefe things might create anxious doubts and perplexities to ferious and thoughtful minds. Efpecially when it is further confidered, that reafon leads us to regard God as juft as well as merciful, a wife and righteous governor, who will therefore exercife his pardoning mercy in fuch a way as feemeth moft fit to his rectoral wifdom, and will beft anfwer the ends of moral government; and of this fuch fhort-fighted creatures as we are cannot pretend to be competent judges. A revelation from God fatisfying mankind, and efpecially anxious penitents, with regard to thefe interefting queftions, and affuring them by exprefs promife, as well as by its reprefentations of the placability of God, and of the provifion which he has made for the pardon of repenting tranfgreffors in perfect confiftence with all the attributes of his nature and laws of his government, muft be a very great benefit to the world. The affiftance promifed and certified by revelation, to thofe who ufe their own earneft endeavours in the performance of their duty, muft further evince its importance and utility. Befides, the benefits of a divine revelation further extend to thofe laws and duties which we owe to God, our neighbours, and ourfelves, and which are comprehended under the clafs of moral obligations. But though revelation is thus eminently ufeful, and even neceffary, it is not defigned to fuperfede the ufe of our own reafon, or to render the exercife of it needlefs, but to guide, improve, and perfect it. Revelation, fo far from difcarding or weakening any argument that can be juftly brought from reafon, in proof of any truths relating to religion or morality, adds to them the atteftation of a divine authority or teftimony, which is of great weight. This both gives us a farther degree of certainty with regard to thofe things which are in fome degree difcoverable by the light of reafon, and alfo furnifhes us with a fufficient ground of affent, with refpect to thofe things which mere unaffifted reafon, if left to itfelf, would not have difcovered, and which yet it may be of ufe for us to know.

By the common consent of mankind, a competent authority is, in many cases, a good and proper medium to assure us of the truth of things; and to believe upon the credit of such an authority and testimony, is so far from being a renunciation of our reason, as some have pretended, that, on the contrary, it is what reason and good sense require; and to decline it would be to act an absurd and unreasonable part. Admitting that a supposed revelation from God is established upon sufficient evidence, we are bound to receive what is revealed upon the authority of the revealer; insomuch that it would be a contradiction to believe it to be a revelation from God, and yet refuse our assent to it: since it is a most unquestionable principle, that, as God is incapable of deceiving or of being deceived, whatsoever he hath revealed must be true.

This leads us to the *third* subject of inquiry proposed in reference to divine revelation, *viz.* what are the proofs and evidences by which it may be known that such a revelation has been actually communicated to mankind, and that the revelation which we have in our possession is entitled to this character. We may observe in general, that it has been the sense of mankind in all ages and nations, that God hath made a revelation of his will to man; and this prevalent opinion has been probably derived from a tradition of some extraordinary revelation, or revelations, communicated in the earliest times to the first ancestors of the human race, from whom it has been transmitted to their descendants; though, in process of time, it has been in a great measure corrupted and lost. Or at least we may hence conclude, that men have generally thought that a revelation from God to man was both possible and probable; and that this was agreeable to the ideas they had formed of the wisdom and goodness of God, and of his concern for mankind. It would lead us far beyond the limits of this article, particularly to state the proofs that have been alleged for the divine authority of the Jewish and Christian revelation; both of which refer to and confirm the original revelation made to mankind from the beginning. But this is the less necessary, as the subject is discussed in various parts of the Cyclopædia. See BIBLE, CANON, CHRISTIAN *Religion*, RELIGION, RESURRECTION *of Christ*, SCRIPTURE, TESTAMENT, &c.

The Christian revelation is that made by Christ, and his apostles, in the New Testament. The Jewish revelation is that made by Moses and the prophets, in the Old Testament. See CHRISTIAN *Religion*, and JUDAISM.

A late author observes, somewhat invidiously, that it is the common method of all new revelations, to be built on precedent ones. Thus, the mission of Moses to the Israelites supposes a former revelation to Abraham, &c. The mission of Christ supposes that of Moses; and the pretended mission of Mahomet supposes the mission of Christ. The mission of Zoroaster to the Persians supposes the religion of the Magi, &c.

The general foundation of all revelation is this, that God is pleased man should know something relating to himself, his own nature, dispensation, &c. which the natural faculties with which he was pleased to create him could not attain to; and that he requires some duty or service at our hands, more than what necessarily follows from the relation we are under to him as our creator, preserver, &c.

This is also urged by deists, to the discredit of all particular revelations, as derogating from the perfections of God; such supplementary informations and instructions arguing, according to them, a prior deficiency in the established economy of nature, of which he is the author. But many able answers have been given to such cavils.

Particular or occasional revelations have their particular geniuses, characteristics, and designs. That made by Moses and the prophets chiefly related to the nation of the Jews, considered as the descendants of Abraham: its design seems to have been to rescue that people from their slavery; to settle them in a new plantation; to give them a set of laws; to new-form their manners; to support them under difficulties and dangers of their enemies, from an opinion of their being under the immediate direction and appointment of God; to keep them from intermixing again with their neighbours, from an opinion of their being a chosen people, and of a Messiah to be born among them; and thus to preserve and transmit the knowledge of the unity of God, in opposition to idolatry and polytheism, and the hope of the Messiah, till the period of his appearance arrived. To some or other of these ends do all the Old Testament prophecies seem to tend.

The Christian revelation is founded on a part of the Jewish. The Messiah promised in the one is revealed in the other.

All the rest of the Jewish revelation, which related peculiarly to the Jewish people, is here set aside; and only that part of it in which the world in general was interested, and that relating to the advent, offices, and character of the Messiah, are retained.

Indeed, it must be owned, the Jews ever looked on this to be as peculiar to themselves as any of the rest; the Messiah was promised to them; he was to be their deliverer, their restorer, &c. and under this character he actually appeared. But, upon taking place of this new revelation, a new scene was opened, different from what many of them apprehended, because they misinterpreted the prophecies relating to the Messiah. The ceremonial part of their institution, local and temporary in its establishment and use, was abolished; and the Messiah appeared, not, as they erroneously imagined, to be the restorer of their civil sovereignty and liberties, which were now fallen into the hands of the Romans; but to restore and re-establish mankind in general, who had lost their original righteousness, and were become slaves of sin; to preach repentance and remission; and at last to suffer death, that all who believed in him might not die, but have everlasting life.

Such are the tenor and design of the Christian revelation, which, in the event, was so far from being what it had been apprehended to be by the people to whom it was first promised, that it proved the very reverse; and, instead of re-establishing and confirming the other branches of their revelation, it superseded, and set them all aside. The pale was now broken down, and the being of the seed of Abraham ceased to be a privilege, all the world being invited on the same terms with the Jews.

The consequence was, that the Jews, denying this to be the Messiah that had been promised to them, because their pride and prejudice prevented their discerning the accomplishment of their ancient prophecies in him, were generally excluded from the privileges of that mission, which they had vainly supposed to be not only primarily but wholly intended for themselves; and had their ruin completed from the very means whence they expected their redemption: because they expected a redemption, different in its nature from that which their own prophecies, fairly interpreted, proposed.

REVELLO, in *Geography*, a town of France, in the department of the Stura, near the Po, seated on the summit of a very high mountain, fortified both by nature and art. Having formerly served as a place of refuge for the marquises of Saluzzo, and withstood many attacks from their enemies, it was taken by the French; and in 1588 it surrendered to Charles Emanuel I., duke of Savoy. It contains one parochial church, and three other churches, a castle,

castle, a palace, and a convent of Dominicans; 3 miles N.W. of Saluzzo.

REVELS, formed from the French *reveiller, to awake*, as alluding to the night season, when they were chiefly held; entertainments of dancing, masking, gaming, acting comedies, farces, &c. anciently very frequent in inns of courts, at certain seasons, and in noblemen's houses, &c. but now much disused.

The officer who has the direction or ordering of the revels at court, is called the *master of the revels*.

REVELSKOI, in *Geography*, a province of Russia, so called from *Revel* the capital, bounded on the N. and W. by the Baltic, on the E. by the government of Petersburg, and on the S. by the government of Riga; about 144 miles in length, and from 16 to 60 in breadth; formerly the duchy of Esthonia. N. lat. 58° 20′ to 59° 30′. E. long. 23° to 28′. See ESTHONIA and REVEL.

REVENGE, in *Ethics*, is an insatiable desire to sacrifice every consideration of pity and humanity to the principle of vindictive justice. It renders the demands of that terrific giant paramount to every other claim. It is a propensity to retaliate evil, too fervent to be cooled by time, too deep and inveterate to be obliterated by concessions and intreaties. It anticipates joy in the contemplation of sighs and groans, and the only moment of transport is the instant of inflicting misery. This disposition approaches very near to permanent malevolence of the most despicable character. The abstract idea of justice, however, forms a partition between them; for to this, malevolence has no rightful claim. But its more honourable distinction consists in that repentance, which humanity excites in the mind that is not totally obdurate, after the gratification of this dreadful passion.

Anger long indulged to excess is apt to produce revenge. See ANGER.

REVENUE, the yearly rent or profits arising to a man from his lands, possessions, &c.

The word is French, formed from *revenir, to return*. Whence revenue is sometimes also used in ancient authors for a return; as the revenue of Easter.

The revenues of the English clergy were first fixed by king Ethelwulph, anno 853, who granted them for ever the tithe of all goods, and the tenth part of all the lands of England, free from all secular service, taxes, impositions, &c. Though Rapin observes, that tithes were settled on the clergy by the laws of Ina and Offa. But these laws were probably not observed, or perhaps Ethelwulph extended the law of tithes all over England. See TITHE.

The certain revenues of the king of England were anciently greater than those of any king in Europe; and till the time of the civil wars they enjoyed, in domains and fee-farm rents, almost enough to discharge all the ordinary expences of the crown, without any tax or imposition on the subject.

The revenue which the British constitution hath vested in the royal person, in order to support his dignity, and maintain his power, is either *ordinary* or *extraordinary*.

The king's *ordinary* revenue is such as hath either subsisted time out of mind in the crown, though, by reason of royal grants, the king be not at present in the actual possession of the whole of it; or else has been granted by parliament, by way of purchase or exchange for such of the king's inherent hereditary revenues, as were found inconvenient to the subject. Of the king's ordinary revenues there are four, which are of an ecclesiastical kind. Such are, 1. The custody of the temporalities of bishops, or all the lay revenues, lands, and tenements, (in which is included his barony,) which belong to an archbishop's or bishop's see, and which, upon the vacancy of the bishopric, revert immediately to the king, as his right, during the vacancy. This branch of the royal revenue was formerly very considerable, but is now, by customary indulgence, reduced almost to nothing; for, at present, as soon as the new bishop is consecrated and confirmed, he usually receives the restitution of his temporalities, entire and untouched, from the king; and then, but not sooner, he has a fee-simple in his bishopric, and may maintain an action for the profits. (Co. Litt. 67. 341.) 2. A corody out of every bishopric, or a right of sending one of his chaplains to be maintained by the bishop, or to have a pension allowed him till the bishop promotes him to a benefice (F. N. B. 230.); which is now fallen into total disuse; though sir Matthew Hale says, that it is due of common right, and that no prescription will discharge it. 3. The tithes arising in extra-parochial places, which are held, indeed, under an implied trust, that the king will distribute them for the good of the clergy in general. (2 Inst. 647.) 4. The first-fruits and tenths of all spiritual preferments in the kingdom. See FIRST-*Fruits* and TENTHS.

The following branches of the king's ordinary revenue are of a lay or temporal nature. 5. The first of these consists in the rents and profits of the demesne lands of the crown, which are either the share reserved to the crown at the original distribution of landed property, or such as came to it afterwards by forfeitures or other means, and were formerly very extensive, but are now contracted within a very narrow compass, having been almost entirely granted away to private subjects. 6. The advantages which used to arise to the king from the profits of his military tenures, to which most lands in the kingdom were subject, till they were in a great measure abolished by the statute 12 Car. II. cap. 24. to which may be also referred the profitable prerogative of purveyance and pre-emption; which branches of the royal revenue and power were resigned entirely by king Charles at his Restoration; in recompence for which, the parliament settled on him, his heirs and successors for ever, the hereditary excise of fifteen pence *per* barrel on all beer and ale sold in the kingdom, and a proportionable sum for certain other liquors; so that this hereditary excise forms the sixth branch of his majesty's ordinary revenue. 7. The rents payable to the crown by such persons as are licensed to sell wine by retail throughout England, except in a few privileged places, first settled on the crown by the statute 12 Car. II. cap. 25. but abolished by the statute 30 Geo. II. cap. 19. when an annual sum of upwards of 7000*l. per annum*, issuing out of the new stamp duties imposed on wine licences, was settled on the crown in its stead. 8. The profits arising from the king's forests, consisting principally in amercements or fines levied for offences against the forest-laws, for levying which, few, if any, courts have been held since 1632, 8 Car. I. 9. The profits arising from the king's ordinary courts of justice; consisting not only in fines imposed upon offenders, forfeitures of recognizances, and amercements levied upon defaulters, but also in certain fees due to the crown in a variety of legal matters; as for setting the great seal to charters, original writs, and other forensic proceedings, and for permitting fines to be levied of lands in order to bar entails, or otherwise to insure their title. These, in process of time, have been almost all granted to private persons, or else appropriated to certain particular uses. All future grants of these, by 1 Ann. stat. 2. cap. 7. are to endure for no longer time than the prince's life who grants them. 10. The right to royal fish. 11. The revenue arising from shipwrecks, which is is frequently granted out to lords of manors, as a royal franchise. (See WRECK.) 12. The right to mines of silver and gold. (See MINE.) 13. The revenue of treasure-trove. 14. Waifs. 15. Estrays, which the law gives to the king as the general owner and lord paramount of the soil; though they now most commonly belong to the lord of the manor, by special grant from the crown. 16. Forfeitures of lands and goods for offences. (See CONFISCATE and DEODAND.) These are for the most part granted out to the lords of manors, or other liberties. 17. The revenue arising from the escheats of lands, reverting, upon the default of heirs to succeed to the inheritance, to the king, who is esteemed, in the eye of the law, the original proprietor of all the lands in the kingdom. 18. The last branch of the king's ordinary revenue consists in the custody of idiots.

Such is the king's ordinary revenue, or the proper patrimony of the crown, which was formerly very large, and capable of being increased to a magnitude truly formidable: but, fortunately for the liberty of the subject, this hereditary landed revenue is now sunk almost to nothing; and the casual profits, arising from the other branches of the *census regalis,* are likewise almost all of them alienated from the crown. In order to supply the deficiencies of which, we are now obliged to have recourse to new methods of raising money, unknown to our early ancestors; which methods constitute the king's *extraordinary* revenue. See TAX, FUND, and NATIONAL *Debt*.

We shall here observe, that the aggregate fund stood mortgaged by parliament to raise an annual sum for the maintenance of the king's household, and the civil list. For this purpose, in the late reigns, the produce of certain branches of the excise and customs, the post-office, the duty on wine licences, the revenue of the remaining crown lands, the profits arising from courts of justice, (which articles include all the hereditary revenues of the crown,) and also a clear annuity of 120,000*l.* in money, were settled on the king for life, for the support of his majesty's household, and the honour and dignity of the crown. And, as the amount of these several branches was uncertain, (though in the last reign they were computed to have sometimes raised almost a million,) if they did not arise annually to 800,000*l.*, the parliament engaged to make up the deficiency. But his present majesty, soon after his accession, having accepted the limited sum of 800,000*l. per annum* for the support of his civil list, (charged also with three life-annuities, to the princess of Wales, the duke of Cumberland, and the princess Amelia, to the amount of 77,000*l.*) the said hereditary and other revenues were made a part of the aggregate fund, which was charged with the payment of the whole annuity to the crown of 800,000*l. per annum*. The expences formerly defrayed by the civil list were those that in any shape relate to civil government: as the expences of the household; all salaries to officers of state, to the judges, and each of the king's servants; the appointments to foreign ambassadors; the maintenance of the queen and royal family; the king's private expences, or privy purse; and other very numerous outgoings, as secret service money, pensions, and other bounties; which sometimes have so far exceeded the revenues appointed for that purpose, that application has been made to parliament to discharge the debts contracted on the civil list; as particularly in 1724, when one million was granted for that purpose by the statute 11 Geo. I. cap. 17; and in 1769 and 1777, when half a million and 600,000*l.* were appropriated to the like use, by the statutes 9 Geo. III. cap. 34. and 17 Geo. III. c. 47. Many of these expences are now charged on the consolidated fund, and the civil list comprehends the support of his majesty's household.

The civil list is, indeed, properly the whole of the king's revenue in his own distinct capacity; the rest being rather the revenue of the public, or its creditors, though collected and distributed again in the name and by the officers of the crown.

The whole revenue of queen Elizabeth did not amount to more than 600,000*l.* a-year; that of king Charles I. was 800,000*l.*; and the revenue voted for king Charles II. was 1,200,000*l.*; but under these sums were included all kinds of public expence. The same revenue, subject to the same charges, was settled on king James II. (Stat. 1 Jac. II. c. 1.) But by the increase of trade, and better management, it amounted on an average to a million and a half *per annum*, (beside other additional customs, granted by parliament, (ibid. c. 3. and 4.) which produced an annual revenue of 400,000*l.*), out of which his fleet and army were maintained at the yearly expence of 1,100,000*l.* At this time the revenues of the king of France were computed at seven millions sterling; and those of the states of Holland at three millions. After the Revolution, when the parliament took into its own hands the annual support of the forces, both maritime and military, a civil list revenue was settled on the new king and queen, amounting, with the hereditary duties, to 700,000*l. per annum;* and the same was continued to queen Anne and king George I. That of king George II. was nominally augmented to 800,000*l.* (stat. 1 Geo. II. c. 1.); and in fact was considerably more. But that of his present majesty was avowedly increased to the limited sum of 900,000*l.* The clear yearly sum of 100,000*l.*, to commence from the fifth of January 1777, over and above the sum of 800,000*l.* before granted, was granted to his majesty out of the aggregate fund by stat. 17 Geo. III., but is now chargeable on the consolidated fund. Blackst. Com. vol. i. chap. viii. See FUND, and the sequel of this article.

The following particulars, relating to the revenue, are extracted from the Report presented to the house of commons, ending 5th January 1814.

An

REVENUE.

An Account of the Ordinary Revenues and Extraordinary Refources conftituting the Public Income of Great Britain, for the Year ending the 5th of January 1814.

REVENUE, *Auditors of the*. See AUDITOR.

REVENUE, *Court of*. See COURT *of Exchequer*.

REVENUE, *Officers of*, are excluded from voting in elections for members of parliament by 22 Geo. III.

REVENUE, *Revenu*, in *Hunting*, a flefhy mafs or lump, formed chiefly of a clufter of whitifh worms on the heads of deer, and fuppofed to occafion them to caft their horns, by thofe worms gnawing the roots of them.

The revenue diftilled, is faid to help women in travail.

REVENUE is alfo ufed for a new tail of a partridge, growing out after the lofs of a former. The revenue is meafured by fingers; thus they fay, a partridge of two, three, and four fingers revenue.

REVERA, in *Geography*, a fmall ifland in the Adriatic, near the coaft of Iftria. N. lat. 45° 15′. E. long. 13°.

REVERBERATION, REVERBERATIO, formed from *re*, and *verbero*, q. d. *I beat again*, in *Phyfics*, the act of a body repelling or reflecting another, after impinging on it. In the glafs-men's furnace, the flame reverberates or bends back again to burn the matter on all fides. Echoes are occafioned by the reverberation of founds from arched obftacles.

Reverberation and *refilition* refer to the fame action; only the one to the agent, the other to the patient. A polifhed body reverberates the rays all around; the refilition of the rays does not arife from their ftriking againft the folid parts of bodies. See REFLECTION.

REVERBERATION, in *Chemiftry*, denotes a kind of circulation of the flame, by means of a reverberatory; or the return of the flame from the top of the furnace back to the bottom, chiefly ufed in calcination.

Reverberation is of two kinds. The firft with a *clofe fire*; that is, in a reverberatory furnace, where the flame has no vent at top; being covered with a dome, or capital, which repels its action back on the matter, or the veffel that contains it, with increafed vehemence.

After this manner are refining, the diftillation of acid fpirits, &c. performed.

Reverberation with an *open fire*, is that performed in a furnace, or reverberatory, whofe regifters are all open; ufed in calcination, &c.

REVERBERATORY, or REVERBERATING *Furnace*, is a chemical furnace built clofe all round, and covered at the top with a capital of brick or tiles, fo as not to give any vent to the heat or flame, but to determine it to reverberate or turn back from the brick-work with new force, upon the matters placed at bottom.

When the fire has no vent or paffage at top, it is a *whole* reverberatory; when the middle of the capital is open, and only the fides clofe, fo that there is only a half circulation of the flame, it is called a *half* reverberatory.

The reverberating furnace is chiefly ufed in the fufion and calcination of metals and minerals, and on other occafions, where the moft intenfe heat is required, as in affaying, &c. Whence it is alfo called the *melting-furnace*, and *affaying furnace*. See *Reverberating* FURNACE.

REVERENCE, in *Ethics*, is the veneration, or high degree of refpect, which is paid to fuperior fanctity, intermixed with a certain degree of awe. It is the high refpect paid to the facred character of its object, attended with a confcious inferiority in moral worth.

REVEREND, REVERENDUS, a title of refpect given to ecclefiaftics.

The religious abroad are called reverend fathers; and abbeffes, prioreffes, &c. are called reverend mothers.

With us, bishops are *right reverend;* and archbishops *most reverend.* In France, their bishops, archbishops, and abbots, are all alike *reverendissimes, most reverend.*

REVERIE, a term purely French, frequently used of late in English, to signify a delirium, raving, or distraction. It is an ill sign in fevers when the patient falls into a reverie.

Hence also reverie comes to be used for any ridiculous, extravagant imagination, action, or proposition, a chimera or vision. Thus we say, authors obtrude abundance of their reveries upon us for solid truths.

But the most ordinary use of the word reverie, among English writers, is for a deep, disorderly musing or meditation, equivalent to what we popularly call a *brown study.* Thus, a little distraction I would allow; but for that continued series of reveries some people are guilty of who are ever absent from the place where you see them, and are never present any where, it is inexcusable.

REVERO, in *Geography,* a town of Italy, in the department of the Mincio, on the S. side of the Po, opposite to Ostiglio.

REVERS, Battery de. See Battery.

REVERSAL, in *Law.* See Reverse.

REVERSATA Arma. See Arma.

REVERSE, in the *Military Art,* signifies on the back, or behind. Thus we say, a reverse view, a reverse commanding ground, a reverse battery, &c.

Reverse, formed of *re, again,* and *versus, turned,* in *Law,* &c. To reverse, signifies to undo, repeal, or make void.

A judgment may be reversed or voided for matters foreign to or *debôrs* the record, that is, not apparent upon the face of it, by writ of error, and by act of parliament. The effect of falsifying or reversing an outlawry is, that the party shall be in the same plight as if he had appeared upon the capias; and if it be before plea pleaded, he shall be put to plead to the indictment; if after conviction, he shall receive the sentence of the law; for all the other proceedings, except only the process of outlawry for his non-appearance, remain good and effectual as before. But when judgment, pronounced upon conviction, is falsified or reversed, all former proceedings are absolutely set aside, and the party stands as if he had never been at all accused; restored in his credit, his capacity, his blood, and his estates. But he still remains liable to another prosecution for the same offence. See Attainder, Judgment, and Outlawry.

Reverse of a medal, coin, &c. denotes the second, or back side; in opposition to the head or principal figure, called the face, or obverse.

F. Chamillart, a Jesuit, has an express dissertation on this point, whether or no the reverses of medals have always a regard to the emperors or empresses whose heads are represented on the front side of the medal? He says, that till of late the antiquaries have made no doubt of it; but that there are now several authors of another opinion.

The knowledge of the reverses of medals constitutes a distinguishing part of this science. In the early Greek coins, the reverse seldom affords much fancy of symbol; and in the imperial Greek coins it is chiefly impressed with temples of their deities. To Greek artists we are indebted for the beauty of the Roman imperial coins; and these are so highly finished, that on some reverses, as that of Nero's decursion, the "Adventus" and "Progressio" of various emperors, the "Fundator pacis" of Severus, the features of the emperor riding, or walking, are as exact as on the obverse. No Roman or Etruscan coins have been found of the globular form, or indented on the reverse, like the early Greek. The first Greek are small pieces of silver, while the Roman are large masses of copper: the former are struck, the latter are cast in moulds. The reverses of Roman coins are very uniform, the prow of a ship, a car, or the like, till about 100 years before our era, when various reverses appear on their consular coins in all metals. See Medal.

With respect to the consular medals, it is observed, that the same reverse is common to many of them; as Castor and Pollux on horseback, first used; then a victory, or one of the gods; or the person to whose honour the medal was struck, driving a chariot with two or four horses; whence the denomination of the denarius *bigatus,* and *quadrigatus.* The ratis or ship, or prow of a ship, as an emblem of naval power, was no uncommon reverse on the consular coins; which were, on this account, called *ratiti.* Some of the consular medals, that bore on the face the impress of their ancient kings, preserved on the reverse the record of some worthy action which they had performed, as the famous aqueduct on the reverse of Ancus, in honour of his having begun it. Medals, struck on occasion of founding colonies, have sometimes on the reverse a priest following a yoke of oxen, with a plough; designed to denote the manner in which the boundaries of colonies were marked out, or that they were planted by the common people; and those trophies that are sometimes seen on medals of this kind, signify that they were planted by the veteran soldiers.

The reverses of imperial medals are very various; but the chief of them may be reduced to three classes, *viz.* figures or personages; public monuments or buildings; and inscriptions. The figures are sometimes those of princes in miniature, whose portraits are exhibited more at large on the face; as on the reverses of the emperors of the family of Constantine, we often see the emperor standing with a labarum in his right hand, and a globe, surmounted with a victory, in his left. Sometimes the emperor is disguised under the figure of some god; as on the reverse of a Dioclesian, who had assumed the name Jovius, he appears in the figure of Jupiter, sitting in a chair, with a globe in his hand, surmounted with a Victory; the legend being iovi. h. u. c. c. *i. e. Hec voluerunt consules.* The Greek coins of cities present us with exquisite heads of deities, apparently copied from statues or paintings. The majesty of Jupiter, the modesty of Diana, the beauty of Venus, the ferocity of Mars, and other ideal characters, appear in the Grecian civic coins with a perfection not to be surpassed by human art. Sometimes the figure on the reverse is some relation of that on the face; as Augustus on the reverse of Julius, and Claudius on the reverse of his mother Antonia. Such medals are highly esteemed by antiquarians, not only because it is a rule with them that every coin stamped with portraits on either side is very valuable, but because they identify the personage on the reverse to have been the wife, the son, or the daughter of such a particular prince, and thus help in the adjustment of a series. The figure of some deity is sometimes seen on the reverse; as Minerva on the reverse of a Domitian; and the goddess Salus, with a patera in her hand, sacrificing to Esculapius, on the reverse of a Marcus Aurelius. (See Medal.) The virtues for which the emperors were, or wished to be, celebrated, are also frequently expressed by the figures on the reverses; and thus the fine personifications and symbols to be found on the reverses of the Roman coins render them entertaining, as well as instructive, to a person of poetical imagination. Virtue or Courage is represented by a bold armed woman with a spear in her right hand, and a parazonium in her left, on the reverse of a Domitian; Liberty, carrying in her right hand the cap of liberty, and in her left the wand called rudis or vindicta, appears on the reverse of a Commodus; and Equity, with a spear in her right hand, and a balance in her left, on the reverse of a Vespasian. The virtues of the ladies are also celebrated on the reverses of their medals; as Piety, in the habit of a Vestal virgin, strewing frankincense on an altar, on the reverse of a Faustina; Fœcunditas on another medal of the same, and SPES REIPUBLICÆ, expressed by a female figure, wearing a helmet to represent the republic, and two children at her breasts, on the reverse of a Maximiana Fausta, second wife of Constantine the Great. Happiness has sometimes the caduceus, or wand of Mercury, which Cicero (1 Offic.) tells us was thought to procure every wish. She has, in a gold coin of Severus, heads of poppy, to express that our chief bliss arises from oblivion of misfortune. Hope is represented as a sprightly damsel, walking quickly, and looking straight forwards. With her left hand she holds up her garments, that they may not impede the rapidity of her pace; while, in her right hand, she holds forth the bud of a flower, an emblem infinitely more fine than the trite one of an anchor, which is the symbol of patience, not of hope. This personification, with some others, must have been very familiar to the ancients, for often in this, and a few more instances, no name, as SPES AUG. or the like, is inserted in the legend. Abundance is imaged as a sedate matron, with a cornucopia in her hands, of which she scatters the fruits over the ground, nor does she hold up her cornucopia, and keep its contents to herself, as many modern poets and painters make her do. The emperor Titus, having cause to import a great supply of corn, during a scarcity at Rome, that supply, or the ANNONA, is finely represented as a sedate lady, with a full cornucopia in her left hand, which she holds upright, to indicate that she does not, however, mean to scatter it, as Abundance has a title to do, but to give it to Equity to deal out. This last circumstance is shewn by her holding a little image of Equity, known by her scales, and *hasta pura*, or pointless spear, in her right hand, over a basket filled with wheat. Behind the ANNONA is the prow of a ship, decked with flowers, to imply that the corn was brought by sea, (from Africa,) and that the ships had had a prosperous voyage. The best poet in the world could not have given us a finer train of imagery; and the best painter would be puzzled to express so much matter in so small a compass. Security stands leaning on a pillar, indicative of her being free from all designs and pursuits; and the posture itself corresponds to her name. Horace, in describing the wise man, mentions his being "teres atque rotundus," round and polished against all the rubs of chance;—an image seemingly derived from the column upon which this ideal lady reclines. The happiness of the state is pictured by a ship, sailing before a prosperous breeze; – an image, than which the superlative genius of Gray could not have found one more exquisite; and he has accordingly used it in his most capital production, "The Bard," with due success.

Provinces are also represented by figures or personages, denoting either the emperor's conquest or care of them; as Judæa sitting in a melancholy posture at the bottom of a pillar adorned with trophies, to signify her captive state, on the reverse of a Vespasian; and Italia with a cornucopia in her right hand, to denote her fruitfulness; a crown of towers on her head, to represent her many cities; a sceptre in her left hand, and sitting on a globe, to shew that she was sovereign of nations, on the reverse of a Commodus. Britain is often represented, upon the earliest imperial coins, sitting on a globe, with a symbol of military power, the *labarum*, in her hand, and the ocean rolling under her feet; —an emblem almost prophetic of the vast power which her dominion over the sea will always give her, provided that she asserts her element of empire with due vigour and perseverance, blending moderation and justice with her mighty power. On coins also we are presented with Achaia, Africa, Alamannia, Alexandria, Arabia, Armenia, Asia, Bithynia, Cappadocia, Dacia, Dardania, Egypt, Gallia, Hispania, Italia, Judæa, Macedonia, Mauritania, Pannonia, Parthia, Phrygia, Sarmatia, Sicily, Scythia, Syria, and the rivers Danube, Nile, Rhine, and Tiber. This personification of provinces, so interesting to the imagination, seems to have arisen from the figures of provinces carried in triumphs; as the personification of our old poets sprung from the ideal persons, actually represented in the mysterial plays. Whilst we are on the subject of the poetical imagery of ancient coins, we must not omit the mention, even, of a colonial one and of rude execution, of Augustus and Agrippa, inscribed IMP. and DIVI F. which has a high claim to merit in this way. On the reverse the conquest of Egypt is represented by the apposite metaphor of the crocodile, an animal almost peculiar to that country, and at that period esteemed altogether so, which is chained to a palm-tree, at once a native of the country and symbolic of victory. Moreover, the figure on the reverse is sometimes designed to immortalize some worthy action of the emperor; as the goddess Moneta, with a cornucopia in her left hand, and a balance in her right, on the reverse of a Domitian, to denote his care about the public coin. There are sometimes two, three, or more figures, on the same reverse; as Honos and Virtus on the reverse of Galba; and three kings, with the emperor crowning them, on a medal of Trajan. (See MEDAL.) There are also the figures of animals on the reverses of some medals; as the eagle and peacock, to denote the apotheosis of princes and princesses; the crocodile, as the symbol of Egypt; a serpent, of Esculapius; a camel, of Arabia, &c.; and elephants in trappings on the reverse of an Antoninus Pius and a Severus, importing that these emperors procured these beasts to entertain the people at the public shows. We meet also with fabulous animals, as the griffin on the reverse of one medal of Gallienus, a centaur on another, and a phœnix on some medals of Constantine and his sons, denoting the perpetuity of the empire.

The second sort of reverses comprehends public monuments and buildings; as the temple of Janus shut, on the reverse of a Nero, to signify the universal peace he gave to the empire; the Macellum, or shambles, which he caused to be erected, on another; the sumptuous bridge built by Trajan over the Tiber, on the reverse of one of his medals; and the Amphitheatre and Naval Column, on those of Titus.

The third sort of reverses includes inscriptions on the table or field of the medal. On several Latin and Greek imperial medals, we find nothing on the reverse but S. C. or Δ. E. for δημαρχικης εξυσιας, inclosed in a crown. Others represent signal occurrences; as VICTORIA GERMANICA IMP. VI. COS. III. on the reverse of M. Aurelius. Others have titles of honour granted to the princes; as S. P. Q. R. OPTIMO PRINCIPI, on the reverse of a Trajan, and also of an Antoninus Pius. Other inscriptions again have respect to public vows, which were made for the emperor every ten years, or sometimes, in the lower empire, every five years. Thus we have on the reverse of a Constantius VOTIS XXX. MULTIS XXXX. importing probably their engagement to make new vows at the expiration of thirty years, that he might reign forty years.

Besides the reverses already enumerated, there are others, called by Addison riddles, which cannot be referred to any of the above classes. Thus, Mercury in the form of a Terminus, standing on a thunder-bolt, on the reverse of an an Auguftus, was probably intended for a rebus, to exprefs the fenfe of that emperor's motto, *feftina lente.* Inftruments of religion were fymbols of the pontifex maximus, and fignified the piety of the prince, on whofe coin they appear; as the lituus, the fimpulum, the afperforium, and the capula, on the reverfe of a Nerva. Two hands joined, holding two ears of corn, and a caduceus betwixt them, on the reverfe of a Titus, import the good harmony and union fubfifting betwixt the prince and the public, the peace arifing from fuch an union, and the plenty, which is the fruit of fuch a peace. Pinkerton on Medals, 2 vols. Addifon's Three Series of Medals, in his Works, vol. i. p. 522, &c. See MEDALS.

REVERSE, in *Fencing*, a back-ftroke.

REVERSED, in *Heraldry*, a thing turned backwards, or upfide down.

REVERSED *Arms*, in *Military Language*, denote thofe whofe butts are flung or held upwards.

REVERSED *Talon*, in *Architecture*. See TALON.

REVERSING, or RENVERSING, in *Mufic*, the inverting of the order of the parts; that is, placing the higher part, or treble, in the room of the lower part or bafs.

Reverfing is frequently practifed in figurative counterpoint, where the bafs ferves as treble, and the treble at the fame time as bafs; and all this in fuch manner, as that the harmony, though very different, is yet as correct as before the reverfing, when the parts were in their natural order.

A reverfed fugue, or counter-fugue, called by the Italians *per contrarii movementi,* is when the guida falls, and the other, inftead of imitating by falling, imitates by rifing; or, it is a figure *per arfin et thefin.* See RENVERSÉ.

REVERSION, REVERSIO, in *Law*, is defined by Coke, a returning of lands, &c. into the poffeffion of the donor or his heirs, after the expiration of the term for which they were given or granted to another. Or, an eftate in reverfion, is the refidue of an eftate left in the grantor, to commence in poffeffion after the determination of fome particular eftate granted out by him.

The word has a double acceptation. The firft is, *jus revertendi, cum ftatus poffeffionis defecerit;* which is no more than an intereft in the land, when the occupation or poffeffion of it fhall fall.

The fecond is, when the poffeffion and eftate, which was parted with for a time, ceafeth, and is determined in the perfon of the alienees, affignees, grantees, or their heirs, or effectually returns to the donor, his heirs or affigns, whence it was derived.

This is the moft proper fignification of the word, which is derived from *revertor:* "Et apte dici non poteft reverfio, antequam revertatur in facto." Littlet.

The difference between a reverfion and a remainder confifts in this, that a remainder is general, and may remain or belong to any man but him that granteth or conveyeth the land, &c.

Whereas a reverfion is to himfelf, from whom the conveyance of the land, &c. proceeded, and is commonly perpetual as to his heirs alfo. And yet fometimes reverfion is confounded with remainder.

A reverfion is never created by deed or writing, but arifes from conftruction of law; a remainder can never be limited, unlefs by either deed or devife. But both are equally transferrable, when actually vefted, being both eftates *in præfenti,* though taking effect *in futuro.* The ufual incidents to reverfions, the doctrine of which is derived from the feudal conftitution, are faid to be fealty and rent. When no rent is referved on the particular eftate, fealty however refults of courfe, as an incident quite infeparable, and may be demanded as a badge of tenure, or acknowledgment of fuperiority, being frequently the only evidence that the lands are holden at all. Where rent is referved, it is alfo incident, though not infeparably fo, to the reverfion. (Co. Litt. 143.) The rent may be granted away, referving the reverfion; and the reverfion may be granted away, reverfing the rent, by fpecial words; but by a general grant of the reverfion, the rent will pafs with it, as incident to it; though by the grant of the rent generally, the reverfion will not pafs. The incident paffes by the grant of the principal, but not *e converfo;* for the maxim of law is, *acceforium non ducit, fed fequitur, fuum principale.* Co. Litt. 151, 152.

The law has carefully diftinguifhed remainders from reverfions. Thus, if one feized of a paternal eftate in fee makes a leafe for life, with remainder to himfelf and his heirs, this is properly a mere reverfion (Cro. Eliz. 321.), to which rent and fealty fhall be incident; and which fhall only defcend to the heirs of his father's blood, and not to his heirs general, as a remainder limited to him by a third perfon would have done (3 Lev. 407.); for it is the old eftate, which was originally in him, and never yet was out of him. And fo, likewife, if a man grants a leafe for life to A, referving rent with reverfion to B and his heirs, B hath a remainder defcendible to his heirs general, and not a reverfion to which the rent is incident; but the grantor fhall be entitled to the rent during the continuance of A's eftate. 1 And. 23.

For the affiftance of thofe who have an eftate in remainder, reverfion, or expectancy, after the death of others, againft fraudulent concealments of their deaths, it is enacted by 6 Ann. c. 18. that all perfons, on whofe lives any lands or tenements are holden, fhall (upon application to the court of chancery and order made thereupon) once in every year, if required, be produced to the court or its commiffioners; or, upon neglect or refufal, they fhall be taken to be actually dead, and the perfon entitled to fuch expectant eftate may enter upon and hold the lands and tenements, till the party fhall appear to be living.

It may further be obferved, that whenever a greater eftate and a lefs coincide and meet in one and the fame perfon, without any intermediate eftate, the lefs is immediately annihilated; or, in the law phrafe, is faid to be *merged,* that is, funk or drowned in the greater. Thus, if there be tenant for years, and the reverfion in fee-fimple defcends to or is purchafed by him, the term of years is merged in the inheritance, and fhall never exift any more. But they muft come to one and the fame perfon in one and the fame right; elfe, if the freehold be in his own right, and he has a term in right of another (*en auter droit*), there is no merger. Therefore, if tenant for years dies, and makes him who hath the reverfion in fee his executor, whereby the term of years vefts alfo in him, the term fhall not merge; for he hath the fee in his own right, and the term of years in the right of the teftator, and fubject to his debts and legacies. So alfo, if he who hath the reverfion in fee marries the tenant for years, there is no merger; for he hath the inheritance in his own right, the leafe in the right of his wife. An eftate-tail is an exception to this rule: for a man may have in his own right both an eftate-tail and a reverfion in the fee; and the eftate-tail, though a lefs eftate, fhall not merge in the fee. For eftates-tail are protected and preferved from merger by the operation and conftruction, though not by the exprefs words, of the ftatute *de donis:* which operation and conftruction have probably arifen upon this confideration; that, in the common cafes of merger of eftates for life or years by uniting with the inheritance, the particular tenant hath the fole intereft in them, and hath full power at any time

to

to defeat, destroy, or surrender them to him that hath the reversion; therefore, when such an estate unites with the reversion in fee, the law considers it in the light of a virtual surrender of the inferior estate. But in an estate-tail the case is otherwise: the tenant for a long time had no power at all over it, so as to bar or to destroy it; and now can only do it by certain special modes, by a fine, a recovery, and the like: it would, therefore, have been strangely improvident, to have permitted the tenant in tail, by purchasing the reversion in fee, to merge his particular estate, and defeat the inheritance of his issue: and hence it has become a maxim, that a tenancy in tail, which cannot be surrendered, cannot also be merged in the fee. Blackst. Comm. b. ii.

Reversion *of Series*, in *Algebra*, is the method of finding the value of an unknown quantity, whose powers enter the terms of a finite or infinite series, by means of another series, in which it does not enter. Thus, if we have

$$y = ax + bx^2 + cx^3 + dx^4 + \&c. \text{ or}$$
$$y = ax^m + bx^{m+p} + cx^{m+2p} + dx^{m+3p} + \&c.$$

or if we have

$$\alpha y + \beta y^2 + \gamma y^3 + \delta y^4 + \&c. =$$
$$ax + bx^2 + cx^3 + dx^4 + \&c.$$

and we can find in these, and other similar cases,

$$x = Ay + By^2 + Cy^3 + Dy^4 + \&c.$$

the original series is said to be reverted. The reversion of series was first proposed by Newton, in a letter to Mr. Oldenbourgh, at that time secretary to the Royal Society, with directions to have it communicated to Leibnitz, and in which the author gave one of the earliest proofs of his great analytical powers. It was afterwards published in his "Analysis per Equationes Numero terminorum Infinitas," and has since engaged the attention of many of the most profound analysts; and accordingly different methods have been suggested for this purpose; but that of M. Arbogast, in his "Calcul des Derivations," is the most complete. We have already, under the article *Calculus of* Derivations, explained, as far as was consistent with the plan of this work, the nature of the symbols, notation, and principles of this doctrine; and we may, therefore, under the present article, give that author's formulæ for reversion, referring the reader for the first principles to the article above-mentioned. Still, however, as many of our readers would probably wish to see the same in its plainer English dress, we propose, in the first instance, to shew the methods commonly employed for this purpose by our own algebraists. This consists in assuming a series of a *proper form* for the required unknown quantity, and then substituting the powers of this series, instead of the powers of that quantity, in the proposed series, and finally equating the co-efficients, whereby the values of the indeterminate or unknown co-efficients, above represented by A, B, C, D, &c. will be obtained.

Let $y = ax + bx^2 + cx^3 + dx^4 + ex^5 + \&c.$ be the proposed series, and

$$x = Ay + By^2 + Cy^3 + Dy^4 + Ey^5 + \&c.$$

the assumed reverted series; then, by substituting the several powers of this series, instead of the powers of x in that proposed, we have

$$y = \left\{ aAy + \left.\begin{matrix} aB \\ + bA^2 \end{matrix}\right\} y^2 \left.\begin{matrix} + aC \\ + 2bAB \\ + CA^3 \end{matrix}\right\} y^3 \left.\begin{matrix} + aD \\ + 2bAC \\ + bB^2 \\ + 3cA^2B \\ dA^2 \end{matrix}\right\} y^4 \left.\begin{matrix} + aE \\ + 2bad \\ + 2bBC \\ + 3cA^2C \\ + 3cAB^2 \\ + 4dA^3B \\ + eA^5 \end{matrix}\right\} y^5 + \&c. \right.$$

Consequently we have $aA = 1$, and each of the other co-efficients equal to zero, it being a known property of two identical functions, that the co-efficients of the like powers of the indeterminate quantity are equal to each other; and since, on the first side of the above expression, y enters only simply, it follows, that all the powers of y on the other side must have their co-efficients equal to zero. Whence we have

$$aA = 1$$
$$aB + bA^2 = 0$$
$$aC + 2bAB + CA^3 = 0$$
$$aD + 2bAC + bB^2 + 3cA^2B + dA^4 = 0$$
$$\&c. \qquad \&c.$$

and hence, again, we have

$$A = \frac{1}{a}$$

$$B = -\frac{b}{a^3}$$

$$C = \frac{2b^2 - ac}{a^5}$$

$$D = -\frac{5b^3 - 5abc + a^2d}{a^7}$$

$$E = \frac{14b^4 - 21ab^2c + 3a^2c^2 + ba^2bd - a^3e}{a^9}$$

$$\&c. \qquad \&c.$$

And since a, b, c, d, &c. are known in the original series, the numeral values of A, B, C, D, &c. in the reverted series are thus determined.

With regard to the *proper form* of the assumed series, we may observe, generally, that in order to find the first term of the reverted series, the rule is, to substitute y^n instead of x in the proposed series, and to equate the least power of y arising from this substitution with unity, which will give the required value of n; and as for the indices of the other powers they will be the same multiples of the above value of n, as they are (in the original series) of *unity*.

Let there be proposed, for example,

$$z = x^m + bx^{m+p} + cx^{m+2p} + dx^{m+3p}, \&c.$$

Here, in order to determine the form of the series to be assumed, let z^n be wrote for x in the given equation, according to the usual method; and then the exponents, supposing z transposed, will be 1, nm, $nm + np$, $nm + 2np$, $nm + 3np$, &c. respectively; of which, the two least (1 and nm) being made equal to each other, n is found $= \frac{1}{m}$; and the differences are $\frac{p}{m}$, $\frac{2p}{m}$, $\frac{3p}{m}$, &c. Whence the series to be assumed is

$$x = z^{\frac{1}{m}} + Bz^{\frac{1+p}{m}} + Cz^{\frac{1+2p}{m}} + Dz^{\frac{1+3p}{m}} + \&c.$$

(for it is evident, by inſpection, that the co-efficient (A) of the firſt term muſt here be an unit).

This ſeries being therefore raiſed to the ſeveral powers of x, in the given equation, and the co-efficients of the homologous terms in the new equation compared together, it will be found that,

$$B = -\frac{b}{m}$$

$$C = -\frac{(1 + m + 2p)b^2 - 2mc}{2m^2}$$

$$D = -\frac{(2m^2 + 9mp + 9p^2 + 3m + 6p + 1)b^3}{6m^3} + \frac{(1 + m + 3p)bc}{m^2} - \frac{d}{m}, \text{ \&c.}$$

From the general value of x, found above, innumerable theorems, for reverſing particular forms of ſerieſes, may be deduced.

Thus, if $x + bx^2 + cx^3 + dx^4$ &c. $= z$; then (m being $= 1$, and $p = 1$) x is $= z - bz + (2bb - c)z^3 - (5b^3 - 5bc + d)z^4$ &c.

And, if $x + bx^3 + cx^5 + dz^7 +$ &c. $= z$; (m being $= 1$, and $p = 2$) $x = z - bz^3 + (3bb - c)z^5 - (12b^3 - 8cb + d)z^7$ &c.

Alſo, if $x^{\frac{1}{2}} + bx^{\frac{3}{2}} + cx^{\frac{5}{2}} + dx^{\frac{8}{2}}$, &c. $= z$; then (m being $= \frac{1}{2}$, and $p = 1$) $x = z^2 - 2bz^4 + (7bb - 2b)z^6 - (30b^3 - 18bc + 2d)z^3$ &c. &c.

It may be obſerved, that in all theſe forms of ſerieſes, the firſt term is without a co-efficient (which renders the concluſion much more ſimple). Therefore, when the ſeries to be reverted has a co-efficient in its firſt term, the whole equation muſt be firſt divided thereby. Thus, if the equation was $3x - 6x^2 + 8x^3 - 13x^4$ &c. $= y$; by dividing the whole by 3 it will become $x - 2x^2 + \frac{8x}{3} - \frac{13x^4}{3}$ &c. $= \frac{1}{3}y$; where, putting $z = \frac{1}{3}y$, we have, by For. 1. $x = z + 2z^2 + \frac{16}{3}z^3$ &c. $= \frac{y}{3} + \frac{2y^2}{9} + \frac{16y^3}{81}$ &c.

When there are two ſeries, conſiſting of like powers of x and y, as

$$ax + bx^2 + cx^3 + \text{ \&c.} = \alpha y + \beta y^2 + \gamma y^3 + \text{ \&c.}$$

aſſume, as in the preceding caſes,

$$x = Ay + By^2 + Cy^3 + Dy^4 + \text{ \&c.}$$

and let his, and its powers, be ſubſtituted for x, and the powers of x, and we ſhall have

$$\alpha y + \beta y^2 + \gamma y^3 + \delta y^4 + \text{ \&c.} =$$

$$aAy + \left.\begin{matrix} aB \\ bA^2 \end{matrix}\right\} y^2 + \left.\begin{matrix} aC \\ + 2bAB \\ + cA^3 \end{matrix}\right\} y^3 + \left.\begin{matrix} aD \\ + 2bAC \\ + bB^2 \\ + 3cA^2B \\ + dA^4 \end{matrix}\right\} y^4 + \text{ \&c.}$$

in which, inſtead of equating all our co-efficients to zero, they muſt now be equated to $\alpha, \beta, \gamma, \delta, \varepsilon$, &c.; that is

$$\begin{aligned} &aA = \alpha \\ &aB + bA^2 = \beta \\ &aC + 2bAB + cA^3 = \gamma \\ &aD + 2bAC + bB^2 + 3cA^2B + dA^4 = \delta \\ &\quad\text{\&c.} \qquad\qquad\qquad \text{\&c.} \end{aligned}$$

Whence we have the following values of A, B, C, D, &c. *viz.*

$$A = \frac{\alpha}{a}$$

$$B = \frac{\beta - bA^2}{a}$$

$$C = \frac{\gamma - 2bAB - cA^3}{a}$$

$$D = \frac{\delta - bB^2 - 2bAC - 3cA^2B - dA^4}{a}$$

$$E = \frac{- 2bBC - 2bAD - 3cAB^2 - 3cA^2C - 4dA^3B - eA^5}{a}$$

whence the values of A, B, C, D, &c. become determined as before.

In all the above caſes, the ſeveral co-efficients a, b, c, d, &c. are conceived to be totally independent of each other, and when this is the caſe, that is, when no ſpecific law obtains between them, it is obvious, that we can proceed no farther in the practical ſolution than we have derived terms in the theoretical inveſtigation; but if, as moſt commonly happens, the ſeries we are deſirous of reverting ariſe from the expanſion of any function, ſo that an uniform law is obſerved between its ſeveral co-efficients; a ſimilar law may frequently be diſcovered in the reverted ſeries, though this generally depends rather upon an induction than from any peculiar form under which the reverted co-efficients ariſe, which is indeed the great imperfection of this method of reverſion.

Let us take, for example, the ſeries

$$x + \frac{x^2}{2} + \frac{x^3}{3} + \frac{x^4}{4} + \frac{x^5}{5} \text{ \&c.} = z,$$

to find the value of x in terms of z.

This agrees with our firſt form; where $a = 1$, $b = \frac{1}{2}$, $c = \frac{1}{3}$, $d = \frac{1}{4}$, &c. and we have

$$\frac{1}{a} = 1$$

$$- b = -\frac{1}{2}$$

$$+ (2b^2 - ac) = \frac{1}{2} = \frac{1}{3} = \frac{1}{6} = \frac{1}{2 \cdot 3}$$

$$- (5b^3 - 5abc + a^2d) = \frac{1}{24} = \frac{1}{2 \cdot 3 \cdot 4}$$

$$+ (14b^4 - 21ab^2c + 3a^2c^2 + 6a^2bd - a^3e) = \frac{1}{120} = \frac{1}{2 \cdot 3 \cdot 4 \cdot 5}.$$

And hence, inferring the ſame law to have place throughout, we have

$$x = z - \frac{1}{2}z^2 + \frac{1}{2 \cdot 3}z^3 - \frac{1}{2 \cdot 3 \cdot 4}z^4 + \frac{1}{2 \cdot 3 \cdot 4 \cdot 5}z^5 - \text{ \&c.}$$

We muſt not, however, look for the like uniformity of reſult in all caſes. As an example of the contrary, let there be propoſed the ſeries

$$x - \frac{1}{2}x^2 + \frac{1}{2 \cdot 3}x^3 - \frac{1}{2 \cdot 3 \cdot 4}x^4 + \frac{1}{2 \cdot 3 \cdot 4 \cdot 5}x^5 - \text{ \&c.}$$
$$= \frac{1}{2}y + \frac{1}{3}y^2 + \frac{1}{4}y^3 + \frac{1}{5}y^4 + \frac{1}{6}y^5 + \text{ \&c.}$$

to find x in terms of y.

Here

$$\text{Here } a = 1,\ b = \frac{1}{2},\ c = \frac{1}{2 \cdot 3},\ d = \frac{1}{2 \cdot 3 \cdot 4},\ \text{\&c.}$$

$$\alpha = \frac{1}{2},\ \beta = \frac{1}{3},\ \gamma = \frac{1}{4},\ \delta = \frac{1}{5},\ \text{\&c.}$$

whence

$$\frac{\alpha}{a} = \frac{1}{2} = \mathrm{A}$$

$$\frac{\beta - b\,\mathrm{A}^2}{a} = \frac{11}{24} = \mathrm{B}$$

$$\frac{\gamma - 2b\,\mathrm{A\,B} - c\,\mathrm{A}^3}{a} = \frac{11}{24} = \mathrm{C}$$

$$\frac{\delta - b\,\mathrm{B}^2 - 2b\,\mathrm{A\,C} - 3c\,\mathrm{A}^2\mathrm{B} - d\,\mathrm{A}^4}{a} = \frac{1381}{2880} = \mathrm{D}$$

$$\frac{\varepsilon - 2b\,\mathrm{B\,C} - 2b\,\mathrm{A\,D} - 3c\,\mathrm{A\,B}^2 - \text{\&c.}}{a} = \frac{1543}{3840} = \mathrm{E}$$

whence the propofed feries is

$$x = \frac{1}{2}y + \frac{11}{24}y^2 + \frac{11}{24}y^3 + \frac{1381}{2880}y^4 + \frac{1543}{3840}y^5 + \text{\&c.}$$

in which no law of continuation can be difcovered, either by induction, or otherwife.

In this refpect the fymbols and notation of Arbogaft have a decided advantage, as by thefe means the law of formation in the reverted feries is exhibited in the cleareft poffible point of view. Taking for example our firft feries, under the form

$$y = \beta x + \gamma x^2 + \delta x^3 + \varepsilon x^4 + \text{\&c.}$$

$$\text{to find } x = b y + c y^2 + d y^3 + e y^4 + \text{\&c.}$$

Here the general refult is expreffed by

$$x = \beta^{-1} y + \frac{1}{2} \cdot \mathrm{D} \cdot \beta^{-2} \cdot y^2 + \frac{1}{3}\genfrac{}{}{0pt}{}{\mathrm{D}^2}{\mathrm{C}} \cdot \beta^{-3} \cdot y^3 + \frac{1}{4}\genfrac{}{}{0pt}{}{\mathrm{D}^3}{\mathrm{C}} \cdot \beta^{-4} \cdot y^4 + \text{\&c.}$$

where the law is clearly expreffed by means of the fymbol D; and if it be requifite, the co-efficients may be eafily expreffed in terms of β, γ, δ, &c. thus $\beta^{-1} = \beta^{-1}$.

$$\frac{1}{2}\mathrm{D} \cdot \beta^{-2} = -\beta^{-3}\gamma = \frac{-\gamma}{\beta^3}$$

$$\frac{1}{3} \cdot \genfrac{}{}{0pt}{}{\mathrm{D}^2}{\mathrm{C}} \cdot \beta^{-3} = \frac{1}{3 \cdot 2} \cdot \mathrm{D}\,(-3\,\beta^{-4} \cdot \gamma)$$

$$= \frac{1}{3 \cdot 2}(-3 \cdot -4\,\beta^{-5} \cdot \gamma^2 - 3\,\beta^{-4} \cdot 2\,\delta)$$

$$= 2\,\beta^{-5} \cdot \gamma^2 - \beta^{-4} \cdot \delta = \frac{2\gamma^2 - \beta\delta}{\beta^5}$$

$$\frac{1}{4} \cdot \genfrac{}{}{0pt}{}{\mathrm{D}^3}{\mathrm{C}} \cdot \beta^{-4} = \frac{1}{4}\Big(\mathrm{D}\,\beta^{-4} \cdot \genfrac{}{}{0pt}{}{\mathrm{D}^2}{\mathrm{C}} \cdot \gamma + \genfrac{}{}{0pt}{}{\mathrm{D}^2}{\mathrm{C}} \cdot \beta^{-4} \cdot \mathrm{D} \cdot \gamma^2 + \genfrac{}{}{0pt}{}{\mathrm{D}^3}{\mathrm{C}} \cdot \beta^{-5} \cdot \gamma^3\Big)$$

$$= \frac{1}{4}\Big(4\,\beta^{-5} \cdot \varepsilon + \frac{4 \cdot 5}{1 \cdot 2}\beta^{-6} \cdot 2\gamma\delta - \frac{4 \cdot 5 \cdot 6}{1 \cdot 2 \cdot 3}\beta^{-7} \cdot \gamma^3$$

$$= \frac{5\beta\gamma\delta - 5\gamma^3 - \beta^2\varepsilon}{\beta^7}$$

which will be found to agree with our former refult.

We refer the reader who may not be acquainted with the ufe and fignification of the above fymbols and notation, to our article DERIVATIONS.

In thefe formulæ the quantities β, γ, δ, &c. although totally independent, are yet apparently connected by means of the fymbol of derivation D; but the application is generally made to feries which exprefs the evolution of fome function, and the co-efficients of which feries are confequently formed after a certain law: for inftance

$$1 + x + \frac{x^2}{1 \cdot 2} + \frac{x^3}{1 \cdot 2 \cdot 3} + \text{\&c.}$$

is the evolution of e^x, and if y be put

$$= 1 + x + \frac{x^2}{1 \cdot 2} + \frac{x^3}{1 \cdot 2 \cdot 3} + \text{\&c.}$$

then, by the theorem for reverfion,

$$x = \beta^{-1}(y - 1) + \frac{1}{2}\mathrm{D} \cdot \beta^{-2} \cdot (y-1)^2 + \frac{1}{3}\genfrac{}{}{0pt}{}{\mathrm{D}^2}{\mathrm{C}} \cdot \beta^{-3} \cdot (y-1)^3\ \text{\&c.}$$

but in the propofed form

$$\beta = 1 \,.\, \mathrm{D} \,.\, \beta = \frac{1}{1 \cdot 2} \cdot \genfrac{}{}{0pt}{}{\mathrm{D}^2}{\mathrm{C}} \cdot \beta = \frac{1}{1 \cdot 2 \cdot 3},\ \text{\&c.}$$

$$\text{therefore } x = (y-1) - \frac{1}{2}(y-1)^2 + \frac{1}{3}(y-1)^3 - \text{\&c.}$$

And in the fame way from reverfion, if

$$z = x + \frac{x^3}{2 \cdot 3} + \frac{3x^5}{5 \cdot 8} + \text{\&c.}$$

$$\text{by reverfion}\quad x = z - \frac{z^3}{1 \cdot 2 \cdot 3} + \frac{z^5}{1 \cdot 2 \cdot 3 \cdot 4 \cdot 5} - \text{\&c.}$$

We refer the reader for more on this fubject to Woodhoufe's "Principles of Analytical Calculation," and Arbogaft's "Calcul des Derivations;" and for the principles of the method ftated in the former part of this article, to Simpfon's "Fluxions," vol. ii. p. 302; Maclaurin's Algebra, p. 263. See alfo Newton's "Analyfis per Equationes," aad Bonnycaftle's Algebra, vols. i. and ii.

REVERSIONS, in the *Doctrine of Annuities*, are either contingent or abfolute. (For the former fee the article SURVIVORSHIPS.) Of abfolute reverfions, the cafes are very few, and the folutions fimple and eafy. An *abfolute* reverfion, whether it is to take place after the extinction of a fingle life, or of any number of lives, or after the expiration of a given number of years, muft neceffarily be more valuable, in general, than a *contingent* reverfion; which, depending on events altogether uncertain, will be of lefs value in proportion as thofe events are lefs probable. The following problems include the principal cafes of abfolute reverfions, and their folutions being almoft felf-evident, require no explanation.

PROBLEM I.

To find the value of the reverfion in fee of an annuity after a given number of years.

Solution.—Deduct the value of an annuity for the given term from the perpetuity; multiply the remainder into the annuity, and the product will be the value required.

Example.—Let the annuity be 15*l.* the term 15 years, and the rate of intereft 4*l.* *per cent.* By Tab. III. (fee ANNUITIES) the value of an annuity for 15 years is 11.118, which being deducted from 25 (the perpetuity), the remainder, or 13.882, multiplied into 15 (the given annuity),

nuity), produces 208.23*l.* or 208*l.* 4*s.* 7*d.* nearly for the value required.

Corollary.—In like manner, the value of an annuity for a given term of years, after the expiration of another term, may be obtained by ſubtracting the value for the preſent term from the value during the preſent and reverſionary terms: thus, the value of an annuity of 10*l.* during 15 years, after the expiration of 12 years, is found by ſubtracting 9.385 (the value for 12 years at 4*l. per cent.* by Tab. III. ANNUITIES) from 16.329 (the value by the ſame table for 27 years), and multiplying 6.944, the difference, into 10; which produces 69.440*l.* or 69*l.* 8*s.* 10*d.* nearly for the value required.

PROB. II.

To find the value of the reverſion in fee of an eſtate, or annuity, after the extinction of a given life.

Solution.—Deduct the value of an annuity on the given life from the perpetuity; multiply the remainder into the annual produce of the eſtate, or into the annuity, and the product will give the value ſought.

Example.—Let the annual produce of the eſtate or annuity be 18*l.* the age of the poſſeſſor of ſuch eſtate or annuity 35, and the rate of intereſt 3*l. per cent.* By Tab. VI. (LIFE-*Annuities*), the value of an annuity on a life of 35, at 3*l. per cent.* is 15.938. The perpetuity, at the ſame rate, is 33.333; the difference between theſe two values, or 17.395, multiplied into 18, produces 313.110*l.* or 313*l.* 2*s.* 2*d.* for the anſwer.

Corollary.—The reverſion in fee after two or three joint lives, or after the longeſt of two or three lives, is found in the ſame manner, by deducting the values of thoſe lives from the perpetuity. Thus the value of two joint lives, aged 30 and 35, by Tab. VIII. (LIFE-*Annuities*), at 3*l. per cent.* is 12.131, which being deducted from 33.333, and multiplied into 5, will give 106.01*l.* or 106*l.* 0*s.* 2*d.* for the value of the reverſion in fee of an eſtate of 5*l. per annum* after the extinction of thoſe *joint* lives. In like manner, the value of the reverſion in fee of an eſtate of 10*l. per annum,* after three joint lives, aged 30, 35, and 40 years, and computing at 4 *per cent.* may be found by Prob. IV. (LIFE-*Annuities*) to be 163.81*l.* or 163*l.* 16*s.* 2*d.*; and after the longeſt of thoſe three lives, it may be found by Prob. V. (LIFE *Annuities*) to be 59.980*l.* or 59*l.* 19*s.* 7*d.* nearly.

PROB. III.

To find the value of a given *ſum,* payable on the extinction of a given life.

Solution.—Deduct, as in the preceding problem, the value of an annuity on the given life from the perpetuity; multiply the remainder by the given ſum, and divide the product by the perpetuity increaſed by unity; the quotient will be the anſwer.

Example.—Let the ſum be 1000*l.* the age of the given life 45 years, and the rate of intereſt 5*l. per cent.* By Tab. VI. (LIFE-*Annuities*), the value of an annuity, on a life of 45, at 5 *per cent.* is 11.105, which being deducted from 20, the perpetuity, leaves 8.895. This remainder, multiplied into 1000, and divided by 21, gives 423.571*l.* or 423*l.* 11*s.* 5*d.* for the value required.

In the ſame manner may be found the value of a given ſum, payable on the extinction of two or three joint lives, or of the longeſt of two or three lives. Thus, the value of two joint lives, of 40 and 50, at 4 *per cent.* by Tab. IX. (LIFE-*Annuities*), being 8.834; the difference between this value and 25, the perpetuity, will be 16.166; which being multiplied into 1000, and the product divided by 26, will give 621.77*l.* or 621*l.* 15*s.* 5*d.* for the preſent value of 1000*l.* payable on the extinction of thoſe joint lives. Again, by the rule in the article on LIFE-*Annuities*, and Tables VI. and IX. the value of an annuity on the longeſt of two lives, aged 40 and 50, at 4 *per cent.* may be found equal to 15.627, which being deducted from 25, and the remainder multiplied into 1000, will produce 9373, and this, divided by 26, will give 360.5*l.* or 360*l.* 10*s.* for the value of 1000*l.* payable on the deceaſe of the ſurvivor of thoſe two lives.

Remark.—It will be obſerved, that the value of the reverſion of an *annuity* is greater than the value of the reverſion of a *ſum,* in the proportion of 1*l.* increaſed by its intereſt for a year to 1*l.*; or, which is the ſame thing, in the proportion of the perpetuity increaſed by unity to the perpetuity. In the one caſe, the payment of the annuity becomes due at the end of the year, in which the life or lives become extinct; in the other caſe, the ſum only becoming payable at the end of that year, the annual intereſt upon it cannot be received till the end of the ſucceeding year. See Dr. Price's Treatiſe on Reverſionary Payments. Note E, Appendix.

PROB. IV.

To find the value of an annuity for a given term of years after the extinction of any number of lives.

Solution.—Subtract the value of an annuity on the life or lives from the perpetuity; multiply the remainder into the preſent value of an annuity for the given term, and divide the product by the perpetuity; the quotient multiplied into the annuity will be the value ſought.

Example.—Let it be required to determine the value of an annuity of 10*l.* for 20 years, which is not to commence till the extinction of a life of 25, reckoning intereſt of money at 5 *per cent.*. By Tab. VI. (LIFE-*Annuities*) the value of an annuity on a life of 25, is 13.567; this value, ſubtracted from 20, and multiplied into 12.4622, the value of an annuity for 20 years, by Tab. III. (ANNUITIES) produces 80.1693; which being divided by 20, and the quotient multiplied into 10, gives 40.085*l.* or 40*l.* 1*s.* 9*d.* nearly for the anſwer. By proceeding in the ſame manner, the value of an annuity of 15*l.* for 25 years, after the extinction of two *joint* lives, aged 30 and 40, and after the longeſt of thoſe lives, computing at 4 *per cent.* may be reſpectively found to be equal to 136*l.* and 70*l.* 8*s.* 2*d.* by Tab. VI. and IX. (LIFE-*Annuities*), and Tab. III. (ANNUITIES).

PROB. V.

To find the value of an annuity after the deceaſe of a given life, or of any number of lives, during the continuance of another life, or of any number of lives, to be nominated at the time of ſuch deceaſe.

Solution.—This differs very little from the preceding problem, and is anſwered much in the ſame manner. Subtract the value of an annuity, on the life or lives, from the perpetuity; multiply the remainder into the value of the life or lives at the time of their nomination, and alſo into the given annuity; divide the product by the perpetuity, and the quotient will be the anſwer.

Example.—Required the value of an annuity of 100*l.* after the deceaſe of a perſon aged 30, during the continuance of the life of a perſon to be nominated at the time of ſuch deceaſe, whoſe age may be ſuppoſed to be then about 15 years, reckoning intereſt of money at 4*l. per cent.*

By Tab. VI. the value of a life of 30 is 14.781, which being ſubtracted from 25, and the remainder multiplied into 16.791 (the value by the ſame table of an annuity on a life of 15), and alfo into 100, the given annuity produces 17.158.7. This fum, divided by 25, gives 686.3*l.* or 636*l.* 6*s.* for the value fought.

If, inftead of a fingle life of 30, the annuity had been to commence after the longeft of two lives, aged 30 and 35, to continue during the longeft of two lives, fuppofed to be 10 and 15 years of age at the time of the deceafe of the former lives, the prefent value in that cafe, at the fame rate of intereft, would be, according to the values in Tab. VI. and VIII. (LIFE-*Annuities*), equal to 583.234*l.* or 583*l.* 4*s.* 8*d.* nearly. See Simpfon's Select Exercifes; Dr. Price's Treatife on Reverfionary Payments; and Mr. Morgan's Doctrine of Life Annuities.

REVERT, in *Law*. A thing is faid to revert when it returns or falls back to its firft owner.

All honours and royal fees alienated revert to the crown, or are revertible. Apanages, or portions of younger fons of kings, are granted on condition of reverfion.

REVERTENS, Lat. returning or defcending: as, *Ductus revertens, conducimento, ritornante*, all imply a regular defcent of found; which the Italians likewife call *defcendente di grado.*

REVERTER, *Formedon in the*, in *Law*. See FORMEDON.

REVES, JAMES DE, in *Biography*, a learned Dutch Proteftant divine and profeffor, the fon of a Dutch burgomafter of Deventer, was born in 1586. While he was very young he was taken to Amfterdam, where he was inftructed in the Latin, Greek, and French languages, and then fent to purfue his ftudies at the univerfity of Leyden. From this place he removed to the univerfity of Franeker, where he learned the Hebrew under the two Drufiufes. In 1610 he travelled into France for farther improvement, where he refided two years, chiefly at Saumur, Rochelle, and Orleans. He next entered upon the duties of the Chriftian miniftry, and was, in 1641, chofen principal and firft profeffor of the theological college of the ftates of Holland and Weft Friefland at Leyden. He died at Leyden in 1658, at the age of 72. His works are very numerous, of which the titles are given in the General Biography: among thefe may be mentioned, "Belgicarum Ecclefiafticarum Doctrina et Ordo," &c.; "Hiftoria Pontificum Romanorum contracta, et ad Annum 1632 contracta;" "Daventriæ illuftratæ, five Hiftoriæ Urbis Daventrienfis, Lib. vi." 1651, 4to. De Reves publifhed an improved edition of "The Book of Pfalms," in Dutch verfe, by Peter Dathænus, and he was concerned in revifing the Dutch verfion of the Old Teftament, which was printed at Leyden in 1637.

REVETEMENT, in *Fortification*, is a ftrong wall built on the outfide of the rampart and parapet, to fupport the earth, and prevent its rolling into the ditch. See CORDON.

REVEZ, in *Geography*, a town of Portugal, in the province of Tras os Montes; 10 miles N.E. of Lamego.—Alfo, a town of France, in the department of the Sambre and Meufe; 20 miles S. of Bruffels.

REUGNY, a town of France, in the department of the Indre and Loire; 9 miles N.E. of Tours.

REVIERS, a town of France, in the department of the Calvados; 8 miles N. of Caen.

REVIEW, in *Chancery*. A *bill of review* is where the caufe has been heard, and a decree therein figned and enrolled; but fome error in law appears in the body of the decree, or fome new matter is difcovered in time, after the decree made. A bill of review is not exhibited but by leave of the court.

A *commiffion of review* is a commiffion fometimes granted, in extraordinary cafes, to revife the fentence of the court of delegates; when it is apprehended they have been led into a material error. This commiffion the king may grant, although the ftatutes 24 and 25 Hen. VIII. declare the fentence of the delegates definitive; becaufe the pope, as fupreme head by the canon law, ufed to grant fuch commiffions of review; and fuch authority, as the pope heretofore exerted, is now annexed to the crown by ftats. 26 Hen. VIII. cap. 1. and 1 Eliz. cap. 1. But this is not matter of right, which the fubject may demand *ex debito juftitiæ*, but merely a matter of favour, and which, therefore, is often denied. See APPEAL.

REVIEW, in *Literary Hiftory*. See JOURNAL and MAGAZINE.

REVIEW, in *Military Language*, is the appearance of an army, or part of an army, arranged in form of battle, and exercifed, in prefence of the king or of a general. The firings in reviews are generally thirty-fix rounds, *viz.* by companies; by grand divifions; by fub-divifions; obliquely, advancing, retreating; by files; in the fquare; ftreet-firings, advancing and retreating; and, laftly, a volley.

The intention of a review is to know the condition of the troops, and to fee that they are complete, and that they perform their exercife and evolutions well.

REVIGNY, in *Geography*, a town of France, in the department of the Meufe, and chief place of a canton, in the diftrict of Bar-fur-Ornain; 15 miles S. of St. Menehould. The place contains 1800, and the canton 9087 inhabitants, on a territory of $162\frac{1}{2}$ kiliometres, in 17 communes.

REVILING *the Ordinances of the Church*, in *Law*, is an offence punifhable by ftatute. Thus it is provided by 1 Edw. VI. cap. 1 and 1 Eliz. cap. 1. that whoever reviles the facrament of the Lord's fupper fhall be punifhed by fine and imprifonment. See COMMON *Prayer*.

REVILLA GIGEDO, in *Geography*, an ifland in the North Pacific ocean, nearly of an oval form, 50 miles long from N. to S., and 23 in breadth. Capt. Vancouver called it by this name from refpect to Conde de Revilla Gigedo, viceroy of New Spain. N. lat. 55° 6′ to 55° 55′. E. long. 228° 27′ to 229° 15′.

REVILLA *Gigedo, Canal of*, a ftrait of the North Pacific ocean, between the forementioned ifland and that of Gravina.

REVILLY, a town of France, in the department of the Indre; 9 miles N. of Iffoudun.

REVIN, a town of France, in the department of the Ardennes, on the Meufe; 6 miles N.E. of Rocroy.

REVINGHEIM, a town of France, in the department of the North; 5 miles N. of Bailleul.

REVISE, among *Printers*, a fecond proof of a fheet to be printed, taken off after correcting the firft.

REVIVAL *of perfons hanged*. See EXECUTION.

REVIVER. See REVIVOR.

REVIVIFICATION, RESUSCITATION, or *Reduction*, in *Chemiftry*, the art of reftoring a mixed body to its firft ftate, after it had been altered and difguifed by diffolution, calcination, and the like. See REDUCTION, and the feveral metals.

REVIVIFIED ANTIMONY. See ANTIMONY.

REVIVING, in *Law*, a renewing of rents and actions after they had been extinguifhed.

REVIVOR, or REVIVER, *Bill of*, is where a bill has been exhibited in chancery againft one who anfwers: but, before the caufe is heard, or at leaft before the decree is enrolled, one of the parties dies.

In this cafe, a bill of revivor muft be brought, praying the

the former proceedings may ftand revived, and be put in the fame condition as at the time of the abatement.

REUNION, *Ifle de la*, in *Geography*. See Bourbon.

REVOCATION, Revocatio, in *Law*, the act of revoking, calling back, or annulling, a power, grant, &c. made before.

The revocation of an offer, after it is accepted of, is invalid. All preceding wills or teftaments are revoked by the laft; but the republication of a former will revokes one of a later date, and eftablifhes the firft again.

The cancelling or revoking of a teftament is one of the three ways of avoiding it. For, though I make a laft will and teftament irrevocable in the ftrongeft words, yet I am at liberty to revoke it, becaufe my own act or words cannot alter the difpofition of law, fo as to make that irrevocable which is in its own nature revocable. (8 Rep. 82.) For this, fays lord Bacon (Elem. c. 19.) would be for a man to deprive himfelf of that which of all other things is moft incident to human condition; and that is, alteration or repentance. It hath alfo been held, that without an exprefs revocation, if a man, who hath made his will, afterwards marries and hath a child, this is a prefumptive or implied revocation of his former will, which he made in his ftate of celibacy. (Ld. Raym. 441. 1 P. Wms. 204.) The Romans were alfo wont to fet afide teftaments as being "inofficiofa," deficient in natural duty, if they difinherited or totally paffed by (without affigning a true and fufficient reafon) any of the children of the teftator. (Inft. 2. 18. 1.) But if the child had any legacy, however fmall, it was a proof that the teftator had not loft his memory or his reafon, which otherwife the law prefumed; but was then fuppofed to have acted thus for fome fubftantial caufe; and, in fuch cafe, no "querela inofficiofi teftamenti" was allowed. Hence probably has arifen that groundlefs vulgar error of the neceffity of leaving the heir a fhilling, or fome other exprefs legacy, in order to difinherit him effectually: whereas the law of England makes no fuch conftrained fuppofition of forgetfulnefs or infanity; and, therefore, though the heir or next of kin be totally omitted, it admits no "querela inofficiofi" to fet afide fuch a teftament.

The revocation of a devife of lands and tenements muft be in writing, figned by the teftator, or fome other perfon in his prefence, and by his exprefs direction; and be fubfcribed, in his prefence, by three or four credible witneffes.

A prior clauftral is revocable at pleafure. The revocation of the edict of Nantes was fatal to the French Proteftants.

REVOCATION *of Ufes*. See Use.

REVOLAX, in *Geography*, a town of Sweden, in the government of Ulea; 13 miles E. of Braheftad.

REVOLSKOI, a town of Ruffia, in the government of Viborg; 128 miles N.W. of Povenetz.

REVOLUTION, formed from *revolvo, to roll backwards*, in *Politics*, denotes a grand turn or change of government.

There are no ftates in the world but have undergone frequent revolutions. The abbot de Vertot has furnifhed us with two or three good hiftories of the revolutions of Sweden, the revolutions of Rome, &c.

The Revolution, ufed with us by way of eminence, denotes the great turn of affairs in England in 1688, when king James II. abdicating, the prince and princefs of Orange were declared king and queen of England, &c. See *Right of* Crown.

The declaration of the prince of Orange, which was difperfed over the kingdom previoufly to his arrival, and which was received with univerfal approbation, contained an enumeration of the grievances of the nation, and the ftatement of which evinced the abfolute neceffity of a change in the government. Thefe grievances were the difpenfing and fufpending power exercifed by the king; the court of ecclefiaftical commiffion; the filling of all offices with Catholics, and the raifing of a Jefuit to be privy-counfellor; the open encouragement given to popery, by building every where churches, colleges, and feminaries for that fect; the difplacing of judges, if they refufed to give fentence according to orders received from court; the cancelling of the charters of all the corporations, and the fubjecting of elections to arbitrary will and pleafure; the treating of petitions, even the moft modeft, and from perfons of the higheft rank, as criminal and feditious; the committing of the whole authority of Ireland, civil and military, into the hands of papifts; the affuming of an abfolute power over the religion and laws of Scotland, and openly exacting in that kingdom an obedience without referve; and the violent prefumptions againft the legitimacy of the prince of Wales. The redrefs of thefe grievances was the prince's profeffed object; and for this purpofe he propofed to have a loyal and free parliament affembled, in order to provide for the fafety and liberty of the nation, as well as to examine the proofs of the prince of Wales's legitimacy. The prince, at the fame time avowed, that he had no other defign than to procure the full and lafting fettlement of religion, liberty, and property. On the moment of alarm the Englifh minifters redreffed fome of the grievances of which complaint had been made; but there ftill remained the foundation of all grievances upon which they could again in an inftant be erected, an arbitrary and defpotic power in the crown. For this ufurpation there was no poffible remedy, but by a full declaration of all the rights of the fubject, in a free parliament. On the 21ft of October 1688, the prince fet fail from Helvoetfluys, with a fleet of near 500 veffels, and an army of above 14,000 men. A ftorm drove him back, but he foon repaired his lofs, and made fail with a fair wind towards the weft of England. The fame wind detained the king's fleet in its ftation near Harwich, and enabled the Dutch to pafs the ftraits of Dover without oppofition. Both fhores were covered with multitudes of people, who, befides admiring the grandeur of the fpectacle, were held in anxious fufpenfe by the profpect of an enterprize, the moft important, which, during fome ages, had been undertaken in Europe. The prince had a profperous voyage, and landed his army fafely in Torbay, on the 5th of November, (1688,) the anniverfary of the gunpowder treafon. The firft perfon who joined the prince was major Buerington; and he was quickly followed by the gentry of the counties of Devon and Somerfet. Sir Edward Seymour made propofals for an affociation, which every one figned. By degrees, the earl of Abingdon, Mr. Ruffel, fon of the earl of Bedford, Mr. Wharton, Godfrey, Howe, came to Exeter. All England was in commotion. Lord Delamere took arms in Chefhire, the earl of Danby feized York, the earl of Bath, governor of Plymouth, declared for the prince, and the earl of Devonfhire made a like declaration in Derby. The nobility and gentry of Nottinghamfhire embraced the fame caufe; and every day there appeared fome effect of that univerfal combination into which the nation had entered againft the meafures of the king. Even thofe who took not the field againft him, were able to embarrafs and confound his counfels. A petition for a new parliament was figned by 24 bifhops and peers of the greateft diftinction, and was prefented to the king. No one thought of oppofing or refifting the invader. The army deferted him; and feveral officers of diftinction informed Feverfham, the general, that they could not in confcience

fight

fight against the prince of Orange. Prince George of Denmark and the princess Anne abandoned the king: an event which, concurring with several other incidents that had occurred, and which threatened the overthrow of his royal authority, occasioned an alarm approaching to consternation, and a grief that caused him to shed tears. In this state of distress, deserted by his friends and family, and despised by his enemies, he was as much depressed, as he had before been vainly elated by prosperity. He issued writs for a new parliament, and deputed commissioners to treat with the prince of Orange. The king every day more and more alarmed by accounts of the general disaffection that prevailed, and misled by imprudent counsel operating upon his fears, precipitately embraced the resolution of escaping into France, having sent before him the queen and the infant prince. Nor before his departure did he provide for the exercise of the administration; he threw the great seal into the river, and recalled all the writs that had been issued for the election of the new parliament. During this temporary dissolution of government, the populace became masters, rose in a tumult, destroyed the mass-houses, and even attacked and rifled the houses of the Florentine envoy and Spanish ambassador, where many Catholics had lodged their valuable effects. Having discovered Jefferies, the chancellor, notwithstanding the disguise he had assumed in order to fly the kingdom, they so abused him that he died soon after. Feversham disbanded the troops, and without either disarming or paying them, let them loose to prey upon the country. In this extremity, the bishops and peers, who were in town, assembled, and having chosen the marquis of Halifax speaker, gave directions to the mayor and aldermen for keeping the peace of the city, and issued orders, which were readily obeyed, to the fleet, the army, and all the garrisons; and they made applications to the prince of Orange, whose enterprize they highly applauded, and whose success they joyfully congratulated. The prince, availing himself of the popularity of his cause, approached nearer and nearer to London. In the mean while the king, though disguised, was discovered and seized by the populace at Feversham, where he was attempting to make his escape, and soon after arrived in London. Whilst he remained at Whitehall he received few marks of attention and respect; and whilst he remained there the Dutch guards took possession of the palace. In consequence of a message conveyed to him from the prince by Halifax, Shrewsbury, and Delamere, which commanded him to leave the palace, he removed to Ham, a seat of the duchess of Lauderdale's. Having obtained permission he retired to Rochester, where he remained for some days. But finding that the church, the nobility, the city, the country, all concurred in neglecting him, and leaving him to his own counsels, he submitted to his melancholy fate; and being urged by earnest letters from the queen, he privately embarked on board a frigate which waited for him; and he arrived safely at Ambleteuse in Picardy, whence he hastened to St. Germains. The prince, in compliance with an address from about 90 peers and bishops, summoned a convention, which completed the revolution.

The true ground and principle upon which that memorable event proceeded, was an entirely new case in politics, which had never before happened in our history; the abdication of the reigning monarch, and the vacancy of the throne thereupon. Accordingly, in a full assembly of the lords and commons, met in *Convention* (which see) on occasion of this vacancy, both houses came to this resolution (Jan. 22, 1689): "That king James the Second, having endeavoured to subvert the constitution of the kingdom, by breaking the original contract between king and people; and, by the advice of Jesuits, and other wicked persons, having violated the fundamental laws; and having withdrawn himself out of this kingdom, has abdicated the government, and that the throne is thereby vacant."

The facts themselves thus appealed to, *viz.* the king's endeavour to subvert the constitution, by breaking the original contract, his violation of the fundamental laws, and his withdrawing himself out of the kingdom, were evident and notorious: and the consequences drawn from these facts (namely, that they amounted to an abdication of the government (see ABDICATION); which abdication did not affect only the person of the king himself, but also all his heirs, and rendered the throne absolutely and completely vacant) it belonged to our ancestors to determine. For, whenever a question arises between the society at large and any magistrate vested with powers originally delegated by that society, it must be decided by the voice of the society itself: there not being upon earth any other tribunal to which to resort. And that these consequences were fairly deduced from these facts, our ancestors have solemnly determined, in a full parliamentary convention representing the whole society. The reasons upon which they decided may be found at large in the parliamentary proceedings of the times, our ancestors having most indisputably a competent jurisdiction to decide this great and important question, and having in fact decided it, it is now become our duty at this distance of time to acquiesce in their determination; being born under that establishment which was built upon this foundation, and obliged, by every tie, religious as well as civil, to maintain it.

The lords and commons having determined this fundamental article, that there was a vacancy of the throne, proceeded to fill up that vacancy in such manner as they judged the most proper. And this was done by their declaration of the 12th of February, 1689, in the following manner: "That William and Mary, prince and princess of Orange, be, and be declared king and queen, to hold the crown and royal dignity during their lives, and the life of the survivor of them; and that the sole and full exercise of the regal power be only in, and executed by, the said prince of Orange, in the names of the said prince and princess, during their joint lives; and after their deceases the said crown and royal dignity to be to the heirs of the body of the said princess; and for default of such issue, to the princess Anne of Denmark, and the heirs of her body; and for default of such issue, to the heir of the body of the said prince of Orange." This transaction, founded in equity, and strictly agreeable to the spirit of our constitution, and the rights of human nature, formed a new era in the history of our country, in which the bounds of prerogative and liberty have been better defined, the principles of government more thoroughly examined and understood, and the rights of the subject more explicitly guarded by legal provisions, than in any other period of the English history.

To the settlement of the crown was annexed a declaration of rights, in which all the points that had, of late years, been disputed between the king and people were finally determined; and the powers of royal prerogative were more narrowly circumscribed and more exactly defined than in any former period of the English government. It is worthy of observation, says judge Blackstone, that the convention avoided with great wisdom the wild extremes into which the visionary theories of some zealous republicans would have led them. They held that this misconduct of king James amounted to an *endeavour* to subvert the constitution; and not to an actual subversion, or total dissolution of the government, according to the principles of Mr.

Locke (Gov. p. 2. c. 19.); which would have reduced the ſociety almoſt to a ſtate of nature; would have levelled all diſtinctions of honour, rank, offices, and property; would have annihilated the ſovereign power, and in conſequence have repealed all poſitive laws; and would have left the people at liberty to have erected a new ſyſtem of ſtate upon a new foundation of polity. They therefore very prudently voted it to amount to no more than an abdication of the government, and a conſequent vacancy of the throne; by which the government was allowed to ſubſiſt, though the executive magiſtrate was gone, and the kingly office to remain, though king James was no longer king. Thus the conſtitution was kept entire; which, upon every ſound principle of government, muſt otherwiſe have fallen to pieces, if ſo principal and conſtituent a part as the royal authority had been aboliſhed, or even ſuſpended. Blackſt. Comm. book i, &c. book iv. Hume's Hiſt., vol. viii.

Revolution, *French*, in its moſt popular ſenſe, was for ſeveral years, after 1789, underſtood in England to conſiſt of thoſe events which at the outſet deſtroyed the uſual order of things, *viz.* the Pariſians' revolt, the capture and deſtruction of the Baſtile, and the ſubmiſſion of the monarch. But theſe events, ſingular and important as they were, could not conſtitute a political revolution: this muſt have required a change in the government. It is capable, ſays Mr. (now ſir James) Mackintoſh, of three ſenſes. The king's recognition of the rights of the ſtates-general to a ſhare in the legiſlation, was a change in the actual government of France, where the whole legiſlative and executive power had, without the ſhadow of interruption, for nearly two centuries, been enjoyed by the crown; in that ſenſe, the meeting of the ſtates-general was the revolution, and the 5th of May 1789 was its epoch. The union of the three orders in one aſſembly was a moſt important change in the forms and ſpirit of the legiſlature. This, too, may be called the revolution: and the 23d of June of the ſame year will be its epoch. This body, thus united, formed the new conſtitution, which may be called a revolution; becauſe, of all the early political changes, it was the moſt important, and its epoch was determined by the concluſion of the labours of the National Aſſembly, on the 30th of September 1791, when the king, Louis XVI., came to the aſſembly, and having addreſſed the members, the preſident proclaimed in his own name, and in the name of the whole body, that "the conſtituent aſſembly declares that its power is at an end, and that it will ſit no longer." In whatever ſenſe the phraſe be taken, the effects have been ſo momentous, as to claim the attention, and excite the awe of the whole civilized world. In a work of this kind it is impoſſible to enter into the detail of the various events connected with the French revolution: theſe muſt require the pen of the hiſtorian, who can devote years to the inveſtigation of facts, and to the developement of the motives by which the great actors have been impelled to engage in the ſeveral parts connected with their names. The hiſtory of the French revolution will afford ample ſcope and abundant materials for the moſt intereſting narrative of modern times. The New Cyclopædia, embracing every topic connected with human knowledge, cannot devote much ſpace to the hiſtory of any country, and ſtill leſs to a ſingle event connected with an individual ſtate. In the articles France and Lewis XVI. we have given a pretty full account of the cauſes which led to the French revolution, and of the changes which took place previouſly to the deſtruction of the Baſtile: of the confederacy of the crowned heads againſt the popular governments, which were eſtabliſhed, one after another, on the ruins of the old conſtitution: of the proſcriptions and maſſacres which were perpetrated in Paris; and finally, of the decapitation of the king, queen, and the king's ſiſter. We have then traced the progreſs of Bonaparte, from his conſulſhip to the high dignity of emperor, and noticed the vaſt and unprecedented power to which he attained over almoſt the whole continent of Europe, mentioning the kings that had been created by his fiat, and the ſtates that had been ſubject to his controul, or that ſtood in awe of his power. This mighty conqueror we followed, in the article France, to his divorcement of Joſephine, and marriage with the daughter of the emperor of Germany.

In addition to the above-named articles, to which the reader is referred, we have now to trace the ſteps of this man from the year 1810, to his expulſion from the throne and empire of France, and ſhew by what means his obſtinacy and ambition cauſed him to fall from the higheſt dignities, to which perhaps mortal man ever arrived, to a ſtate of mortification and almoſt inſignificance as the exile to Elba, which may be regarded as the end of the revolution.

For ſome time the very nature of commerce muſt have operated as much to the prejudice of his own merchants, as they could do to the prejudice of the merchants of this country; he ſtruck more directly and fatally at the liberty of his ſubjects by his decrees reſpecting priſons, domeſtic ſervants, and the preſs.

In the decree reſpecting priſons, to which we referred in the article France, it was explicitly declared, that there were many perſons, in that country, accuſed of crimes againſt the ſtate, whom it was neither ſafe to liberate nor to bring to trial: for the purpoſe of keeping theſe priſoners in ſafe cuſtody, a number of ſtrong priſons were reared in the heart of the country, in which it was determined they ſhould be confined. There might have been ſome plea for this mode of conduct during the convulſions of the revolution:—then it might not have been ſafe nor prudent either to have brought to trial, or to have liberated men whoſe popular character, or cauſe, probably would, in the one caſe, have excited freſh diſturbances; and in the other have aſſured their acquittal, however ſtrong and full the proofs of their guilt might have been. But under the exiſting order of things it was impoſſible for the emperor of France to pronounce a ſtronger libel on his own government, than could be inferred from ſuch a decree. At this time, indeed, he reigned with the moſt deſpotic ſway over the French, and he ſeemed reſolved to eſtabliſh, in the heart of Europe, and over a people enlightened by ſcience, a deſpotiſm unknown even to the ignorant and enſlaved nations of the Eaſt. By his decree reſpecting ſervants it was evident, that its object was not to be confined to perſons in that condition of life, but that it was meant, by putting them under ſuch ſtrict and harſh regulations, to have always at command ſpies in every family,—and thus to eſtabliſh a more regular and perfect ſyſtem of eſpionage. To theſe acts he iſſued his mandate, which went to deſtroy every advantage which attaches to a free preſs: this, indeed, was not calculated to excite aſtoniſhment, for in all deſpotic countries the liberty of the preſs has been the object of the tyrant's fear and hatred. At no period did France ever enjoy a free preſs; but Bonaparte, who ſeems to have examined and compared all the tyrannical proceedings and meaſures of deſpotic governments, both ancient and modern, with a view to improve upon them, and from them to eſtabliſh a perfect ſyſtem in France, which ſhould cruſh the powers of the human mind, had gone beyond all former precedent. By his decrees in the year 1810, of which we are ſpeaking, only a certain number of printers were allowed to carry on their buſineſs within the French territories, and theſe were to be under the moſt ſtrict and watchful

ful superintendance of the police; so that nothing could be printed, but what government thought proper to allow and sanction. This has always been the object in despotic countries; but it was obtained with great difficulty, and never with such perfect success as was desired. By diminishing the number of printers, Bonaparte removed the chief difficulty towards destroying the liberty of the press, and succeeded in placing France in a state of mental bondage, perhaps without a parallel in the history of the world.

During this period the emperor of France was employing his troops in Spain, with a view of subjugating that country and Portugal, and uniting the whole peninsula to his already too vast empire. By the exertions chiefly of Great Britain his plans were frustrated. Bonaparte seems, indeed, to have been completely thrown out of his expectations and calculations with respect to the resistance, which he met with in his designs on the independence of Spain; and the protracted and obstinate nature of the contest proved that for a considerable length of time he carried on the war there in a desultory manner, by armies apparently unconnected with each other, and by means not acting in concert and co-operation. About the beginning of 1811, however, a regular plan appears to have been formed by Bonaparte for conducting the war in Spain. The principal feature in this plan was the occupancy of the chief cities in the peninsula: and at the end of the year the French had made considerable progress, they had taken possession of most of the chief towns in Spain; their progress had been slow, attended with great difficulty, interrupted with many reverses, and purchased at heavy expences; still they had made progress, and the emperor, if he could accomplish his objects, never regarded the cost.

In the domestic history of France, the only thing that occurred worthy of notice was the birth of a son to the emperor, who was immediately designated as king of Rome, and in that character received the servile homage of the legislators of the empire. It was the subject of frequent remark, that after the second marriage of Bonaparte, he for many months seemed to abandon his restless and ambitious projects (with the exception of his attempts on Spain), or that he took much longer time for their execution. During the year 1811, rumours of war between France and Russia frequently arose, and as frequently subsided without any act of hostility on either side. It was not till the spring of 1812 that the war commenced, which was ultimately the cause of the overthrow of the French emperor.

On the 9th of May, 1812, Bonaparte set out from St. Cloud, on the 6th of June he crossed the Vistula, and on the 22d of that month he formally declared war against Russia; two days after this he crossed the Niemen, entered the Russian territories, and immediately commenced hostilities by the capture of Kowno, and on the 28th he entered Wilna, the capital of Russian Poland. In this war he expected considerable assistance from the Poles; he knew their rooted enmity to Russia, and though he had already deceived them, in the expectations which he had led them to form of his erecting Poland again into a kingdom, yet he well knew how to inspire them again with confidence in him: as soon, therefore, as he had entered Poland, his first public act was to proclaim it anew. A diet was immediately assembled, a constitution framed, and the name and form of liberty were restored to the Poles.

Bonaparte had not been long in Russia before he began to experience the disasters of the climate. In the month of July, and when his army was not much farther north than Wilna, a tremendous tempest arose; torrents of rain fell; thousands of his horses perished, and many pieces of artillery were buried in the mud. His disappointment and chagrin began to manifest themselves; he broke out into invectives on the barbarity of the Russians for laying waste their country in their retreat. Although many severe battles were fought, still the Russians refused to hazard a general engagement. Their perseverance in the plan of retreating astonished the world, and mortified, beyond conception, their enemies, who had no means of preventing this kind of warfare. It was imagined, that for a short time only they would follow up this system, and that their steadiness, passive courage, and patriotism would give way, when they perceived the enemy advancing, notwithstanding their obstinate perseverance, the advanced state of the season, and the desolation of the country. But Russia was animated with one soul, the dread and detestation of the French rose superior to every feeling: considerations of personal interest or comfort, even the sight of their families driven from their homes, and those homes abandoned to the enemy or the flames, had no room in the breast of the Russians: there dwelt only the determination to expel the French, and to obey every command of their sovereign, issued by him or his generals for that purpose. The proclamations of Alexander encouraged the enthusiasm and animated the patient and heroic sufferings of the people; they said, that the emperor was determined to make no peace with Bonaparte, while his legions polluted the soil of Russia: that he would sacrifice all, even Petersburg and Moscow, rather than they should fall into the hands of the enemy. In all the proclamations of Alexander there was no irresolution, no despondence, no expression, that could lead Bonaparte to indulge the hope, that he would propose, or even listen to terms of peace; or his subjects to apprehend, that he would not persevere in what he had begun. New levies were ordered to be raised; the Russian people were invoked by all those powerful feelings and prejudices, which ignorance and superstition create; and when a Russian is told, that what he has to do, or to suffer, is for the sake of his sovereign or his religion, he is made insensible to danger and misery.

Kutusoff continued his retreat, at the head of the main Russian army, till he arrived at Borodino, within a short distance of Moscow. The position here was extremely favourable for defence; though it did not cover the capital, as there were other roads leading to it. On the 7th of September the famous battle of Borodino was fought; it continued from six in the morning till night, when the French, though masters of one part of the field, retreated. The loss on this occasion was immense; not less than 60,000 men are supposed to have fallen on both sides. Both sides claimed the victory; and at Petersburg it was imagined, that Moscow was rendered perfectly secure by the defeat of the enemy. The French, however, retreated, only for the purpose of meeting a strong reinforcement which was advancing, and which actually arrived within a day or two of this tremendous engagement. At the head of these he put himself, and prepared to march by another road for Moscow. As soon as the Russian general was informed that Bonaparte had been reinforced, and that he was manœuvring to get to Moscow by turning the Russians, he resolved to abandon that capital to its fate. Bonaparte therefore advanced to Moscow unmolested, but on his entrance into the city, on the 11th of September, he found its governor and inhabitants animated with the true Russian spirit. They made every resistance in their power to the entrance of the enemy: a great part of the effective population was armed, and as soon as the

advanced

advanced guard of the enemy appeared they attacked them in the ſtreets, and from the houſes, impeding their progreſs, and cauſing great deſtruction; and, when it was no longer practicable to prevent the entrance of the enemy, the city was ſet on fire, and, as it was built principally of wood, the fire ſpread rapidly in all directions; and before the French could ſtop the progreſs of the flames, only a tenth part of it remained unconſumed. It is impoſſible to deſcribe or even imagine the diſappointment, mortification, and wrath of Bonaparte when he beheld Moſcow in flames. He had promiſed his ſoldiers reſt from their fatigues, refreſhments, proviſions in abundance, and comfortable winter-quarters in it. Theſe were now all at an end: amidſt the ruins of Moſcow his army would in vain ſeek for ſhelter from the inclemencies of the approaching winter, or for a ſupply of proviſions. His indignation ſoon broke out in conduct at once tyrannical, cruel, and mean: he ſeized on the men who had ſet fire to the city, and cauſed them to be executed.

The ſituation of the French army in Moſcow was now moſt critical: they were ſurrounded with armies almoſt as numerous as themſelves, and which were daily increaſing. Winter was already making its appearance: the troops had been completely worn down by their long march, and at the end of it, they had met with a reception which neither their leader nor they could have anticipated. The former was certain in his own mind that a complete victory muſt be the reſult of the battle of Borodino, and that, as a price of peace, Alexander would find a ſupply for all their wants, at the expence of his own ſubjects. Inſtead of this, the victory was not at all deciſive, and Bonaparte advanced with the moſt cautious ſteps into Moſcow, well knowing, by a fatal experience, that he beheld an enemy in every Ruſſian he met. He ſoon ſaw that he could not remain in the ruins of the city till ſpring ſhould open to him a communication with the ſouthern provinces; and if they retreated, how were they to obtain proviſions, and endure a march of 500 miles in a ſevere and deſolating winter, through deep ſnows, and by the hidden and almoſt impaſſable roads of Ruſſia? The Ruſſian generals, true to the cauſe of their country, and inſpired by the animating proclamations of their emperor, took the moſt active meaſures to force Bonaparte from Moſcow, by cutting off his ſupplies; and when they had compelled him to retreat, to haraſs him in every inch of his journey. For this purpoſe a great number of Coſſacks, beſides thoſe who had been already employed, were collected, and this was the ſeaſon of their utility and triumph.

Bonaparte was now ſenſible of the dreadful error he had committed: unleſs he actually expected to dictate terms of peace at Moſcow, it was the extreme of madneſs to have proceeded thither at the beginning of a Ruſſian winter; and if he did expect either to dictate terms of peace, or to have his own offers accepted, he muſt have been ignorant of the determined hatred which all ranks in Ruſſia bore towards him. The apology he offers in his bulletins, for his military career in Ruſſia, is a paltry one; according to him, the Ruſſian winter this year commenced earlier than uſual; as if the circumſtance of the froſt ſetting in a very few days ſooner or later could have ſaved or deſtroyed his army! What muſt be the military prudence of that man, who calculates for the ſafety of his army, and the ſucceſs of his meaſures, on ſo uncertain a thing as climate! The fact is, Bonaparte, in all his former campaigns, had been indebted for his ſucceſs to the boldneſs of his advances into the very heart of the enemy's country; that this boldneſs did not aſſume the character, deſerve the name, and produce the conſequences of raſhneſs, was leſs owing to his own foreſight and circumſpection than to the puſillanimity, treachery, and want of talents of his opponents: without adverting to the different circumſtances in which he was placed in Ruſſia, from a difference of climate and national character, he followed his uſual plan, thus proving that he was defective in one great feature of a man of abilities, the adaptation of general principles and plans to particular circumſtances.

Perceiving that, though he was in the heart of the Ruſſian empire, and amidſt the ruins of its ancient capital, no terms of peace were propoſed, and that the Ruſſians were gathering round him on all ſides, he ſent to Kutuſoff to propoſe terms of accommodation, or, at leaſt, an armiſtice. The Ruſſian commander received the French negociator in the midſt of his generals, and replied to him with the utmoſt frankneſs: he told him, that he was not authoriſed to receive any propoſals either for peace, or an armiſtice; that he would not even ſend to Alexander nor receive the letter which Bonaparte had ſent; and that, with reſpect to an armiſtice, the Ruſſian army had no occaſion for it, and they were in poſſeſſion of too many advantages to throw them away by accepting it. The negociator then began to complain of the ſavage manner in which the war had been conducted; to this Kutuſoff replied in language which ought always to be had in remembrance by invaders: "The French (he ſaid) had introduced the barbarities of which they complained; they had commeneced hoſtilities without reaſon; had invaded Ruſſia; had inflicted as much miſery on its inhabitants as they could; and now, when vengeance and retaliation were at hand, they wiſhed for peace; peace muſt not even be mentioned till the invaders had retraced their ſteps, and had again croſſed the Viſtula; Bonaparte had nothing to do but get out of Moſcow how he could, ſince he came thither without being invited; the Ruſſians, he might depend upon it, would do their duty,—and the duty which they owed their ſovereign, their country, their murdered or deſolate wives and helpleſs children, demanded that they ſhould make their invaders ſuffer as much miſery as poſſible: Bonaparte had proclaimed the campaign at an end at Moſcow, but with the Ruſſians it was only beginning." At another time, when the French complained of the exceſſes of the Coſſacks, who had even fired upon their flags of truce, they were told by the Ruſſian general that the Coſſacks acted according to orders: "we want," ſaid he, "not to hear of parleys; our object is to fight, not to negociate; take your meaſures accordingly." Perceiving that there was no chance of peace, or an armiſtice, and that the Ruſſians were fully ſenſible of their own power, and of the reduced and miſerable ſtate of the French army, and had formed their plans in ſuch a manner, as to take the utmoſt advantage of their own good fortune, Bonaparte, after having been upwards of a month in Moſcow, prepared for his retreat. A retreat of greater difficulty, and accompanied with more miſery, has never been recorded in the annals of hiſtory. On the firſt days of it, the ſufferings of the ſoldiers were feelingly and accurately deſcribed in an intercepted letter from the viceroy of Italy. "Three days of ſuffering have ſo broken down the ſpirits of the ſoldiers, that I look upon them, at the preſent moment, as ſcarcely capable of making any effort whatever. Many of them have died of hunger or of cold; many others have gone and ſurrendered themſelves to the enemy." The ſufferings of the French, however, were greatly to be increaſed by hunger, and the ſeverity of the climate.

Early in November the Ruſſian winter ſet in with more than its accuſtomed rigour: hitherto the roads had been only deep and heavy, now they became ſo exceſſively ſlippery, that the men could ſcarcely keep their feet: hitherto the horſes, neceſſary both for the artillery and for the ſuſtenance

of

of the soldiers, for they were compelled and glad to feed on horse flesh, had proceeded feebly and slowly on, or dropped dead only, a few hundreds every day; but the first day of the frost, nearly 30,000 perished. All possibility of carrying forward their artillery was now at an end; the spirits of the soldiers completely deserted them: they crawled on, exposed to the most dreadful cold, exhausted with fatigue and hunger, emaciated, and almost naked. The road was literally blocked up with the dead and the dying: they had no power to defend themselves against the Cossacks, who constantly hovered round them: they had no inclination to do it: death to them would have been a blessing: at the sight of the Cossacks they hoped their miseries would soon be terminated: but their enemies were not so merciful as to put them to death; piercing them with wounds, stripping off the little covering they had, they left them on the snow, there bleeding and naked, exposed to the rigours of a Russian winter. Whenever the French entered any village where there was the least chance of repose or food, they exerted their little remaining strength, and crawled on their hands and feet to seek it. Frequently, just as they had stretched out their hands to seize a little food, or reached the threshold of a wretched hut, under which they looked for shelter from the weather, perhaps for a few minutes sleep, the remnant of their strength failed them, and they expired.

With what feelings and sentiments did they now regard Bonaparte! No longer the adored general, who seemed to have chained victory to his car, to be more than mortal, and to be destined to render all Europe subservient to the interests and glory of France; they cursed him as the author of all the misery under which they were writhing; on his person they willingly would have inflicted vengeance; but sensible of their indignation, he had gathered round his person his principal officers, mounted on almost the only horses that remained. For some time he rode in a coach, till the dreadful voice of his soldiers commanded him to walk as they did, and to share their fatigue; he still, however, defended himself from the inclemency of the weather with a cloak; "off with your cloak" was another stern command, that he durst not disobey. Such was the situation,—such the feelings of the French army during their dreadful retreat, in which every thing that could accumulate or sharpen misery beset them. It scarcely needed the presence of an enemy to complete the work of destruction; the climate of Russia, aided by hunger, was amply sufficient.

In fact, the French soldiers could no longer be said to compose an army; they were straggling in all directions, anxious indeed to avoid the Cossacks, since from them they experienced only an aggravation of their misery, but not unwilling to fall in with the regular Russian troops, in the hope of being taken prisoners, or falling in battle. Their ignorance of the country, and the state of the roads, were such, that the different divisions of the French army could not support one another; and frequently when expecting to fall in with the main body, they encountered the enemy and were taken prisoners. On the 10th of November, before they reached Smolensk, general Augereau, with 2000 men and 60 officers, surrendered themselves; this was the first instance, during the present war, of a whole corps laying down their arms. It is computed that in three days time, prior to that date, they lost 20,000 men, besides nearly 20,000 more that fell in the previous engagements; nearly 300 pieces of cannon had also either fallen into the hands of the Russians, or had been spiked and buried by the French. But these losses, enormous as they were, were only preludes to greater ones.

It is extremely difficult to form an estimate of the loss of the French in this dreadful campaign. The Russian official accounts state that they took upwards of 150,000 men; and it was calculated that the number of killed, and of those who perished by hunger, fatigue, and cold, amounted nearly to 100,000; so that reckoning that the French army when it crossed the Niemen, and began the campaign, amounted to 300,000 men, scarcely more than 50,000 escaped out of Russia; and of those, a large proportion must have suffered so dreadfully as to be absolutely unfit for future service. Such is a bare outline of this disastrous campaign, the consequences of which have proved so important to the liberties of Europe. In it we have seen the first general of his age, at the head of one of the finest armies that was ever raised, and which placed in him the most unbounded confidence, flying, beaten, disgraced, bereft of the greatest part of his troops, and the object of detestation to the remainder. This is an event which, taken under all its circumstances, cannot be parallelled in history. No war, ancient or modern, exhibits such destruction and misery; more, no doubt, have fallen in the field, in the course of a campaign; but no army ever perished with such lingering and varied misery. The cause of the failure of the Russian campaign under the auspices of that same general, who had on almost all great occasions been successful before, is the business of the historian to investigate, and will long afford matter for speculation and curious discussion. "It has scarcely ever fallen to the lot of the historian or annalist," says the intelligent writer in the New Annual Register, "to narrate such disasters; and when we consider that these disasters befel a man who, from a low station in society, had raised himself to the very summit of power, to an extent of dominion and influence never before witnessed in Europe; that this man, for the purpose of a mad, bloody, and desperate ambition, had trampled on all the laws and usages of justice and civilized society; and that he considered himself, and called upon the world to acknowledge and fear him, as absolutely beyond the reach of fate, as something more than mortal; when we moreover reflect on the peculiar interest which this country felt in all that befel him, since against this country was his most implacable and deadly hatred directed; and from that hatred, his ruin indirectly originated; when we take all these things into our account, we must acknowledge that we cannot examine too closely, or scrutinize too minutely, the causes of his failure in the Russian campaign."

It appears, then, that these causes may be classed under two general heads, *viz.* those which proceeded from the nature of the country which he invaded, and the characteristic qualities of its inhabitants; and those which originated from the peculiar character of the invader.

In the first place, the constitution of the Russian army, and the character of the Russian soldiers, contributed in no small degree to the fate of Bonaparte. The Russians, from their infancy, are most devoutedly attached to their emperor, and to their nobility. Philosophers may ridicule the idea, or disbelieve the assertion, that the common people of Russia are attached to those who act towards them, in too many instances, as tyrants. But history is conversant with facts, not with theories and speculations; and the fact is, that the Russian common people, even before they enter the army, are most devoutly attached to their emperor and nobility. This attachment becomes still more strong and influencing when they enter the army:—they then regard themselves, in a more special manner, as entirely at the service of their sovereign; and look upon it as the highest honour which can befall them, to suffer any privation or misery, or even death itself, at his command, and for his sake.

fake. Military difcipline, with the troops of moft other nations, is a habit acquired late in life, irkfome and abhorrent to former habits, and broken through whenever it can be done with fafety. But it is far otherwife with the Ruffian foldier: he knows no habits; he has no feeling or fentiments incompatible with the ftricteft military difcipline: on the contrary, all his other habits, feelings, and fentiments, work to the accomplifhment of the fame end: all ferve and contribute to render him an excellent foldier, fo far as ftrictnefs of difcipline is concerned. Knowing no difgrace fo great as difobedience to the orders of his officers, and efpecially to the commands or even wifhes of his fovereign, he never ftirs from his poft till he is exprefsly directed fo to do: the idea of flight never enters his mind. But his fteadinefs is not merely paffive; endowed with great bodily ftrength, and with a robuftnefs of conftitution fuperior to every fatigue or privation, he wearies out his more fkilful and experienced opponent, by whom he may be outmanœuvred or flain, but cannot be forced to fly.

Hence Bonaparte never met with more obftinate refiftance than he did from the Ruffians at the battle of Eylau: his troops were weary with flaughter, but ftill they could not defeat the Ruffians; and had the French emperor been a man who could be taught mortifying or difagreeable truths by experience, after his firft campaign againft the Ruffians, on the borders of their own country, he never would have attempted to conquer them, in the very heart of their empire, and in the midft of a Ruffian winter.

In the fecond place, the character of the Ruffian generals contributed not a little to the defeat of Bonaparte: his avowed object in the invafion of Ruffia, was to compel the emperor Alexander to adhere to the continental fyftem, that was, to forbid all trade between Ruffia and England; but this would have been the ruin of the Ruffian nobility, whofe incomes were almoft exclufively derived from this commerce. Bonaparte, therefore, was making war upon them, and they muft have regarded his invafion as peculiarly directed againft them. This feeling would contribute to render them faithful and fteady to the caufe of their country, and at the fame time ftimulate them to put forth all their activity and talents in the conteft. Befides, the Ruffian nobility partake with the common people in that phyfical attachment to the foil and inftitutions of their country, which excites their hatred moft ftrongly againft all invaders. Hence they were above the influence of Bonaparte's promifes and bribes.

In the third place, the plan of the campaign which the Ruffian government had laid down, contributed very effentially to the overthrow of Bonaparte's hopes and projects. This plan was, on every occafion, where they could oppofe Bonaparte, there to oppofe him, but never in fuch a manner as might bring on a general action, or an action that could be decifive againft themfelves. Thus, the farther he advanced the weaker he became; and after every engagement, though he apparently fucceeded in driving back the enemy, the real ftate of his affairs was rendered worfe: he was led further from his refources, deeper into the heart of a country utterly incapable of fupporting a large army, and more completely furrounded by the Ruffians.

In the fourth place, the character of the Ruffian peafantry contributed much to the defeat of Bonaparte: thefe could not be feduced from their allegiance; they uniformly, and to a man, refufed to hold any communication with the enemy: while Mofcow was in the hands of the French, they brought no goods in for fale: they regarded it as a polluted city, and would have fhuddered to have entered it. To thefe caufes muft be added the firmnefs of Alexander; and the nature and climate of the country.

The next clafs of caufes which contributed to Bonaparte's difcomfiture and ultimate ruin, muft be fought for in his own peculiar character, in which the moft predominant and influential is his obftinacy. Accuftomed to fee all his plans fucceed, all his predictions, however extravagant, verified, he could ill-brook difappointment: he could not even fuffer himfelf to admit that he had acted an imprudent and rafh part, and preferred perfeverance in error, to the acknowledgment and rectification of it. His obftinacy operated in giving rife to the invafion of Ruffia, as well as influencing his conduct during that invafion. He probably pufhed forward into Ruffia notwithftanding the loffes which he fuftained, and afterwards continued in Mofcow till winter had rendered his retreat almoft impoffible, under expectation, or at leaft the hope, that Alexander would be induced to propofe terms of conciliation. This certainly influenced his conduct; "but," fays a good writer, "whoever has ftudied the character of obftinate people, muft be convinced that at laft, when their obftinacy is got to its greateft height, they perfevere in the courfe which muft infallibly conduct to ruin, without even the moft groundlefs hope of extricating themfelves. The impulfe in this ftate of mental diforder, for fo it may be denominated, is blind, and almoft mechanical. So it probably was with Bonaparte, when he determined to remain fo long at Mofcow."

How different were the affairs of this man at the commencement of 1812, from what they were at the fame period in the following year. At the *former* every thing was profperous, except perhaps the war in the peninfula; and that, it was generally believed, he could, at any time, turn in his favour by fending a larger army there. Ruffia, though uneafy under the operation of the hard terms to which fhe fubmitted at the peace of Tilfit, would fcarcely have ventured to commence a new war; while the fubferviency of Pruffia to his will, his abfolute command of her fortreffes which are on the confines of Ruffia, and his alliance and family connexion with Auftria, feemed to promife him the eafy conqueft of Ruffia whenever he fhould think proper to attack her. At the latter period he no longer appeared as the invincible conqueror, but as the fallen general, who had fled to his capital with unexampled celerity, to avoid the indignation of the fragments of that army which had been facrificed to the madnefs of his ambition. He who had always detailed victories the moft fplendid, who had, in direct language, held himfelf out as fuperior to all the cafualties of war, was now obliged, in his own bulletins, to confefs that his army was broken, and it was returning towards France defeated and haraffed by the Tartars of Afia.

Thus changed in power, in feelings, and in profpects, the Parifians faw their emperor at the beginning of the year 1813, and they, as well as Europe in general, were extremely anxious for the meeting of the legiflative body, in order that they might be able to develope his future plans. At this meeting, on the 14th of February, he declared it to be his determination ftill to carry on the war, and to facrifice nothing for the fake of obtaining peace: "The French dynafty," fays he, "reigns, and will reign, in Spain. I am fatisfied with all my allies; I will abandon none of them; I will maintain the integrity of their ftates; the Ruffians fhall return to their frightful climate. I defire peace, but I will never make any but an honourable peace, and one conformable to the interefts and grandeur of my empire." The whole tone of his addrefs was warlike, and he immediately fet on foot a new confcription, which, by means of his gens

d'armes,

d'armes, he readily carried into effect, at leaft to a certain point. By means of uncommon exertion and activity, joined to the moft tyrannical defpotifm, he fucceeded, by the beginning of April, in collecting a large force on the banks of the Elbe, though that force was of a very different defcription from the veteran army which he had loft in Ruffia. His cavalry and artillery were particularly inferior; and it was on thefe two branches, efpecially the artillery, that the French ufed to depend for their victories; it is even faid that, in confequence of his having loft upwards of 1000 pieces of cannon in Ruffia, he was under the neceffity of fupplying his army, in a great meafure, with cannon from the fhips at Antwerp, which were, of courfe, of a defcription by no means fuited for military purpofes.

Before Bonaparte left Paris, to take the command of his army, he judged it expedient to fettle the form of a provifional government during his abfence: he had fo narrowly efcaped deftruction in his Ruffian campaign, at a time when he had taken no meafures refpecting the government of France while the king of Rome was a minor, that he refolved to guard againft all accidents for the future. Accordingly his emprefs was regularly declared regent during his abfence; and the king of Rome was nominated, in a more folemn manner than heretofore, his fucceffor. It is probable that the appointment of the emprefs as regent had other objects in view; Bonaparte knew well the temper and difpofition of the Parifians; he knew that the beft mode of drawing off their thoughts and fpeculations from the difafters that had occurred, or might occur, was by keeping up the fplendour, buftle, and pageantry, of a court; and this could be done with the beft effect by invefting his emprefs with the name and dignity of regent. Having thus taken what he conceived to be all due precautions, and fent on before him immenfe bodies of troops, he clofed the feffion of the legiflative body in a fpeech full of his ufual confidence and haughtinefs, in which he led them and the French nation to expect, that on the banks of the Elbe he fhould regain all thofe laurels which he had loft amidft the fnows of Ruffia.

Having thus detailed the preparations which Bonaparte made for the commencement of what has been denominated the German campaign, we muft notice briefly the preparations of thofe powers who were to oppofe him. Alexander, at the head of his army, advanced with great rapidity into the north of Germany. As foon as he croffed his own boundaries into thofe of Pruffia, he ordered a declaration to be iffued, explanatory of his motives and views. The Ruffian emperor was every where hailed as a deliverer, and upon his entrance into Berlin he was received with the utmoft enthufiafm by all ranks of the people, and in the end Pruffia became a noble ally to the northern potentate. She was indeed deftined to act a confpicuous part in avenging her own wrongs and thofe of Germany. Her armies were put on the beft footing. Blucher, who had already immortalized himfelf by his conduct, had a leading and extenfive command; and it feems to have been the wife policy of the continental fovereigns, in this laft ftruggle for their independence, to felect thofe generals againft whom Bonaparte had difplayed the greateft rancour; they thus fecured themfelves from treachery, while they called forth all the talents of their commanders. Befides the regular army of Pruffia, the landwehr or militia were called out; all were anxious to be enrolled to co-operate in the deliverance and defence of their country.

In the mean time the Ruffian army continued to advance, and having liberated great part of Pruffia, directed their efforts towards the emancipation of Saxony. Count Wittgenftein, who commanded the Ruffian army, addreffed to the Saxons a moft noble and infpiriting proclamation, which, though it probably made a deep impreffion, did not, at the time, produce the confequences which the Ruffian general anticipated. The king of Saxony was with the French, and no fmall part of their country was occupied by thofe people, circumftances which naturally prevented many from joining the allies whofe wifhes were cordially with them; when, however, an opportunity did occur, it will be feen that the Saxons proved themfelves worthy of the name of Germans, and of their anceftors. A hope was now excited that Bernadotte, the crown prince of Sweden, and his numerous army, would be brought to act in favour of the allies; this expectation was confiderably ftrengthened by treaties which were concluded between the courts of Sweden, Ruffia, and Great Britain. By thefe treaties, the army under the crown prince was immediately to be employed in the common caufe, and in return for his acceffion of force, Great Britain, befides granting a fubfidy to Sweden, agreed to give up to her the ifland of Guadaloupe, and to guarantee the kingdom of Norway when it fhould be conquered from the Danes.

Thus it was known that early in the year 1813, Great Britain, Ruffia, Pruffia, and Sweden, were decidedly againft France. Hoftilities commenced, and in many parts the French were decidedly victorious; Hamburgh, and many other places in the north of Germany, fell into their hands. The firft great battle in which Bonaparte was himfelf engaged, was at Lutzen, on the 1ft of May; the Pruffians, having partially fucceeded in breaking into the fquares of the enemy, committed great carnage, and the conflict on all fides was moft defperate and fanguinary. For a confiderable time the allies were the affailants, but towards evening, Bonaparte called in that divifion of his army which was near Leipfic, and collecting all his referves, made a moft furious attack, for which the allies were not prepared; night however put an end to the combat. The allies remained mafters of the field that evening, but judged it prudent, early on the next day, to commence a retreat, in confequence of which Bonaparte claimed the victory in the battle of Lutzen. But it was not fuch a victory as he ufed formerly to boaft of; and on the 21ft of May another bloody battle was fought at Bautzen, which was ftill in favour of the French, and the allies again found it expedient to retreat. The lofs of the enemy in this obftinate battle was very fevere; though Bonaparte gained ground by it, he gained it at fuch an expence of men, and with fuch a conviction of the bravery and fkill of the allies, that he muft have been very unwilling to have obtained many fuch victories. But the moft alarming circumftance which occurred during the battle of Bautzen, was the defertion of a whole battalion of Wurtemburghers, as well as a body of Saxon troops, which muft have convinced Bonaparte how little dependence he could place on the German troops. The allies continued their retreat, and on the 24th of May their head quarters were within 18 leagues of Berlin. On the 4th of June, through the mediation of the emperor of Auftria, an armiftice was agreed on, which was to continue till the 20th of July. It was a matter of great difficulty to determine on which fide the advantage of this armiftice lay; both parties were probably defirous of it, and as the emperor of Auftria preffed it moft earneftly, each party readily agreed to it, in the hope of gaining his affiftance, or avoiding his hoftility. It was, however, extremely unpopular throughout Germany, and efpecially in the Pruffian ftates; fo much fo, that the king deemed it neceffary to iffue a proclamation, in which he declared that the armiftice had not been fought for by the allied powers, and that they would only ufe it to re-inforce their armies, and attack the common enemy, at its expiration, with more vigour. Bonaparte, on his own part, complained that the terms of the armiftice were not faithfully kept by the allies; this complaint, which was well founded, arofe from a circumftance which augured fatally for his future fuccefs; for the landwehr of Pruffia, and even all the inhabitants who could procure any kind of arms, notwithftanding the fufpenfion of hoftilities, were continually attacking and haraffing the French, and in many cafes they captured their fupplies of ftores and provifions, and rendered precarious and difficult their communication with France.

It was foon evident that the armiftice would not lead to peace, each party was exerting itfelf to the utmoft to recruit and re-inforce their army. The emperor Alexander ordered frefh troops to be brought acrofs the Viftula, and in a fhort time the re-inforcements that joined the allied army from Ruffia alone, amounted to 75,000 men. The king of Pruffia contributed as much to the common caufe as the exhaufted ftate of his country, and of its finances, would allow. Bonaparte was equally active; oppofite to the main army of the allies he had collected nearly 130,000 men.

The armiftice was prolonged till the middle of Auguft, during which a congrefs was held at Prague, at which little or nothing was done, or perhaps even attempted. The mediation of the emperor of Auftria was of no avail; the terms which he propofed as juft and equitable to all parties, were peremptorily rejected by Bonaparte. No alternative, therefore, he faid, remained for him to adopt, but to unite his forces with thofe of the emperor of Ruffia and the king of Pruffia. Still, however, he, as well as they, were going to fight, not for the purpofes of ambition or conqueft, but folely for the attainment of a juft, honourable, and lafting peace. As foon as this could be brought about, they would moft cheerfully lay down their arms; but till it was brought about, they would continue united in hoftilities, and exert themfelves to the utmoft.

Ruffia, Auftria, Pruffia, and Sweden, were now to try their ftrength againft France; the jealoufies and felfifhnefs of the allied fovereigns, which had rendered former coalitions of no value, were abforbed in the deep and awful conviction that now they were fighting for their own exiftence; befides, in the former contefts, they were averfe from, or indifferent to, the caufe of their fovereign; now they were cordial and zealous in their co-operation. The allied powers alfo very wifely made ufe of other weapons than thofe of warfare; the moft eloquent and popular writers in Germany were employed to roufe the people, to hold out Bonaparte as no longer formidable; as having been conquered; but ftill as the implacable enemy of the happinefs and peace of Germany, as the common deftroyer of the liberty of the fovereign and the peafant.

Befides the crown prince of Sweden, another Frenchman entered into the lifts againft Bonaparte, *viz.* general Moreau, who, after he had been liberated by him, had gone over to America, where, in peace, quiet, and retirement, he had fpent fome years of his life. It is not known by what particular motives he was induced to enter again into public fervice; but it appears that the emperor Alexander, as foon as he found that war with Bonaparte was inevitable, fent over a confidential perfon to America, with whom general Moreau returned to Europe. He joined the allied army foon after the congrefs at the Prague was diffolved.

On the 17th of Auguft hoftilities recommenced, and a moft fevere battle was, a few days after, fought at Drefden, in which, after a terrible flaughter on both fides, the French fucceeded in repulfing the allied armies, but the moft difaftrous event in the courfe of this battle was, the death of Moreau, who had both his legs fhot off by a cannon ball.

Bonaparte reprefented the battle of Drefden as moft decidedly favourable to him, and he probably confidered the lofs and difcomfiture of the allies as much more ferious than they really were, as in order to intercept their retreat into Bohemia, he difpatched Vandamme, one of his generals, with a force which it would have been madnefs to have fent againft them, had he not believed their army to have been not only much reduced in numbers, but retreating in great diforder. In the attack, Vandamme, and fix other generals, were taken prifoners, befides 10,000 men, 60 pieces of artillery, and 6 ftandards.

In Silefia the campaign opened on the 18th of Auguft, the allies in this quarter moving on towards Drefden; they firft attacked and defeated a corps under marfhal Ney, which induced Bonaparte to fet out to re-inforce his general; the French having now greatly the fuperiority, general Blucher retreated, and took up a ftrong pofition behind the Katzbach. The plan of the allies being to diftract and divide Bonaparte's forces, they fell farther back, while the grand army from Bohemia, as we have feen, marched on to Drefden, and drew off Bonaparte to that quarter. On the 25th and 26th the French advanced againft Blucher, but on the latter of thofe days the Pruffian general attacked them. The battle was fought near the Katzbach, and from that takes its name; in it Blucher and the Pruffians proved their determination to avenge the difgrace which their country had fo long fuffered by having been under the tyranny of France. They fought with the moft unparalleled bravery, and gained a complete victory. Among the fruits of their fpoil were 18,000 prifoners, 103 pieces of cannon, and 280 ammunition waggons. In another quarter the crown prince was likewife victorious over the French; and in a fecond battle, *viz.* that of Juterbock, it was calculated that the vanquifhed French had loft from 16 to 18,000 men, more than 50 pieces of cannon, and 400 ammunition waggons.

After thefe defeats the fituation of Bonaparte became more critical, yet he ftill remained at Drefden, and continued there till the 7th of October, when he quitted it, taking with him the royal family of Saxony. Hitherto the allies of Bonaparte had remained more faithful to him than might have been expected, but about this period the king of Bavaria deferted him, and concluded a treaty of alliance and concert with Auftria, by which 35,000 Bavarian troops were immediately to co-operate with thofe of Auftria.

On the 14th of October Bonaparte collected his whole force in and round Leipfic, and on the 18th the famous battle of Leipfic was fought, in the courfe of which two Saxon battalions, and two Weftphalian regiments of huffars, quitted the ranks of the enemy and joined the allies; the artillery which they brought over with them, they immediately turned againft the French, and the crown prince headed the men in a charge againft their former oppreffors. In the battle of this day the French loft at leaft 50,000 men in killed, wounded, and prifoners, befides 65 pieces of artillery. Bonaparte now left Leipfic, and in two hours afterwards the allied armies entered that town.

The retreat of Bonaparte from Leipfic with the wreck of his army, to the amount of 80,000 men, was fcarcely furpaffed in diforder and mifery by his retreat from Mofcow. As foon as he reached the Rhine he left his army, haftened to Paris, and on his arrival, another confcription of 300,000 men was ordered, but France was now too much exhaufted to anfwer the demand; the Ruffian and German campaigns had almoft entirely ftript her of the efficient military population; befides, there was wanting that enthufiafm which had,

twenty

twenty years before, been characteristic of the country, so that it was almost deaf to this new demand.

In the mean time the mighty edifice which Bonaparte had erected out of the ruins of the independence and liberties of the continent, and which had been cemented by the blood of hundreds of thousands, was falling to pieces; the victory of Leipsic, by freeing the minds of the princes of Germany from all apprehensions of his power, proved how eager they were to resume their legitimate character and authority. Wurtemburgh deserted him, and made her peace with the allies; and the confederation of the Rhine was dissolved; so that, to use his own words, no sovereigns remained attached to him except the king of Denmark and the king of Naples.

Holland, which had long groaned under French tyranny, early in the month of November broke her shackles, dismissed the constituted authorities, established a provisional form of government, and by the assistance of Great Britain she was at length enabled to hold up her head as a free and independent nation, recalling her hereditary prince, and investing him with new powers, and higher titles than the members of the house of Orange had formerly exercised and claimed. Rather before this period the allied troops, under the command of the crown prince, had entered Hanover, which they liberated from French thraldom, much to the satisfaction of the inhabitants, and by the end of November almost all the strong places between the Elbe and the Rhine were in possession of the allies, and such as were not, were closely invested. On the 1st of December they issued their famous proclamation, which, from its justice and moderation, probably did them as much, or more, service, than any of their victories. "The allied powers," say they, "do not make war upon France, but against that preponderance which, to the misfortune of Europe and of France, the emperor Napoleon has too long exercised beyond the limits of his empire.

"Victory has conducted the allied armies to the banks of the Rhine. The first use which their imperial and royal majesties have made of victory, has been to offer peace to his majesty the emperor of the French. An attitude strengthened by the accession of all the sovereigns and princes of Germany has had no influence on the conditions of that peace. These conditions are founded on the independence of the French empire, as well as on the independence of the other states of Europe. The views of the powers are just in their object, generous and liberal in their application, giving security to all, honourable to each.

"The allied sovereigns desire that France may be great, powerful, and happy; because the French power, in a state of greatness and strength, is one of the foundations of the social edifice of Europe. They wish that France may be happy, that French commerce may revive, that the arts (those blessings of peace) may again flourish, because a great people can only be tranquil in proportion as it is happy. The allied powers confirm to the French empire an extent of territory which France, under her kings, never knew; because a valiant nation does not fall from its rank, by having in its turn experienced reverses in an obstinate and sanguinary contest, in which it has fought with its accustomed bravery."

Immediately after the issuing of this declaration, the allies having completed their arrangements, crossed the Rhine for the purpose of invading France; as, however, the strong fortresses near Mentz rendered the passage in this place rather difficult, they preferred passing through Switzerland, by the inhabitants of which country they were hailed as friends, and afforded every assistance.

The allied army entered Switzerland on the 20th of December, penetrated to Zurich and Berne, and crossed the Rhine at Basle without firing a shot, and before the end of the year detachments of the allies made their way to Langres, in Champagne, which was about 100 miles within the old French frontier. The year 1814 opened with an invasion of France, not only by the allies in the east and north, but on the south by lord Wellington, while the Austrian forces in Italy, aided by the naval exertions of Great Britain, and by detachments from our garrisons in the Mediterranean, completely kept the viceroy in check. Every event tended to shew that Bonaparte's power was tottering, and he must have been convinced that he had only one thing to depend on, *viz.* his own personal prowess. He accordingly left Paris on the 25th of January to take command of the armies, and on the 1st of February a great battle was fought between him and marshal Blucher, which was decided in favour of the allies, and the retreat of Napoleon from his positions about Brienne, with the loss of 4000 prisoners, was the consequence of his defeat.

On the 7th of February the position and town of Troyes was taken possession of by the allies; this town was thought to be of great importance to their cause, on account of its resources, its population, and of the number of roads leading to it from different parts of France. At this period negociations were carrying on at Chatillon-sur Seine for the purpose of effecting a peace, during which the allies had gained several conquests over the French armies. Bonaparte had been beaten in several engagements with Blucher and prince Schwartzenburg, whose armies, at the close of February, were at Troyes and Chalons, while he himself was at Rheims. On the 19th of March the negociations were to terminate, and on that day Napoleon refused the terms that were offered him, though by those terms he would have continued at the head of the French, with dominions as extensive and powerful as had ever been enjoyed by any of the former monarchs.

On the day that the conferences at Chatillon were terminated, the French army moved upon Arcis, behind which the corps commanded by field marshal count Wrede was posted.

The allies, under Schwartzenburg, concentrated on the Aube, near Pougy and Arcis, and a general attack was made by the allies on the 20th, in which the enemy was defeated at all points, with great loss, and Arcis was taken.

At this juncture, Napoleon formed the desperate and extraordinary plan of passing between the two armies of the allies, and of striking at their communications with the Rhine, intending at the same time to liberate the garrison of Metz. For this purpose he moved by Chalons on Vitry and St. Dizier, his head-quarters being, on the 22d, at Obcomte, between the two latter places. This bold and characteristic resolution was formed in the expectation that it would alarm the allies so much for their own safety, as not only to draw them away from Paris, but actually entangle them in the very difficulties with the prospect of which he endeavoured to terrify them;—this movement was fortunately defeated by their resolution of marching upon Paris, a resolution which was—considering the time and circumstances in which it was taken—one of the grandest that ever entered into the mind of man, and does the highest honour to the names of the emperor Alexander and prince Schwartzenburg;—to which of those great men the idea suggested itself, perhaps they themselves are not conscious; but it is certain they both eagerly adopted it, and must equally share in the glory of that great enterprise in which they risked themselves and their armies for the deliverance of mankind.

For two days after this determination and change of march, Bonaparte was employed, as he hoped, in anticipating the allies, and in preparing the fprings in which his victims were to be caught; but no enemy came—no intelligence arrived: from Paris he heard nothing—from the reft of France little; and a hoftile army of 200,000 men muft be, he knew, at no great diftance from him, but he could not guefs where. Over Winzingerode, who was in his vicinity, near St. Dizier, with a fmall force, he obtained fome, and claimed greater advantages; but thefe fucceffes left him as much in the dark as ever.

He was convinced that this corps was but the advanced guard of the Ruffians; and when one of his generals reported it was not fo, and that the main body of the allies had fufpended their retreat, he himfelf thought the news almoft too good to be believed, and calculated that the time thus loft would enable him to perfect his plans for their deftruction.

In thefe circumftances, it was Napoleon who thought his enemies undone; and far from confidering them as having refumed the offenfive, he faw in their movement of concentration only a meafure of retreat. He announced it triumphantly to the emprefs in letters written with his own hand: thefe letters were intercepted by the allies. They were then certain of having deceived him, and they urged with great precipitation their movement againft the capital.

Of the march upon Paris either he never thought, or his arrogance haftily rejected the idea; but at laft, after a lofs of three days, he felt that it became abfolutely neceffary to afcertain the enemy's pofition, and he accordingly haftened by forced marches through Bar-fur-Aube towards Troyes. A junction was, however, formed by prince Schwartzenburg and marfhal Blucher; and the whole allied force marched upon Paris, with a rapidity that infured its fuccefs. The defences which had been raifed in the neighbourhood of that city were attacked late in the day of the 30th March, and the enemy, under the command of Marmont, made a moft determined refiftance; but the allies were almoft every where fuccefsful.

At the moment of thefe decifive advantages, a flag of truce was fent from Marmont, intimating a defire to receive any propofitions that it might have been intended to make to him by a flag of truce, which had previoufly been refufed admittance. An armiftice was alfo propofed by him for two hours; to obtain which, he confented to abandon every pofition he occupied without the barriers of Paris.

On the 31ft in the morning, the allies entered Paris. In the evening, Caulincourt came from Bonaparte to the emperor of Ruffia, offering to accede to the terms of peace which the allies had offered at Chatillon. The emperor gave no other anfwer, than that the time was paft for treating with Bonaparte as fovereign of France.

Immediately, by the defire of the emperor of Ruffia, the fenate met, and chofe a provifional government, confifting of Talleyrand and four other members. At their fecond fitting, they declared that Bonaparte had forfeited his right to the empire, and that his dynafty was at an end. They alfo refolved, that the fenate and legiflative bodies fhould form fundamental parts of the new conftitution.

On the 1ft of April the provifional government inftalled itfelf, and of this Bonaparte feems to have been aware; and on the 2d he collected at Corbeil, Fontainebleau, and the neighbourhood, at leaft 20,000 men, whom he reviewed and thus addreffed: "The enemy is in Paris. I do not wifh to fpeak of the inhabitants of that city, but a horde of emigrants, whom I had recalled, reftored, and laden with perfonal favours, have offered their fervices to the emperor of Ruffia, and have hoifted the white cockade. The tri-coloured cockade we won in our revolution; we have ennobled it in our empire. It has fhared too many triumphs with us ever to be abandoned. If Paris is to be retaken at the point of the bayonet, I will march at your head. May I reckon upon you? Am I right? Will you ever abandon this national cockade?" "Never, never; vive l'empereur! vive Napoleon! à Paris!" was the anfwer of the whole line of troops.

The marfhals prefent at this fcene were far from partaking or encouraging this enthufiafm: they that fame night affembled in the palace, and when admitted to Napoleon's prefence, with many references to their former fervices, and profeffions of duty and affection, acquainted him that all was loft; that at moft he could collect but 56,000 men, and that for them he had not two days provifions; but the only means of faving any thing from this great fhipwreck, was to abdicate in favour of the king of Rome.

Bonaparte, for the firft time in his exiftence, heard a remonftrance in filence, and ultimately affented to the propofal. On the 3d, marfhal Ney put into his hands the Paris journals, in which the déchéance, pronounced by the fenate the day before, was publifhed; and, in the name of his brethren, on the public parade, gave him that advice fo terrible to the ear of a tyrant, "Sire, il faut abdiquer; c'eft le vœu de la France et de l'armée." Napoleon, thunderftruck, retired into the palace. On the 4th he figned his own abdication, and addreffed an order of the day to his army, in which, after contrafting forcibly and juftly the former fervility and prefent tergiverfation of the fenate, he intimates, that if he is the only obftacle to peace, he is ready to make the laft facrifice for France; and that he has fent Ney, Caulincourt, and Macdonald to Paris, "pour entamer des negociations." Thefe negociations, which had for their object the continuance of Bonaparte's power under the cloak of a regency, to be adminiftered by his wife, in her own name, or that of her fon, happily failed. Others then enfued, in which the difcuffions were not queftions of policy, power, or government, but of pounds, fhillings, and pence; and on the 11th of April was figned the famous treaty, by which Bonaparte abandoned for himfelf and his family the thrones of half the world, and ftipulated only for the empty titles of his better days, a retreat in the obfcureft corner of his late dominions, and a penfion of 2,000,000 of livres *per annum* from the civil lift of Lewis XVIII.; and, finally, on the 12th he figned the formal inftrument of his abdication on the part of himfelf and his dynafty.

Such was the termination of this difaftrous revolution; and in a very few weeks after the depofition of Bonaparte, Lewis XVIII. returned, and took a quiet poffeffion of the throne of his fathers. Of the ftability of the new government we prefume to offer no conjectures. Of the character of the prefent fovereign much might be faid in applaufe; of the new conftitution, at prefent, we know but little: and into what it may ultimately fettle it is difficult to fpeak. Many recent occurrences in different parts of Europe have mortified the friends to human happinefs; the fociety of Jefuits, always inimical to the interefts of mankind, has been re-eftablifhed. The Inquifition, which Bonaparte abolifhed, and which it was imagined could, in this enlightened age, never more rear its horrid head, has been revived in Spain, to the everlafting difgrace of the prince who ordered its eftablifhment, and to the people who permitted it. When we read the decree, that "the tribunal of the Inquifition is abolifhed, as derogatory to the fovereign power, and to civil authority," we did anticipate a new era, even for Spain, and are mortified, beyond the power of language to defcribe, to find that feveral of the beft and moft virtuous inhabitants of that country are now fuffering under a tribunal which curfed the world for fo many centuries, which, for the boldnefs and wickednefs of the original conception, the immenfe extent of its power, the audacity of its attempts, the greatnefs of its fuccefs, and the length of its domination, finds no parallel in the records of the world.

We might, as a conclufion to this article, take fome notice of the principal actors and fufferers in the revolution which we have been contemplating, but we are afraid of transgreffing the allowed limits. Befides, in our alphabetical arrangement, we have already noticed feveral of the moft diftinguifhed of thefe perfons; fee particularly the articles Bailly, Condorcet, Marat, Mirabeau, Lewis XVI., Malesherbes, and Neckar, and to fome others, according to the plan of our work, diftinct articles will hereafter be given. (See Roland-Turgot, Robespierre, Vergniaud, &c.) Of Danton, who took a very active part in fome of the bloodieft fcenes in Paris, and who fell a victim to the axe which he had fharpened for others, we may obferve, that he was educated to the law, and in the progrefs of the revolution was fucceffively the affociate of Mirabeau, Marat, and Robefpierre. He organized fome of the chief tumults and maffacres in the city, particularly that of the 10th of Auguft. After the fall of royalty, he obtained an appointment of adminiftrator of juftice, a ftation in which money poured on him from all fides, and which was fpeedily diftributed by him to procure adherents and reward atrocities. He was deeply involved in the horrid maffacres of September, and, when fubfequently called to account for the diftribution of the money charged for fecret fervice, he declared, that "in a revolution there could be no reckoning in detail." It was Danton who prevented the national affembly from leaving Paris on the approach of the Pruffians. He was brought to the guillotine by Robefpierre, who was his rival, but his inferior in every thing but cunning and hypocrify. For this article, we refer, as authorities, chiefly to the volumes of the New Annual Regifter.

Revolution *of America*. See America, and United States.

Revolution *in Poland*. See Poland.

Revolution, in *Geometry*. The motion of any figure quite round a fixed line, as an axis, is called the revolution of that figure; and the figure fo moving is faid to revolve.

Thus, a right-angled triangle, revolving round one of its legs, as an axis, generates, by that revolution, a *cone;* which fee.

Revolution, in *Aftronomy*, denotes the period of a ftar, planet, comet, or other phenomenon; or its courfe from any point of its orbit, till it return to the fame.

The planets have a twofold revolution. The one about their own axis, ufually called their *diurnal* rotation, which conftitutes what we call their *day*.

The other about the fun, called their *annual* revolution or *period*, conftituting their year. See *Motion of the* Planets.

REVOLUTUM Folium, in *Botany*. See Leaf.

REUS, in *Geography*, a town of Spain, in Catalonia, where feveral merchants at Barcelona have agents for the purchafe of wine, brandy, and fruit, with which the country abounds.

REUSS, a river that rifes from a lake in Mount St. Gothard, croffes the canton of Uri, paffes through the lake of the Four Cantons to Lucerne, and then taking a northerly courfe, runs into the Rhine, two miles N. of Klingnan, in the county of Baden.

REUSSEN, a princely county of Saxony, divided into feveral branches, which take their names from the towns which they poffefs, all fituated in the Vogtland.

REUSSIN, or Redzen, a town of the duchy of Warfaw; 40 miles S.S.W. of Pofen.

REUT, a town of Bavaria, in the bifhopric of Bamberg; three miles E. of Forcheim.—Alfo, a river of European Turkey, which runs into the Dniefter, near Uftia, in the province of Moldavia.

REUTELE, in *Ichthyology*, a name ufed by fome for the *umbla minor*, or red charr, a fifh common in the lakes of Germany, and of the northern parts of England and Wales. The name is originally German.

REUTLINGEN, in *Geography*, a town of Wurtemberg, on a fmall river, which runs into the Neckar. It has only one parochial church, together with one hofpital, an orphan-houfe, and a grammar-fchool. The magiftrates and burghers are Lutherans. Near it was difcovered, in 1716, a fulphurous fpring; 32 miles W. of Ulm. N. lat. 48° 30'. E. long. 9° 8'.

REUTO, a town of Saxony, in the Vogtland; 6 miles W.S.W. of Plauen.

REUTTE, a town of Germany, in the county of Bregentz; 9 miles S.S.E. of Bregentz.

REUTTEN, or Reita, a town of the Tyrolefe, on the borders of Swabia; 32 miles N.W. of Infpruck.

REVULSION, in *Medicine*, the derivation of the fluids of the body, from a part in which they are morbidly accumulated, to another part, whether near or diftant.

This principle is much acted upon in the practice of medicine, although confiderably lefs than by the advocates of the humoral pathology. Thefe practitioners carried the principle fo far as to make their evacuations generally at fome point oppofite and diftant to the part difeafed; thus, to relieve the head, they would bleed from the foot, or from the hæmorrhoidal veins about the anus; and if a pleurify occurred in the left fide, they would open a vein in the right arm; and fo forth. Thefe were mere hypothetical refinements, and have fallen into difufe in this country. Much of the practice of medicine, however, in acute and in fome local chronic difeafes, hinges upon the principle of revulfion. Thus, for the removal of inflammatory congeftion in any internal organ, as in the lungs or brain, a counter-inflammation is excited externally in the fkin of a contiguous part, by applying a blifter, or a ftimulating liniment, to the furface of the cheft, to the neck, or on the fcalp: and thus by bringing an afflux of the fluids to thefe external parts, which are of lefs importance to life, the congeftion in the veffels of the more important and vital organs is diminifhed, and the inflammation cured. In a fimilar manner, the derivation of the fluids to the inteftines by cathartic medicines, to the kidnies by diuretics, and to the fkin by fudorifics, tends to diminifh the congeftion of the circulating fyftem at large, and confequently of particular organs. Blood-letting, whether by directly opening the veins and fmall arteries, or by the application of leeches, or of cupping-glaffes after fcarification, likewife operates upon the principle of revulfion.

Confiderable errors, however, have been committed, efpecially by the humoral pathologifts, by carrying this doctrine too far. For in their attempts to procure evacuations of the fluids, efpecially from the fkin, they have employed heat, and ammoniacal, fpirituous, and other ftimulant medicines, which, by the excitement and irritation which they

 occafioned

occasioned in the nervous and vascular system, produced much more inflammatory action, than the revulsion, resulting from the evacuation, could possibly subdue. See Humoral *Pathology*.

Revulsion is also used for a spontaneous turn or reflux of humours in the body. Sudden diseases are occasioned by great revulsions of humours, which fall all at once on certain parts.

REWAH, in *Geography*, a town of Hindoostan, in the country of Allahabad; 57 miles S.S.W. of Allahabad. N. lat. 24° 35′. E. long. 81° 36′.

REWARDS. Military rewards, among the Athenians, consisted sometimes in crowns presented to those that had merited them; on which their names and noble actions were inscribed. Some had leave granted them to erect pillars or statues in honour of some god, with inscriptions setting forth their victories. This was a favour that was seldom granted; Cimon indeed was honoured with it, but Themistocles could never obtain the like. Another honour conferred at Athens on the valiant, was to have their arms placed in the citadel, and to be called *Cecropidæ*, or citizens of the true old blood. Others were presented with a πανοπλια, or complete suit of armour. Songs of triumph were honorary compliments paid to some. The children of those who were killed in battle were maintained at the public expence, till they came to maturity; at which time they were presented before the assembly of the Athenian people with a complete suit of armour, one of the public ministers proclaiming before them, "that hitherto, in remembrance of their fathers' merits, the commonwealth had educated these young men, but now dismissed them so armed, to go forth and thank their country by imitating their fathers' examples."

Solon made a farther provision for the parents of those that died in the wars, it being extremely reasonable that they should be maintained at the public expence, who had lost their children, the comfort and support of their declining age, in the service of the public.

As for those who were any wise disabled, they had an allowance from the public towards their maintenance. Potter, vol. ii.

Triumphal honours were reckoned among the military rewards which the ancients voted to their best generals. Fabius Maximus, Paul Emilius, Camillus, and the Scipios, were satisfied with this recompence for their services. With respect to old infirm soldiers, who were invalided, they were provided for by receiving, each, a lot of ground, which they cultivated and improved. Lands, thus appropriated, formed part of the republican or national domains, or were divided amongst them in the conquered countries.

The Roman officer was rewarded for his services, or for particular acts of bravery, in three ways: 1st. By marks of honour or distinction, which consisted of two sorts, *viz.* of that which was merely ornamental to their own persons, or limited to the investiture for life; and of that which may be called *rememorative*, such as statues, &c. The latter descended to their posterity, and gave their families a certain rank in the republic. 2dly. By pensions or allowances. And 3dly. By a grant of lands which exceeded the lots given to private soldiers.

The French, who got possession of the country which was formerly occupied by the Gauls, had, at first, no other method of recompensing their generals than by giving them a certain proportion of land. This grant did not exceed their natural lives, and sometimes it was limited to the time they remained in the service.

These usages insensibly changed, and by degrees it became customary for the children of such men as had received grants of national territory, to continue to enjoy them; upon condition, however, that the actual possessors of such lands should be liable to military service. Hence the origin of fiefs in France, and the consequent appellation of *milice des fieffés*, or militia, composed of men who held their lands on condition of bearing arms when called upon. The French armies were for many years constituted in this manner; and the custom of rendering military service in consideration of land tenure, only ceased under Charles VII.

In process of time, those lands which had been originally bestowed upon men of military merit, descended to their children, and were gradually lost in the aggregate lots of inheritable property. Other means were consequently to be resorted to by the state, in order to satisfy the just claims of deserving officers and soldiers. The French, therefore, returned to the ancient custom of the Romans, and rewarded those, who distinguished themselves in war, by honorary marks of distinction.

Honorary rewards and compensations for service were not confined to individual officers and soldiers. Whole corps were frequently distinguished in the same manner. When several corps acted together, and one amongst them gave signal proofs of gallantry and good conduct, that one frequently took precedence of the others in rank, or was selected by the sovereign to be his personal guard. Sometimes, indeed, the king placed himself at the head of such a corps on the day of battle, thereby testifying his approbation of their conduct, and giving a proof of his confidence in their bravery.

It is now usual, in most countries, to confer marks of distinction on those corps that have formed part of any army that has signalized itself. Thus the kettle-drums, under the appellation of *nacaires*, were given to some regiments, as proofs of their having behaved gallantly on trying occasions.

The military order of St. Louis, which was created by Louis XIV. in 1693, and that of Maria Theresa, as well as many other orders in different countries, were only instituted for the purpose of rewarding military merit. The establishment of hospitals for invalids, such as Chelsea, &c. owes its origin and continuance to the same just sense of what is due to deserving officers and soldiers. Hence, likewise, our invalid companies and retired lists.

Philip Augustus, king of France, first formed the design of building a college for soldiers who had been rendered infirm, or were grown old in the service. Louis, surnamed the Great, not only adopted the idea, but completed the plan in a grand and magnificent style. Charles II. on his restoration to the crown of Great Britain, established Chelsea, and James II. added considerable improvements to this royal institution. During the present reign, military merit has been rewarded by titles and pensions; but, what is still more creditable to the government, and reflects honour upon his royal highness the duke of York (for his co-operation with those who originally suggested the idea) old and meritorious soldiers are taught to expect a secure retreat in the decline of life; and every rank is provided for according to the claims and services of individuals.

Rewards, in a *legal sense*. There are rewards given in many cases, by statute, for the apprehending of criminals, and bringing them to justice; as a reward of 40*l.* to those who apprehend robbers on the highway, and prosecute them to conviction, by 4 & 5 W. & M. c. 8, to be paid to them (or, if killed in the endeavour to take them, their executors) by the sheriff of the county; to which the statute 8 Geo. II. c. 16. superadds 10*l.* to be paid by the hundred indemnified by such taking. Also the like reward of 40*l.* for apprehending

hending and profecuting of burglars. Stat. 5 Ann. cap. 31. See LARCENY.

The fame reward for apprehending of money-coiners, or clippers, &c. 6 & 7 W. III. And the like reward for the apprehenfion of thief-takers, not profecuting felons; and of perfons refifting the officers of the cuftoms, by force of arms, &c. 6 Geo. I. cap. 20. 22. See DISCOVERY *of Accomplices*.

REWARI, in *Geography*, a circar of Hindooftan, in the Subah of Delhi, between Ballogiftan on the N. and Mewat on the S.—Alfo, a town of Hindooftan, and capital of the forementioned circar; 48 miles S.W. of Delhi. N. lat. 28° 13′. E. long. 36° 52′.

REWEY, a term among *Clothiers*, fignifying cloth unevenly wrought, or full of *rewes*. 43 Eliz. cap. 10.

REX AMARORIS, in *Botany*, Rumph. Amboin. v. 2. 129. t. 41, a fhrub or tree, fo called on account of its fupreme bitternefs, as well as its reputed medical virtues. The natives of Ternate, according to Rumphius, efteem it a perfect panacea. In cholera, pleurify, and various kinds of fevers, it is particularly recommended. The fruit, of a compreffed heart-like fhape, and coriaceous texture, is cut into fmall pieces, and chewed with Betle-nut. Its exceffive bitternefs caufes a naufea, fuppofed to be beneficial to the patient. Linnæus cites the above chapter of Rumphius, in his *Syft. Veg.* under *Ophioxylon*, but incorrectly, *Rex amoris*. A fpecimen of the true plant is found in his herbarium, but it has no affinity to *Ophioxylon*. We have a more perfect fpecimen, gathered in the ifland of Honimoa, by the late Mr. Chriftopher Smith, in March 1797, by which the plant feems to belong to *Pentandria Digynia*. The *leaves* are elliptical, entire, a fpan long, alternate, on long ftalks; their under fides filky, efpecially when young; with one ftout midrib, and many ftraight parallel tranfverfe veins. *Flowers* very fmall, in numerous, fimple, filky, axillary, folitary clufters. *Calyx* minute, apparently of only two acute leaves. *Petals* five, larger than the calyx, uniform, oblong, concave, at length reflexed. *Stamens* awl-fhaped, fimple. *Anthers* roundifh, fimple, two-lobed. *Germen* fuperior, obovate, compreffed, cloven at the top. Styles none. *Stigmas* obtufe, converging. The ripe *fruit* we have not feen. Rumphius fays it confifts of two cells, with a white feed, like that of a cucumber, in each. The foliage bears confiderable refemblance to fome of the *Contortæ*, but there is no character of that tribe in the fructification; as far, at leaft, as we can difcern. The *germen* and *ftigmas* are not unlike thofe of *Ulmus*. The half-formed *fruit* proves intenfely bitter, as foon as it is put into the mouth.

REX *Minftrellorum*, king of the minftrels. About the year 1330, the minftrels of Paris formed themfelves into a company, and obtained a charter. The police frequently repreffed their licentioufnefs, and regulated their conduct. Philip Auguftus banifhed them the firft year of his reign; but they were recalled by his fucceffors, and united under the general name of *meneftraudie*, minftrelfy; having a chief appointed over them who was called king of the minftrels. Lewis IX. exempted them from a tariff or toll at the entrance into Paris, on condition that they would fing a fong, and make their monkies dance to the tollman, perhaps to prove their title to fuch indulgence; and hence arofe the well-known proverb, " Payer en gambades et en monnoïe de finge."

The affociated minftrels inhabited a particular ftreet, to which they gave the name, which it ftill retains, of St. Julien des Meneftriers. It was here that the public were provided with muficians for weddings, and parties of pleafure; but as a greater number of them ufually attended on fuch occafions than were ordered, and all expected to be paid the fame price, William de Germont, provoft of Paris, in 1331 prohibited the jongleurs and jonglereffes from going to thofe who required their performance in greater numbers than had been ftipulated, upon a fevere penalty. In 1395 their libertinifm and immoralities again incurred the cenfure of government, by which it was ftrictly enjoined that they fhould henceforth, neither in public nor private, fpeak, act, or fing any thing that was indecorous or unfit for modeft eyes and ears, upon pain of two months' imprifonment, and living on bread and water.

In the reign of Charles VI. they feem to have relinquifhed the juggling art, and to have confined themfelves more particularly to the practice of mufic. It was about this time that treble and bafe rebecs, or viols with three ftrings, began to be in ufe, either to play in octaves to each other, or perhaps in a coarfe kind of counterpoint, of which the laws were now forming: on this occafion the minftrels affumed the title of players on high and low inftruments (joueurs des inftrumens tant haut comme bas), which feems to imply treble and bafe inftruments. And the charter under this denomination was confirmed in 1401.

REX *Mullorum*, in *Ichthyology*, a name given by fome authors to a fpecies of mullet, diftinguifhed from all the others by its having a prominent belly, and having no beards under the mouth.

REX *Sacrificulus*, the *King-prieft*, in *Mythology*, was inftituted, after the expulfion of the kings of Rome, to perpetuate the memory, according to Dionyfius Halicarnaffeus, of the great fervices fome of their kings had done to Rome. A law was made, that the pontiffs and augurs fhould choofe one of the oldeft to have the charge of divine worfhip; but for fear that the name of king fhould again create jealoufy, it was appointed at the fame time, that the rex facrificulus fhould be fubject to the high prieft. He had likewife the name of " Rex Sacrorum," and his wife that of " Regina Sacrorum." The firft perfon that was chofen under this appellation, after the expulfion of the Tarquins, was Maxim Papirius, of Patrician extraction.

REX, in *Ornithology*, a fpecies of *Turdus*; which fee.

REX *Vulturum*. See VULTUR *Papa*.

REY, in *Geography*, a town of Perfia, in the province of Irak, called *Rae*; which fee.

REY, a river of England, in Wiltfhire, which runs into the Thames, near Cricklade.

REY *Ifle*, a fmall ifland in the bay of Panama. N. lat. 8°. W. long. 79° 46′.

REY-*Grafs*, in *Agriculture*, a hardy early fort of grafs, much efteemed among farmers. See LOLIUM *Perenne*, and RAY-*Grafs*.

REYES, in *Geography*, a town of New Navarre; 64 miles S. of Cafa Grande.—Alfo, a town of Peru, in the Audience of Lima; 12 miles N. of Tarma.

REYES, *Los*, a town of South America, in the province of St. Martha; 140 miles W. of Maracaybo. N. lat. 10° 15′. W. long. 73° 30′.—Alfo, a fmall ifland near the coaft of Patagonia, at the entrance of Port Defire. S. lat. 47° 50′.

REYES *Magos*, a town of Brazil; 40 miles N. of Spiritu Santo.

REYES *le Yapey*, *Los*, a town of South America, in the province of Buenos Ayres; 180 miles S.E. of Corrientes.

REYGADA, a town of Portugal, in the province of Beira; fix miles N.N.E. of Pinhel.

REYGATE, or REIGATE, a borough and market-town in the weft half hundred of Reygate, and county of Surrey, England, is fituated at the diftance of 19 miles eaft from Guilford,

Guilford, and 21 ſouth by weſt from London. It is of great antiquity, and is mentioned in the General Survey by the appellation Cherchefelle, or Cherchfield; but it ſoon afterwards became generally known by that of Ridge-gate, ſince corrupted into Reygate. The manor was formerly veſted in the crown; and, previous to the Conqueſt, conſtituted part of the property ſettled by king Edward the Confeſſor on his queen, Edith. King William Rufus granted it to the illuſtrious family of the Warrens, earls of Warren and Surrey, ſeveral of whom obtained conſiderable privileges for the town. John, earl of Warren, in the reign of Edward II. procured for the inhabitants the charter, under which they now enjoy the right of holding a weekly market on Tueſday. Another, held on the firſt Wedneſday of every month, was eſtabliſhed by charter from Charles II.; it was for many years diſuſed, but has lately been revived.

Reygate is a borough by preſcription only. The government is veſted in a bailiff, conſtable, tythingman, ale-taſter, fleſh-taſter, fiſh-taſter, and leather-ſeller, with a conſtable for the foreign diviſion, and a tythingman for each of the forenſic ſubdiviſions, or tythings. This town originally ſent members to parliament in the twenty-third year of Edward I. The electors are the freeholders of meſſuages or burgage tenements within the precincts of the borough, and the bailiff is the returning officer.

The pariſh of Reygate is divided into two capital precincts, which provide ſeparately for the maintenance of their reſpective poor, *viz.* the borough and the forenſec, or foreign, the latter including all that portion of the pariſh not comprehended in the former. Within the precinct of the borough ſtands the town itſelf, which is ſeated at the baſe of a ſteep hill of chalk. The buildings are principally diſpoſed in two long and ſpacious ſtreets, of which one, called the High-ſtreet, runs in a direction from weſt to eaſt; and the other, called Bell-ſtreet, in a direction from north to ſouth. The pariſh church, placed at a ſmall diſtance from the town, although not diſtinguiſhed for its antiquity or elegance of its architecture, is nevertheleſs one of the beſt eccleſiaſtical ſtructures in the county. It is divided into a nave, two ſide aiſles, and a chancel, with an embattled tower at the weſt end. The nave and chancel are ſeparated from the aiſles by ſeven pointed arches; five of which, on each ſide, are in the nave and two in the chancel; thoſe of the former being ſupported by pillars, alternately round and octagonal; and thoſe of the latter by cluſtered pillars of a more elegant form. Every portion of the interior is crowded with monuments and inſcriptions to the memory of the Thurlands, of Thurland Caſtle in Nottinghamſhire, the Jameſes of Reygate, the Skinners of the ſame place, and others of leſs note. In a vault under the chancel, conſtructed by William, firſt baron Howard of Effingham, are depoſited many leaden coffins, containing the remains of the founder, and of ſeveral of his deſcendants, earls of Nottingham, and their families. The moſt remarkable of theſe is that inſcribed to the memory of Charles Howard, earl of Nottingham, who commanded the Britiſh fleet in the memorable conteſt with the Spaniſh armada, A. D. 1588.

The old market-houſe ſtood at the weſt end of the town, but it having gone to decay, the preſent houſe was erected, by ſir Joſeph Jekyll, near the ſcite of the ancient priory, which formed one of the terminations of Bell-ſtreet. This religious eſtabliſhment was founded by William de Warren, earl of Surrey, and Iſabel his wife, about the year 1230. The inmates conſiſted of a prior, and a few canons regular, of the order of St. Auguſtine, whoſe clear annual revenue, at the time of the diſſolution, amounted to 68*l.* 16*s.* 8*d.* After that event the ſcite of the priory, with its appurtenances, was granted by king Henry VIII. to William, lord Howard, in exchange for the rectory of Tottenham in Middleſex. The other religious buildings here were, two chapels, dedicated to St. Lawrence, and to Thomas à Becket, and the hoſpital of the Holy Croſs, which ſeems to have been connected with the priory.

On a conſiderable eminence to the north of the town, ſtood the ancient caſtle of Reygate, the foundation and hiſtory of which are little known. Moſt of the very ſlender accounts of it which have reached our times, aſcribe its origin to ſome of the more ancient earls of Warren and Surrey, but others aſſert, that the original ſtructure was of much earlier date, and the work of our Saxon anceſtors. Indeed, if the inhabitants of this part of the country were ſo active and ſucceſsful in repelling the Daniſh invaders, as to give riſe to the proverb attributed to them by Camden, "The Vale of Holmeſdale,—never wonne, ne never ſhall," it ſeems not improbable, conſidering alſo the importance and advantage of the ſituation, that their leaders had a fortreſs here ſufficient for the purpoſes of rendezvous and ſecurity. It is certain that there was a fortreſs at Reygate, of conſiderable note, under the earls of Warren, and which ſeems to have been for many years one, at leaſt, of the capital ſeats of their barony. William, earl of Warren, who poſſeſſed it in king John's time, is the firſt of the family ſpoken of by Dugdale as the proprietor of it; and he acknowledges his title to be derived from his earlieſt anceſtors. This earl, in the conteſt between that king and his barons, was one of the neutral lords who joined in the confederacy againſt the king with reluctance, and who, at the great council at Runnymead, were inclined to favour him; and by whoſe advice the great charter was eventually ſigned by him. This dubious policy of the earl occaſioned the loſs of his caſtle at Reygate, which, ſoon after the landing of Louis the dauphin, was ſurrendered to him. When it was firſt diſmantled is uncertain, but it is mentioned as having been decayed and ruinous in the reign of James I. Even then, and for ſome time after, it muſt have been capable of defence, as in the time of the civil wars, A. D. 1648, the committee of the houſe of commons were ordered "to take care of it, and to put it into ſuch a condition, that no uſe might be made to the endangering the peace of the kingdom." What the immediate reſult of theſe orders was we are not informed, but it was probably demoliſhed ſoon afterwards, though a ſmall part of the walls was ſtanding within the laſt forty years. Now, however, every veſtige of theſe is gone; but the vallum and ditch are ſtill nearly entire on the ſouth and weſt ſides; and in the centre of the area is a deſcent, by a flight of ſteps, to a paſſage 235 feet long, which leads into a cave 123 long, 13 wide, and 11 high. This cave is conjectured to have ſerved the double purpoſe of a repoſitory for military ſtores, and a place of cuſtody for priſoners: it might alſo be a place of ſafety in times of public commotion.

The park at Reygate is ſituated to the ſouth of the town. It contains about 150 acres, and appears, by a ſurvey made in 1622, to have been then well ſtored with timber trees, and with veniſon. It was diſparked within twenty years from that period, and now retains few of its former characteriſtics, except the name. At Eaſt-Beechworth, to the weſtward of Reygate, is a ſeat of the late Hon. William Henry Bouverie, which was built by ſir Ralph Freeman in the reign of James I.; and near it is Wonham, a manſion belonging to viſcount Templetown: Gatton, to the northward, about two miles, affords an example of nominal borough repreſentation, ſcarcely a houſe being left ſtanding within its limits. In this pariſh, at a place called Battle-

Battle-bridge, tradition affirms that a great ſlaughter of the Danes took place. Aubrey ſtates that a caſtle exiſted here, but no traces of ſuch a building can now be diſcovered. See Gatton.

Merſtham, to the eaſt of Gatton, is noted for its ſtone quarries, which were anciently held in ſuch high repute that the crown deemed it expedient to keep them in its own poſſeſſion. A great part of Windſor caſtle, and the magnificent chapel of Henry VII. at Weſtminſter, were conſtructed with ſtone from theſe quarries. The quality which renders it peculiarly valuable, is its effectual reſiſtance againſt fire, whence it is denominated fire-ſtone. It is very ſoft when firſt raiſed from the quarry, but becomes indurated by expoſure to the atmoſphere. A rail-road has been formed here to facilitate the conveyance of ſtone and lime from the quarries to the metropolis. Merſtham-place is a ſpacious manſion belonging to Hylton Jolliffe, eſq. In the pariſh of Newdigate, about ſix miles ſouth-weſt from Reygate, is Ewood, a manſion lately erected by the preſent duke of Norfolk. The houſe ſtands on the brow of an eminence, and is ſurrounded by a park containing about 600 acres of ground, and ornamented with a fine lake, covering ſixty acres. At Nutfield, as well as at Reygate, are ſome fuller's-earth pits, which yield excellent earth. Hiſtory and Antiquities of the County of Surrey, by the Rev. Owen Manning; edited, with additions, by W. Bray, eſq. F.S.A.; vol. i. folio. Beauties of England and Wales, 8vo. vol. xiv. by I. Shorbel.

REYHER, Samuel, in *Biography*, an eminent German mathematician, was born at Schleuſingen, in Saxony, in the year 1635. He received the early part of his education under his father, and then purſued his mathematical ſtudies at the univerſity of Leipſic. He next went to Leyden, and ſtudied the algebra of Vieta under the celebrated James Golius, with whom he contracted an intimate friendſhip. On his return to Leipſic, he obtained ſo high a reputation in teaching the mathematics, that he was nominated preceptor to the young prince of Gotha, the eldeſt ſon of the duke of Saxe-Gotha. In 1665 he accepted an invitation to fill the mathematical chair at the univerſity of Kiel, and having firſt paid a viſit to Leyden, he was there admitted to the degree of doctor in civil law. In a few years afterwards he was appointed profeſſor extraordinary of civil law, in 1683 profeſſor in ordinary of the Inſtitutes, and in 1692 profeſſor of the code of Juſtinian. He died in 1714, in the 80th year of his age. He tranſlated the works of Euclid into the German language, illuſtrating the geometrical with algebraical demonſtrations, wherever they would admit of it; and he publiſhed, among many other works, a learned work entitled "Matheſis Biblica;" and a very curious "Diſſertation concerning the Inſcription on the Croſs of Jeſus Chriſt, and the Hour of his Crucifixion." Moreri.

REYN, Jan de, or Rheni, called alſo *Lang Jan*, was an artiſt of very conſiderable merit, a diſciple, and ſkilful imitator, of Vandyke; to whom he was ſo much attached that he followed him to London, and remained ſome time with him. He was born at Dunkirk in 1610; and he ſo effectually benefited by the inſtructions of Vandyke, that his pictures are frequently ſold for thoſe of that maſter. But as he, in general, painted hiſtory more than portrait, he has a freer line in compoſition, though not ſo correct a one as his maſter. His works are ſcarce, though he lived to the age of 68, but their apparent ſcarcity is poſſibly owing to ſo many of them being imputed to Vandyke. Among the works which are indiſputably his, are mentioned the Baptiſm of Totila, which is in a church at Dunkirk; and a grand altar-piece in the pariſh church of St. Martin, at Bergues, repreſenting Herodias bringing the head of St. John to Herod. He died in 1678.

REYNA, Cassiodorus de, celebrated for being the firſt tranſlator of the whole bible into the Spaniſh language, and on this account he is noticed, though we have no particulars concerning his life. To his tranſlation he introduced notes explanatory and critical. The place where this verſion was printed is not mentioned in the title-page, though, from ſome typographical marks, it may be aſcertained pretty correctly that it was at Baſil; and as the author was probably a Proteſtant, he thought proper to conceal his name, that it might not prevent his work from being received among the Spaniſh Catholics, and it has only his initials R. C. to a Latin preface, recommending it to the kings, princes, and nobles of Europe, and particularly of the Roman empire. The date is 1569, and it is entitled "La Biblia, Que Es, Los Sacros Libros Del Vieio y Nuevo Teſtamento. Tranſladada en Eſpagnol." The firſt edition of this verſion is now very ſcarce. Moreri.

REYNEAU, Charles René, an eminent French mathematician, was born at Briſſac, in the province of Anjou, in the year 1656. At the age of twenty, he took up his reſidence in the houſe belonging to the congregation of the Oratory at Paris, without any intention of entering into the community. His object was to enjoy the advantages in ſtudy which that celebrated order afforded for improvement in literature. In a ſhort time, however, a change took place in his mind, and he became a member of the houſe. He became ſtrongly attached to the ſcience of geometry, and in 1683 he was appointed to a mathematical profeſſorſhip at Angers: this poſt he retained 22 years with extraordinary reputation. In this ſituation he undertook to reduce into one body, for the uſe of his ſcholars, the principal theories ſcattered through the writings of Deſcartes, Leibnitz, Bernouilli, the Leipſic Acts, the Memoirs of the Paris Academy of Sciences, and other works. The fruit of this undertaking, entitled "The Analyſis demonſtrated, &c." he publiſhed at Paris in the year 1708, in two vols. 4to. He aſſumed this title for his work becauſe it contained demonſtrations of ſeveral methods of analyſis which had not been demonſtrated by the authors of them, or, at leaſt, not with ſufficient perſpicuity and exactneſs. By ſupplying what was left undone by other perſons, he rendered ſo ſignal a ſervice to mathematical ſtudents, that it became a maxim, at leaſt in France, that to follow father Reyneau was the beſt way to make much progreſs in mathematics. Hence he was eſteemed the Euclid of the ſublime geometry. His great work was reprinted in 1738. In the year 1714 he drew up an elementary work on the ſubject, under the title of "The Science of Calculation, &c." which was moſt favourably received. This came out in one volume, and he had prepared materials for a ſecond, which did not make its appearance till after the author's death. In 1716 the Royal Academy of Sciences at Paris admitted ſome new members, under the deſignation of "free aſſociates:" father Reyneau was of that number, and he frequently aſſiſted at their meetings. He died in 1723, at the age of 72, regretted as well for his many virtues, as for profound and extenſive learning. The firſt men in France for talents deemed it an honour to count Reyneau among their friends. In this number was father Malebranche, of whom Reyneau was a zealous diſciple. He left behind him a treatiſe on "Logic, or the Art of Reaſoning," which was publiſhed in 1745. Moreri.

REYNEL, in *Geography*, a town of France, in the department of the Upper Marne; 12 miles W. of Bourmont.

REYNESBURCH, a town of Holland; three miles N.W. of Leyden.

REYNOLDS, *Sir* JOSHUA, *Knt.*, in *Biography*, was the fon of the Rev. Samuel Reynolds, rector of Plympton, near Plymouth, in Devonfhire, and was born there, on July 16, 1723; the tenth of eleven children, five of whom died in their infancy. He was, for fome time, inftructed in the claffics by his father, and was intended for the practice of phyfic; but he began, at a very early age, to difplay an inclination for the art in which he fubfequently made fo diftinguifhed a figure. At eight years of age he made himfelf fo far mafter of perfpective, as to draw his father's bookcafe according to rule, and, encouraged by his affectionate parent, amufed himfelf by copying prints that he found in books, and particularly thofe in Jacob Kat's emblems. From thefe early labours the tranfition was eafy to the attempt at drawing likeneffes of his friends, and in thefe he obtained tolerable fuccefs. Richardfon's Treatife on Painting was then put into his hands, and, according to his own report, he was, by that work, ftimulated to the greateft degree of enthufiafm for the art of painting, and led to regard its profeffors, particularly Raphael, as among the greateft and moft illuftrious of men, either in ancient or modern time. After he had fpent fome time practifing in the neighbouring country, his parents were induced, by the advice of a Mr. Cranch, to fend him to London, as the place beft calculated to improve talents fuch as he had fo decidedly exhibited; and accordingly, in October 1741, he firft vifited the capital, and was immediately placed with Mr. Hudfon, the moft renowned portrait painter of that time, in order to acquire the firft rudiments of this art.

Whatever was the caufe, whether, as it is faid, Hudfon became jealous of the ability of his pupil, or, as is equally probable, the pupil became difgufted with the want of tafte exhibited by his mafter, in little more than two years they difagreed, and young Reynolds returned to his father, and again employed himfelf in painting his friends. Many of thefe early productions of his pencil are ftill to be feen in the town and neighbourhood of Plymouth, and fome of them poffefs very confiderable merit, and indicate his future prowefs. One of them, particularly, of a boy reading in reflected light, 30 years afterwards, excited furprize in his own mind, and an expreffion of regret that, in fo many years, he fhould have made fo little progrefs in his profeffion. He is faid to have lamented having paffed this period of his life in the way he had done; moft probably, however, that regret alludes to his abfence from London, where he would moft undoubtedly have feen more of the art, and learnt more of its practice, than elfewhere. But perhaps it was a fortunate occurrence that he was removed to a ftation where he had to rely upon his own emotions, unbiaffed by the grofs and barbarous tafte which then prevailed; fince, guided by thofe emotions, he attempted to follow the dictates of nature, untrammelled by the pedantry of amateurs, and the low ignorance of the greater part of the profeffors of the day.

Finding his practice increafing, he took a houfe at Plymouth Dock, and there became known to the family of Mount Edgecumbe, by whom he was warmly patronized, and recommended to captain (afterwards lord) Keppel, who carried him to Italy in 1749; and it would appear, from a letter of his to lord Mount Edgecumbe, written when he was in Rome, that that noble lord defrayed the expence of his refidence there. The courfe of his ftudies during the three years that he fpent there, is not precifely known. He made fome few copies of figures and heads from the works of Raphael, but that does not appear to have been a favourite mode of ftudy with him, for in one of his lectures he has faid, "the man of true genius, inftead of fpending all his hours, as many artifts do while they are at Rome, in meafuring ftatues, and copying pictures, foon begins to think for himfelf, and endeavours to do fomething like what he fees. I confider general copying as a delufive kind of induftry; the ftudent fatisfies himfelf with the appearance of doing fomething; he falls into the danger of imitating without felecting, and of labouring without any determinate object: as it requires no effort of the mind, he fleeps over his work; and thofe powers of invention and difpofition, which ought particularly to be called out and put in action, lie torpid, and lofe their energy for want of exercife. How incapable of producing any thing of their own, thofe are, who have fpent moft of their time in copying, is an obfervation well known to all who are converfant in our art." That he reflected deeply on the great works of the ancient and modern mafters is evident, both from his pictures and writings; though the tafte with which he fubfequently applied the knowledge he had acquired, proves the originality of his mind, and the extent of his genius.

Mr. Reynolds returned through Paris to England in October 1752, and after a fhort time fpent at his native place, to recruit his health, which had fomewhat fuffered by the journey, he fixed his fettled refidence in the metropolis; taking a houfe in St. Martin's-lane. He there painted, as his firft effay, a head, from an Italian youth he had brought over with him, (Giufeppe Marchi). He dreffed it in a rich turban, and its execution excited fo much attention, that his old mafter, Hudfon, was induced to go to fee it, and carefully watched its progrefs: when, upon feeing at length no trace of his own manner left, and unable, or unwilling, to find any other merit in it, he exclaimed, "why Reynolds, you don't paint fo well as you did when you left England!" Notwithftanding this augural declaration, the pupil became the fuperior favourite with the public; and Hudfon retiring, left him without a competitor.

In 1753, or 4, he took a large houfe in Newport-ftreet, where he refided for eight or nine years, and there he painted a whole length portrait of his friend commodore Keppel walking on the fea-fhore, which drew upon him univerfal admiration, and fixed him completely in the public efteem. At this time his price was ten guineas for a head; in 1755 he raifed it to twelve; and in 1758 to twenty guineas; and he afterwards, by degrees, advanced it to fifty; at which it remained till he declined practice; the price of a half length, during the latter period, being 100, and for a whole length 200 guineas.

To fay that he was univerfally regarded as being at the head of the profeffion of portrait painting at the time adverted to, cannot indeed be confidered as any great praife, fuch was its degraded condition; though Hudfon had certainly advanced above his immediate predeceffors. Reynolds however, deferved much more, for he united to a dignified characteriftic refemblance of the head, an endlefs variety of fpirited and graceful attitudes, picturefque back-grounds, novel and ftriking effects of light and fhade, with a voluptuous richnefs and harmony of colour, which certainly had never before been feen united to fo many other qualities in that branch of the art. It muft not, however, be underftood, that his performances at that time poffeffed thofe excellencies to the degree in which we find them in his latter works; for he was one of the few, whofe efforts ended but with his life; who has been heard to fay, that he never began a picture without a determination to make it his beft; and whofe unceafing progrefs almoft juftified the maxim he was fo fond of repeating continually, "that nothing is denied to well directed induftry." Befides his uncommon

affiduity,

affiduity, which was apparent to all, little information remains to us of the precife method of ftudy by which fuch extraordinary excellence was attained, except what may be collected from the following extract, made from fome papers left by him, and intended perhaps for infertion in another difcourfe; in which, as his biographer obferves, he fpeaks of his merits and defects with fingular modefty and candour. "Not having the advantage of an early academical education, I never had that facility of drawing the naked figure which an artift ought to have. It appeared to me too late when I went to Italy, and began to feel my deficiencies, to endeavour to acquire that readinefs of invention which I obferved others to poffefs. I confoled myfelf, however, by remarking, that thofe ready inventors are extremely apt to acquiefce in imperfection, and that if I had not their facility, I fhould, for this very reafon, be more likely to avoid the defect which too often accompanied it,—a trite and common-place invention. How difficult it is for the artift who poffeffes this facility to guard againft careleffnefs and common-place, is well known; and in a kindred art, Metaftafio is an eminent inftance, who always complained of the great difficulty he found in obtaining correctnefs, in confequence of his having been in his youth an *improvifatore*. Having this defect conftantly in my mind, I never was contented with common-place attitudes or inventions of any kind. I confidered myfelf as playing a great game; and inftead of faving money, I laid it out fafter than I got it, in purchafing the beft examples of the art that could be procured; for I even borrowed money for this purpofe. The poffeffing portraits by Titian, Vandyke, Rembrandt, &c. I confidered as the beft kind of wealth. By ftudying carefully the works of great mafters, this advantage is obtained: we find that certain niceties of expreffion are capable of being executed, which otherwife we might fuppofe beyond the reach of art. This gives us a confidence in ourfelves, and we are thus incited to endeavour at not only the fame happinefs of execution, but alfo at other congenial excellencies. Study, indeed, confifts in learning to fee nature, and may be called the art of ufing other men's minds. By this kind of contemplation and exercife, we are taught to think in their way, and fometimes to attain their excellence. Thus, for inftance, if I had never feen any of the works of Correggio, I fhould never, perhaps, have remarked in nature the expreffion which I find in one of his pieces: or if I had remarked it, I might have thought it too difficult, or perhaps impoffible, to be executed.

"My fuccefs and continual improvement in my art (if I may be allowed that expreffion), may be afcribed, in good meafure, to a principle which I will boldly recommend to imitation; I mean a principle of honefty, which in this, as in all other inftances, is, according to the vulgar proverb, certainly the beft policy. I always endeavoured to do my beft. Great or vulgar, good fubjects or bad, all had nature; by the exact reprefentation of which, or even by the endeavour to give fuch a reprefentation, the painter cannot but improve in his art.

"My principal labour was employed on the whole together, and I was never weary of changing and trying different modes and effects. I had always fome fcheme in my mind, and a perpetual defire to advance. By conftantly endeavouring to do my beft, I acquired a power of doing that with fpontaneous felicity, which at firft was the effort of my whole mind, and my reward was three-fold; the fatisfaction refulting from acting upon this juft principle, improvement in my art, and the pleafure derived from a conftant purfuit after excellence.

"I was always willing to believe that my uncertainty of proceeding in my works, that is, my never being fure of my hand, and my frequent alterations, arofe from a refined tafte, which could not acquiefce in any thing fhort of a high degree of excellence. I had not an opportunity of being early initiated in the principles of colouring; no man, indeed, could teach me. If I have never been fettled with refpect to colouring, let it at the fame time be remembered, that my unfteadinefs in this refpect proceeded from an inordinate defire to poffefs every kind of excellence that I faw in the works of others: without confidering that there are in colouring, as in ftyle, excellencies which are incompatible with each other: however, this purfuit, or any fimilar one, prevents the artift from being tired of his art. We all know how often thofe mafters who fought after colouring changed their manner, while others, merely from not feeing various modes, acquiefced all their lives in that in which they fet out. On the contrary, I tried every effect of colour; and by leaving out every colour in its turn, fhewed every colour that I could do without it. As I alternately left out every colour, I tried every new one; and often, as is well known, failed. The former practice, I am aware, may be compared by thofe whofe firft object is ridicule, to that of the poet mentioned in the Spectator, who in a poem of 24 books, contrived in each book to leave out a letter. But I was influenced by no fuch idle or foolifh affectation; my ficklenefs in the mode of colouring, arofe from an eager defire to attain the higheft excellence. This is the only merit I can affume to myfelf from my conduct in this refpect."

His affiduity and love of his profeffion left him little leifure for country excurfions. Occafionally, however, he fpent a few days at his villa on Richmond-hill, and vifited, at different times, the feats of fome of the noblemen and gentlemen of his acquaintance, from whence he was always glad to return to the practice of his profeffion, and the enjoyment of that intellectual fociety, of which, like his friend Johnfon, he juftly confidered London as the head-quarters. He, very foon after he became fettled, perceived the advantage which one confined to the laborious duties of an arduous profeffion might derive from the fociety of literary men. Finding how little time he could fpare from his profeffion, for the purpofe of acquiring general knowledge from books, he refolved to partake as much as poffible of the benefits which might be drawn from the converfation of the learned and ingenious men of his time. In confequence of this, and of his cheerful and convivial habits, his table, for above thirty years, exhibited an affemblage of all the talents of Great Britain and Ireland; there being, during that period, fcarcely a perfon in the three kingdoms diftinguifhed for his attainments in literature or the arts, or for his exertions at the bar, in the fenate, or the field, who was not occafionally found there.

Soon after the return of fir Jofhua from Italy, he became acquainted with Dr. Johnfon, to whofe fuperior talents he was always proud to acknowledge his obligations; and in the paper we have before-mentioned, had expreffed his fenfe of the benefit he had derived from his fociety. When fpeaking of the value of affociating either perfonally or by ftudy with the truly great, he adds, "May I prefume to introduce myfelf as an inftance of the truth of what I have remarked. Whatever merit the difcourfes which I have had the honour of delivering from this place may have, it may in great meafure be imputed to the education which I may be faid to have had under Dr. Johnfon. I do not mean to fay, though it certainly would be to the credit of thefe difcourfes, if I could fay it with truth, that he contributed

contributed even a ſingle ſentiment to them; but he qualified my mind to think juſtly. No man had, like him, the faculty of teaching inferior minds the art of thinking."—"The obſervations which he made on poetry, on life, and on every thing about us, I applied to one art; with what ſucceſs others muſt judge." The great leviathan of literature found in the mind of Reynolds a congenial purity and ſtrength, and became zealouſly attached to him; who, with ſuch a coadjutor, found but little difficulty in collecting around him a circle of the moſt able and uſeful members of ſociety. Many illuſtrious foreigners were perſonally intimate with him; and his friendſhip was ſought by individuals of the higheſt quality; who revered his genius as much as they reſpected the worth of his private character. From ſuch connections, his mind, rich in its own ſtores, received an acceſſion of moſt extenſive information, and an inexhauſtible treaſure for converſation. He had a mind ever open to acquire uſeful knowledge; a ſound and penetrating judgment to ſelect what he acquired, and great induſtry and application in rendering his acquirements uſeful.

The variety of talent he exhibited, and the conſequent eminence which he gained, qualified him to ſhare the honours of the firſt ſcientific inſtitutions. He was accordingly admitted to the Royal, the Antiquarian, and the Dilletanti Societies; and when the late lord North was inſtalled chancellor of the univerſity of Oxford, in July 1773, ſir Joſhua was admitted to the honorary degree of doctor in civil law. He had previouſly, in 1769, been elected to the preſidency of the Royal Academy, in the formation of which he had a principal ſhare, and had, upon the occaſion, been honoured by his majeſty with the rank of knighthood. To this inſtitution he was a moſt invaluable member, and repaid the honour and fame he acquired from his ſituation in it, by a zealous attention to its intereſts. Nor did the Academy derive leſs credit from the admirable works which he continued yearly to exhibit in it, conſiſting indeed chiefly of portraits, though he rarely ſuffered a ſeaſon to paſs in which he did not bring forwards one or more ſpecimens of his powers in hiſtory. From the year 1769, when, as we have ſaid, the academy was founded, till 1790, incluſive, it appears that he ſent no leſs than 244 pictures to the exhibition.

The taſk of reading lectures was no part of the preſcribed duty of his office: but impoſed voluntarily upon himſelf for the following reaſons, aſſigned by him in his fifteenth diſcourſe. "If prizes were to be given, it appeared not only proper, but almoſt indiſpenſably neceſſary, that ſomething ſhould be ſaid by the preſident on the delivery of thoſe prizes; and the preſident, for his own credit, would wiſh to ſay ſomething more than mere words of compliment: which, by being frequently repeated, would ſoon become flat and unintereſting; and by being uttered to many, would at laſt become a diſtinction to none. I thought, therefore, if I were to preface this compliment with ſome inſtructive obſervations on the art, when we crowned merit in the artiſts whom we rewarded, I might do ſomething to animate and guide them in their future attempts." To the exertions which this moſt judicious ſenſe of propriety ſtimulated him to make, he is indebted, principally, for his renown as an author. In the courſe of twenty-one years, *viz.* from 1769 to 1790, incluſive, he compoſed fifteen diſcourſes; replete with the ſoundeſt principles, and the moſt uſeful information concerning the art he practiſed, that ever have been given to the world. In which, though it muſt be acknowledged that there are ſome few points not ſufficiently explained, yet they are free from the affected rant of connoiſſeurſhip, and practically efficient to guide the young, whilſt it confirms the more advanced, in purſuit of the juſt objects of the art of painting, and the ſureſt means of obtaining ſucceſs. Beſides theſe, he wrote three papers for the Idler, in 1759; *viz.* Nos. 76, 79, and 82; in which is exhibited his original turn of thinking on the nature and properties of beauty and of art: and in 1783, his notes to Maſon's tranſlation of Du Freſnoy's poem on Painting, gave to the world many practical obſervations and explanations of the rules laid down in the text, which convey inſtruction of the moſt uſeful kind, and tend to ſhew how carefully, and how ſyſtematically, his mind was made up on the ſubject.

It has been conjectured, and widely diffuſed in opinion, that ſir Joſhua did not compoſe his lectures himſelf. In ſupport of what is due to him on that head, Mr. Northcote, who lived ſome years in his houſe, has ſaid in his memoirs, "At the period when it was expected he ſhould have compoſed them, I have heard him walking at intervals in his room till one or two o'clock in the morning, and I have on the following day, at an early hour, ſeen the papers on the ſubject of his art which had been written the preceding night. I have had the rude manuſcript from himſelf, in his own handwriting, in order to make a fair copy from it for him to read in public: I have ſeen the manuſcript alſo after it had been reviſed by Dr. Johnſon, who has ſometimes altered it to a wrong meaning, from his total ignorance of the ſubject and of art; but never, to my knowledge, ſaw the marks of Burke's pen in any of the manuſcripts.

"The biſhop of Rocheſter, alſo, who examined the writings of Mr. Burke ſince his death, and lately edited a part of them, informed a friend that he could diſcover no reaſon to think that Mr. Burke had the leaſt hand in the diſcourſes of Reynolds." And Burke himſelf, in a letter to Mr. Malone, after the publication of ſir Joſhua's life and works, ſays, "I have read over ſome part of the diſcourſes with an unuſual ſort of pleaſure, partly becauſe being faded a little in my memory, they have a ſort of appearance of novelty; partly by reviving recollections mixed with melancholy and ſatisfaction. The Flemiſh journal I had never ſeen before. You trace in that, every where, the ſpirit of the diſcourſes, ſupported by new examples. He is always the ſame man; the ſame philoſophical, the ſame artiſt-like critic, the ſame ſagacious obſerver, with the ſame minuteneſs, without the ſmalleſt degree of trifling." We may ſafely ſay, this is not the language of one who had himſelf contributed much to thoſe diſcourſes. And if neither Johnſon nor Burke wrote for Reynolds, to whom elſe among his contemporaries ſhall the praiſe due to thoſe invaluable compoſitions be given, if Reynolds is to be deprived of it!

It is much to be lamented, that the world was deprived of this great artiſt before he had put into execution a plan which his biographer, Mr. Malone, ſays appears, from ſome looſe papers, to have been revolved in his mind. "I have found," ſays that author, "among ſir Joſhua's papers, ſome detached and unconnected thoughts, written occaſionally, as hints for a diſcourſe, on a new and ſingular plan, which he ſeems to have intended as a hiſtory of his mind, ſo far as concerned his art; and of his progreſs, ſtudies, and practice; together with a view of the advantages he had enjoyed, and the diſadvantages he had laboured under, in the courſe that he had run: a ſcheme, from which, however liable it might be to the ridicule of wits and ſcoffers, (of which, he ſays, he was perfectly aware,) he conceived the ſtudents might derive ſome uſeful documents for the regulation of their own conduct and practice." Such a compoſition, from ſuch a man, written after he had ſpent a long life in ſucceſsful practice, with none to guide him; who had choſen a line of art for himſelf, ſtamped with originality; and in which he had to develope principles, and elucidate them by practice; and competent as he was to explain the operations of his own mind; could not fail of being interesting and useful in the highest degree. One of these detached ideas we have quoted above, and lament that any of them should be withheld from publication.

In 1781, during the summer, he made a tour through Holland and the Netherlands, with a view of examining critically the works of the celebrated masters of the Dutch and Flemish schools. An account of this journey, written by himself, containing much excellent criticism on the works of Rubens, Vandyke, Rembrandt, &c. in the churches and different collections at Antwerp, Brussels, Ghent, the Dusseldorf gallery, and at Amsterdam, was published after his death; it concludes with a masterly drawn character of Rubens.

In 1783, in consequence of the emperor's suppression of some religious houses, he again visited Flanders, purchased some pictures by Rubens, and devoted several more days to the contemplation and further investigation of the performances of that great man. On his return, he remarked that his own pictures wanted force and brilliancy, and appeared, by his subsequent practice, to have benefited by the observations he had made. This year, on the death of Ramsay, he was made principal painter in ordinary to his majesty, and continued so till his death.

For a very long period he had enjoyed an almost uninterrupted state of good health, except that in the year 1782 he was for a short time afflicted with a paralytic stroke. A few weeks, however, perfectly restored him, and he suffered no inconvenience from it afterwards. But in July 1789, whilst he was painting the portrait of lady Beauchamp, he found his sight so much affected, that it was with difficulty he could proceed with his work; and notwithstanding every assistance that could be procured, he was in a few months totally deprived of the use of his left eye. After some struggles, he determined, lest his remaining eye should also suffer, to paint no more: and though he was thus deprived of a constant employment and amusement, he retained his usual spirits, and partook of the society of his friends with apparently the same pleasure to which he had been accustomed; and was amused by reading, or hearing others read to him. In October 1791, however, his spirits began to fail him, and he became dejected, from an apprehension that an inflamed tumour, which took place over the eye that had perished, might occasion the destruction of the other also. Meanwhile he laboured under a more dangerous disease, which deprived him both of his spirits and his appetite. During this period of great affliction to all his friends, his malady was by many supposed to be imaginary, and it was erroneously conceived, that by exertion he might shake it off; for he was wholly unable to explain to the physicians the nature or seat of his disorder. It was only about a fortnight before his death that it was found to be in the liver; the inordinate growth of which, as it afterwards appeared, had incommoded all the functions of life. Of this disease, which he bore with great fortitude and patience, he died, after a confinement of three months, at his house in Leicester-square, on Thursday evening, February 23, 1792, at the age of 69.

In stature, sir Joshua Reynolds was rather under the middle size, of a florid complexion, roundish, blunt features, and a lively pleasing aspect; not corpulent, though somewhat inclined to it; and extremely active. With manners uncommonly polished and agreeable, he possessed a constant flow of spirits, which rendered him at all times a most desirable companion; always ready to be amused, and to contribute to the amusement of others, and anxious to receive information on every subject that presented itself: and though he had been deaf almost from the time of his return from Italy; yet, by the aid of an ear trumpet, he was enabled to partake of the conversation of his friends with great facility and convenience. On the 3d of March his remains were interred in the crypt of St. Paul's, near the tomb of sir Christopher Wren, with every honour that could be shewn to worth and genius by an enlightened nation; a great number of the most distinguished persons attending the funeral ceremony, and his pall being supported by three dukes, two marquisses, and five other noblemen.

In many respects, both as a man and a painter, sir Joshua Reynolds cannot be too much studied, praised, and imitated by every one who wishes to attain the like eminence. His incessant industry was never wearied into despondency by miscarriage, nor elated into neglect by success. Either in his painting-room, or wherever else he passed his time, his mind was devoted to the charms of his profession. All nature, and all art, was his academy, and his reflection was ever on the wing, comprehensive, vigorous, discriminating, and retentive. With taste to perceive all the varieties of the picturesque, judgment to select, and skill to combine what would serve his purpose, few have ever been empowered by nature to do more from the fund of his own genius: and none ever endeavoured more to take advantage of the labours of others. He made a splendid and useful collection, in which no expence was spared. His house was filled, to the remotest corners, with casts from the antique statues, pictures, drawings, and prints, by various masters of all the different schools. Those he looked upon as his library, at once objects of amusement, of study, and competition. After his death they were sold by auction, with his unclaimed and unfinished works, and, together, produced the sum of 16,947*l.* 7*s.* 6*d.* The substance of his whole property, accumulated entirely by his pencil, and left behind after a life in which he freely parted with his wealth, amounted to about 80,000*l.*

It remains to speak of his style as an artist, which is precisely that, denominated in his lectures the ornamental style; but which, beautiful and seducing as it undoubtedly is, cannot be recommended in so unreserved a degree as his industry both in study and practice: that which he characteristically terms his own uncertainty, both in design and in execution, operates too frequently and too powerfully against its entire adoption. In the higher attainments of the art, colouring and chiaro-scuro were undoubtedly elements which he favoured, and in which he moved uncontrolled. Drawing, as he himself candidly confessed, was the part of the art in which he was most defective; and from a desire perhaps to hide this defect, with an over-solicitude to produce a superabundant richness of effect, he was sometimes tempted to fritter his lights, and break up his composition, particularly if it happened to be large, into too many parts: yet, in general, his taste in lines and forms was at the same time grand and graceful; and the taste and skill with which he drew and set together the features of the human face, has never been surpassed by any artist. We would be understood to speak of his finest productions; of the ordinary class among them, we must allow, that the marking favours of manner, and the substance is not always characteristic of flesh.

In execution, though he wanted the firmness and breadth which appertain to the highest style of art, yet the spirit and sweetness of his touch were admirable, and would have been more remarkable, had he been more a master of drawing: but not being able readily to determine his forms, he was obliged to go over and over the same part, till some of the vivacity of his handling was frequently lost; his labour,

bour, however, was never wholly so, for he added to the force and harmony of his pictures by these repetitions; and frequently attained graces by them which would otherwise perhaps have remained unknown.

The numberless instances in which he is known to have borrowed thoughts, both in actions of figures, and effect of colour, seem to impeach his power of invention. But surely it could not proceed from want of a sufficient portion of that high and necessary quality, that he, who produced so many novel combinations, adopted that short-hand path to composition. We see it exemplified in a superior degree in most of his principal productions; and particularly in his whole length and half length portraits; the arrangements of which are no less beautiful and interesting, than new, and entirely his own. These are composed in a taste far surpassing all that had ever been done by his predecessors; uniting the grandeur, simplicity, and fulness of Titian, and the grace and nature of Vandyke, with the artful and attractive effects of Rembrandt.

Most probably he adopted that line of conduct from necessity; driven to it by the immense source of employment which his talents for portraiture showered upon him. He had scarcely time to invent new actions or effects in all cases, or to bestow that study upon them which would have been requisite, and therefore he satisfied himself by endeavouring to infuse into those he borrowed more elegance, more feeling, or more sentiment. How effectually he did this, needs not here be mentioned. One quality he had, which no other painter that ever breathed shares with him in an equal degree, fascination. The effect of his best pictures acts like a charm, and arrests the tasteful beholder with irresistible power. On the works of others we look with approbation, and sometimes with feelings of admiration and delight, or even with a sensation of awe; but in those of Reynolds there is generally an indescribable unity and amenity, which act upon us with most fascinating power, and rivet the attention with superior gratification. No real connoisseur can deny the existence of this quality in his pictures, but wherein it specifically dwells, it is not easy to discover or define. They are not laboured to perfect imitation, indeed they stop very far short of that; yet they present a full image, with a degree of life and animation, that has rarely been displayed upon canvas. It is a dangerous doctrine to advance, and may be abused; but, perhaps, this power may be in great measure owing to his having painted less upon system, than from feeling; and the latter governing the exercise of his pencil, not to the neglect of, but in a superior degree to the influence of the former, necessarily imbued his works with a glow of nature; which, it will be allowed, attracts beyond the power of art. Whencesoever this fascination, of which we speak, proceeds, it must be acknowledged, that no painter ever possessed it like Reynolds.

His historical works are but few. Those, however, exhibit a power, of which it is fair to say, that if it had been early cultivated, and kept in employment, he would most probably have rivalled the great names of antiquity. His poetic and fancy subjects are treated with originality, variety, taste, and sentiment.

The sense of his extraordinary talents was revived and strengthened to its proper medium, by a most just and pleasing tribute paid to his memory in the course of the year 1813: *viz.* a public exhibition of a selection of his works at the gallery of the British Institution, Pall Mall. About 150 pictures, productions of his easel, collected from various possessors, were arranged for the inspection of the public; and presented an assemblage of taste and genius, such as we conceive no other country in the world could boast. At least in an equal number of any other artist's productions, so pleasing a combination of the beauties of the art of painting could no where be found: and these were but a small proportion, indeed, of the number of pictures which he painted. There are engravings from upwards of 700 of his works, and a vast number of others have evidently never been under the engraver's hands. The idea of this token of respect to our great artist originated in conversation at the annual dinner of the Royal Academy, in 1812; when, upon its being proposed to his royal highness the prince of Wales, who was present, he entered most cordially into it, and professed his readiness to lend his own pictures for the purpose. The exhibition being prepared, it was opened on Saturday, the 11th of May, when the members of the institution gave a grand dinner to a large portion of the nobility and the members of the Royal Academy, which was honoured by the presence of the prince regent. After the dinner the rooms were illuminated by lamps, and the company increased and adorned by the admission of ladies, many of whom had been the happy subjects of his ingenious pencil: for he is said to have preserved to posterity the features of three generations of the beauty and fashion of the country.

The pleasure afforded to the country at large by this exhibition was testified by the immense concourse of people that flocked to behold and admire, during the whole time of its remaining open. So that the funds of this excellent institution were well replenished, its object of exalting the honour of the artist and his profession most amply effected, and the country itself exalted in the estimation of the world, by this effective display of native power in an art, the neglect of which had been the source of obloquy upon our climate, as it continues, notwithstanding and more justly, still to be upon our government.

We shall conclude our account of this great and valuable man, by quoting part of an eulogium written by his friend Mr. E. Burke a few hours after the melancholy event, which it commemorates, had taken place. "He possessed," said that clear investigator of character, "the theory, as perfectly as the practice, of his art. To be such a painter, he was a profound and penetrating philosopher.

"In full affluence of foreign and domestic fame, admired by the expert in art, and by the learned in science, courted by the great, caressed by sovereign powers, and celebrated by distinguished poets, his native humility, modesty, and candour, never forsook him, even on surprize or provocation; nor was the least degree of arrogance or assumption visible to the most scrutinizing eye, in any part of his conduct or discourse.

"His talents of every kind, powerful from nature, and not meanly cultivated by letters, his social virtues in all the relations and all the habitudes of life, rendered him the centre of a very great and unparalleled variety of agreeable societies, which will be dissipated by his death. He had too much merit, not to excite some jealousy; too much innocence, to provoke any enmity. The loss of no man of his time can be felt with more sincere, general, and unmixed sorrow.

"Hail! and Farewell!"

REYNOLDS' *Island*, in *Geography*, a small island in the Florida Stream. N. lat. 24°. W. long. 81° 30′.

REYNOSA, a town of Spain, in Old Castile; 35 miles N.W. of Frias.

REYOOR, a town of Hindoostan, in the circar of Condapilly; 15 miles S.E. of Condapilly.

REZ, a river of Ruffia, which runs into the Irbit. N. lat. 57° 50′. E. long. 62° 34′.

REZEMICO, a town of Italy, in the department of the Lario; 20 miles N. of Como.

REZITZA, a town of Ruffia, in the government of Polotfk; 72 miles N.N.W. of Polotfk. N. lat. 56° 25′. E. long. 27° 4′.

REZZATO, a town of Italy, in the department of the Mela; 4 miles E. of Brefcia.

REZZLE, a term provincially fignifying the weezle.

RHA, in *Botany*, ῥα, or ῥᾶ, of Diofcorides, "which fome," fays he, "call ῥῆον," is defcribed by that ancient writer as the produce of the countries above the Bofphorus, from whence it was brought to Greece. "The root is black externally, like the Greater Centaury, but fmaller, and internally of a more reddifh hue, deftitute of odour, loofe, fungous, and rather light." He proceeds to defcribe its flavour and virtues. The plant of Diofcorides has generally been fuppofed one of the rhubarbs of the fhops, which acquired, fubfequently to his time, the name of *Rha-barbarum*, becaufe it was procured from countries deemed barbarous by the Greeks and Romans. What precife fpecies of RHEUM (fee that article) it might be, we prefume not to determine. Sometimes it has been termed *Rhaponticum;* though the latter appellation has alfo been beftowed on a fpecies of *Centaurea*, which Dodonæus and others have thought to be the true ancient *Rha*, or *Rheum*, and which Linnæus, therefore, names *Centaurea Rhapontica*.

RHAAD, in *Ornithology*, a fpecies of *Otis*; which fee.

RHABARBARUM, in *Botany*. See RHA.

RHABDOIDES, Ῥαβδοειδής, formed from ῥάβδος, *rod*, or *ftaff*, and εἶδος, *form*, in *Anatomy*, a name given the fecond true future of the fkull, called alfo the *fagittal future*.

RHABDOLOGY, or RABDOLOGY, in *Arithmetic*, a name fometimes given to the method of performing the two moft difficult and operofe rules, *viz.* multiplication and divifion, by the two eafieft, *viz.* addition and fubtraction, by means of two little rods or laminæ, on which are infcribed the fimple numbers, and which are to be fhifted according to certain rules.

Thefe rods are what we popularly call *Nieper's bones*, from their inventor, a Scottifh baron, who likewife invented logarithms. For their defcription and ufe, fee NIEPER'*s Bones*.

RHABDOMANCY, an ancient method of divination, performed by means of rods or ftaves.

Whence its name, from the Greek ῥάβδος, *rod*, and μαντεια, *divination*.

St. Jerom makes mention of this kind of divination, in his commentary on Hofea, ch. iv. 12. The fame he finds again in Ezekiel, xxi. 21, 22.

If it be the fame kind of divination that is mentioned in the two paffages, rhabdomancy muft have been alfo the fame fuperftition with belomancy.

In effect, the two are ordinarily confounded. The Seventy themfelves tranflate the חצים of Ezekiel, by ῥάβδος, *a rod;* though in ftrictnefs it fignifies an *arrow*.

This however is certain; the inftruments of divination mentioned by Hofea are different from thofe of Ezekiel. In the former it is עצו, *etfo*, מקלו, *maklo*, his *wood*, his *ftaff;* in the latter, חצים, *hhitfim*, *arrows*. Though it is poffible they might ufe rods or arrows indifferently; or the military men might ufe arrows, and the reft rods. It appears by the laws of the Frifones, that the ancient inhabitants of Germany practifed rhabdomancy The Scythians were likewife acquainted with the ufe of it; and Herodotus obferves (lib. iv.) that the women among the Alani fought and gathered together fine ftraight rods or wands, and ufed them in the like fuperftition.

RHABDONALEPSIS, Ῥαβδον Αναληψις, among the Greeks, the Reception or Elevation of the Rod, a feftival kept every year in the ifland of Cos, at which the priefts carried a cyprefs-tree.

RHABDOPHORI, Ῥαβδοφοροι, among the Greeks, officers appointed to preferve peace and good order, and to correct the unruly at their public games.

RHABDUS, Ῥαβδος, among the *Ancients*, the iron rod with which the boys rolled the trochus.

RHACHITIS, in *Surgery*. See RACHITIS and RICKETS.

RHACOMA, in *Botany*, a name adopted by Linnæus from Pliny, and applied to the genus called by Browne *Croffopetalum*, but which proves not diftinct from MYGINDA; fee that article. The real *Rhacoma* of Pliny appears, by his copious account of its characters and qualities, to be fome kind of rhubarb (fee RHA and RHEUM); nor do we pretend to account for the Linnæan application of the name.

RHACOSIS, from ῥακος, *a rag*, in *Surgery*, a ragged, excoriated, and relaxed ftate of the fcrotum.

RHADAMANTHUS, in *Mythology*, one of the three judges or fovereigns of Hades, or the invifible world, to whom was affigned Tartarus, as Erebus was to Minos, and Elyfium to Æacus. He was the brother of Minos, and the fon of Jupiter and Europa; and is faid to have been preferred to the honour of prefiding over Tartarus, on account of the diftinguifhed wifdom and juftice of his adminiftration.

According to Plato, Æacus judged the Europeans; and Rhadamanthus, who had left Crete, and fixed his refidence in Afia, had the Afiatics for his lot, among whom were alfo comprehended the Africans. The ftern Rhadamanthus fuperintends in Tartarus the execution of the fentences which his brother Minos pronounces, after fhaking the fatal urn in which are contained the deftinies of all mortals. The office of Rhadamanthus is defcribed by Virgil, Æneid, lib. iv.

> "Gnoffius hæc Rhadamanthus habet duriffima regna
> Caftigatque auditque dolos, fubigitque fateri,
> Quæ quifque apud fuperos, furto lætatus inani
> Diftulit in feram commiffa piacula mortem."

RHADAMISTUS, in *Entomology*, a fpecies of *Scarabæus;* which fee. It inhabits Tranquebar.

RHADEN, in *Geography*, a town of Weftphalia, in the principality of Minden; 15 miles N.W. of Minden.

RHADES, a town of Africa, in the kingdom of Tunis, anciently called "Ades;" fix miles S.E. of Tunis.

RHÆTEUM, or RHETEUM, in *Ancient Geography*, a promontory in the vicinity of Troy, on which was erected a tomb to Ajax, mentioned by Strabo (l. 13.) and other ancient writers. Horace indeed fays (Sat. l. 2.) that this hero remained without burial; but he deviates from the truth, in allufion to that incident in the tragedy of Ajax, where Sophocles feigns that Agamemnon was unwilling to allow the honours of burial to be conferred upon him, but that he yielded at length to the importunate intreaties of Teucer.

RHÆTIA, a country of Europe, which occupied part of the Alps, and was fituated to the north of Italy, and to the eaft of Helvetia. It is not eafy to afcertain its limits to the north, but we may fay that it was bounded in that quarter by Vindelicia; and, in general, that it correfponded to the country

country of the Grisons, and to the cantons of Uri, Glaris, &c. as far as the "Brigantinus lacus," or lake of Constance: it extended also over the Tyrol. This country was called Western Illyricum, and was divided into Rhætia Prima or Propria, and Secunda, extending towards Swabia, Bavaria, and Austria. This district was subjected to the Romans by Drusus, under the reign of Augustus. Soon afterwards Vindelicia took up arms in their favour, and Tiberius was sent against them, and reduced their country, so that the possessions of the Romans extended as far as the Danube. The whole of this extensive territory had borne the name of Rhætia; but under Dioclesian it was divided, as we have said, into Rhætia Prima and Secunda, the latter of which divisions was Vindelicia. Rhætia, Noricum, and some other territories, became a Roman province, and belonged to the kingdom of the Ostrogoths in Italy; but upon the declension of it, they fell under the dominion of the Franks, about which time the name of Bavarians first became celebrated in history. The principal rivers of Rhætia were the Rhenus or Rhine, the Athesis or Adige, the Oenus or Inn, the Ticinus or Tosin, and Addua. The most considerable places were Curia or Coira, at a small distance east of the Rhenus, and Tridentum or Trent, on the Athesis. Ptolemy, in his geography of Rhætia, reckons upon the Danube the following towns, *viz.* Bragodurum, Dracuina, Viana, and Phæniana; and towards the source of the Rhine, Tagahum, Brigantium, Ebodunum, Drusomagus, and Ectodurum.

RHAGADES, Ῥαγαδες, in *Surgery*, a Greek term used for the chaps or clefts in the lips, hands, anus, and other soft parts of the body.

Rhagades are a sort of fissures, and little chapped ulcers of the œdematous kind; formed of a sharp saline humour, and occasioning a great contraction and straightening of the part, which is by this means shrivelled up like a wet parchment, when held to the fire.

They are chiefly found on the fundament, the neck of the womb, the præputium, lips, &c. sometimes even in the mouth; in which case the patient is not able to speak, chew, or the like.

They are sometimes moist, and of a cancerous nature, eating deep, and difficult of cure; but they are more commonly of a less malignant tendency, being often in the anus the consequence of a diarrhœa, dysentery, or the like.

RHAGADIOLUS, in *Botany*, see LAPSANA; under the fourth species of which its etymology is given.

RHAGAURA, in *Ancient Geography*, a town of Asia, in Aria, between Siphara and Zamuchana. Ptolemy.

RHAGE, a word used by medical writers for a fissure or chap in any part. The stones of grapes are also by some called *rhages*; and by others the same word is made to express the extremities of the fingers or toes.

RHAGEA, in *Ancient Geography*, a town of Asia, in Parthia, near Appha, according to Ptolemy.

RHAGES, a town of Macedonia, on the banks of the river Peneus, about ten miles from Larissa, according to Livy.

RHAGIA, a town of Asia, in Babylonia, towards Arabia Felix, between Jamba and Chiriphe, according to Ptolemy.

RHAGIANA, a town of Gedrosia, near the "Portus Mulierum;" so called in the translation of Ptolemy; but in the text of Ptolemy it is called "Rapava."

RHAGODIA, in *Botany*, from ῥαξ, *a berry*, because its little pulpy fruit affords a principal mark of distinction between this genus and several others, to which it is nearly related.—Brown Prodr. Nov. Holl. v. 1. 408. Ait. Hort. Kew. v. 5. 440.—Class and order, *Polygamia Monoecia*, Brown; but we should rather say *Pentandria Digynia*, though some of the flowers are defective as to the stamens or the pistil. Nat. Ord. *Holeraceæ*, Linn. *Atriplices*, Juss. *Chenopodeæ*, Decandolle and Brown.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, concave, permanent, in five deep ovate segments. *Cor.* none. *Stam.* Filaments five, awl-shaped, opposite to the segments of the calyx, and about as long; anthers roundish, two-lobed. *Pist.* Germen orbicular, depressed; styles two, divaricated, short; stigmas simple. *Peric.* Berry orbicular, depressed, encompassed underneath by the calyx. *Seed* solitary, the shape of the berry, "furnished with albumen, and a double coat." *Brown.*

Obs. Labillardiere and Brown describe some flowers as wanting the stamens, others the pistil, though the rest have both. In this polygamous character, but especially in the nature of the fruit, which is a true *bacca*, this genus differs from CHENOPODIUM, as well as from KOCHIA, and other neighbouring genera, of Mr. Brown; see those articles. The stamens are sometims fewer than five. *Brown.*

Eff. Ch. Calyx inferior, in five deep segments. Corolla none. Berry depressed, encompassed with the permanent calyx. Seed solitary, orbicular, depressed. Some male or female flowers are interspersed.

The species, all natives of New Holland, are generally shrubby, rarely herbaceous. *Leaves* almost always alternate, simple, often clothed with mealy powder. *Flowers* either spiked or conglomerated, destitute of *bracteas*.

1. R. *Billardieri.* (Chenopodium baccatum; Labill. Nov. Holl. v. 1. 71. t. 96.)—Shrubby, erect, without thorns. Leaves entire, linear-oblong or lanceolate, flat; powdery beneath. Spikes branched. Native of New South Wales, as well as of the southern coast of New Holland. *Stem* shrubby, branched, five feet or more in height, with round, leafy branches, striated when dry. *Leaves* stalked, spreading, an inch and a half, or two inches, long, and one-third of an inch broad, sharpish; tapering at the base. *Flowers* small, greenish, in terminal, much compounded, or panicled, spikes. *Berries* red, about the size of mustard-seed.

2. R. *crassifolia.*—Shrubby, erect, without thorns. Leaves entire, oval, or linear-oblong, fleshy, convex and powdery beneath. Spikes branched.—Gathered by Mr. Brown, on the south coast of New Holland.

3. R. *linifolia.*—Somewhat shrubby, decumbent. Leaves entire, linear-lanceolate, flat, stamens one or two. Found by the same botanist, in the tropical part of New Holland.

4. R. *hastata.* Ait. n. 1.—Somewhat shrubby, erect. Branches diffuse. Leaves nearly opposite, hastate, somewhat rhomboid, entire, very smooth. Spikes terminal, leafless.—Native of New South Wales, from whence it was sent to Kew by Mr. Peter Good, in 1803. This is a hardy shrub, flowering with us in June and July, and appears to be the only species of the genus before us, that has, as yet, been cultivated in England.

5. R. *parabolica.*—Shrubby, erect, without spines. Leaves triangular, obtuse, powdery. Spike branched.—Observed by Mr. Brown, on the south coast of New Holland, but without fruit.

6. R. *spinescens.*—Shrubby, erect; the young branches becoming spines. Leaves partly opposite, hastate, somewhat rhomboid, entire; powdery and hoary on both sides. Spikes simple.—From the south coast.

7. R. *nutans.*—Herbaceous, prostrate. Branches ascending when in fruit, drooping at the extremity. Leaves opposite, lanceolate-hastate, acute.—Gathered by Mr. Brown,

on

on the south coast of New Holland, as well as in Van Diemen's island.

RHAGOIDES, Ῥαγοειδης, in *Anatomy*, the second coat or tunic of the eye; more usually called uvea.

It has its name rhagoides, as resembling a grape-stone.

In the tunica rhagoides is the hole called the pupil.

RHAHAANS, in *History*, a name given to the priests of the Birman empire, to whom are assigned kiouns, or convents; which are different in their structure from common houses, and much resemble the architecture of the Chinese. These buildings are constructed of wood; the roof is composed of different stages, supported by strong pillars; the inside comprehends one large hall; the whole house is open at the sides; some are curiously carved with various symbolic representations of the divinity. There are no apartments for the private recreation of the Rhahaans; publicity being the prevailing system of conduct among the Birmans, who admit of no secrets either in church or state. From the number of convents in the neighbourhood of Rangoon, the Rhahaans and Phonghis, who are an inferior order of priests called Tallapoins, are presumed by colonel Symes to exceed 1500; including in this estimate those in their novitiate. The age of induction into these convents, is generally from eight to twelve years, and young persons are introduced into them with great formality and ceremony. Parents vie with each other in obtaining this honour for their children, and spare no cost on the occasion of their admission; the principal charge consisting in entertainments, and the customary presents to the Rhahaans. When a boy is to be introduced into a convent, either as a temporary resident, or with a view to future consecration, his friends prepare their offerings of cloth, rice, preserves, fruit, fans, cushions, mats, and houshold utensils. On an appointed day he parades the streets, dressed in yellow, and mounted on a horse richly caparisoned, led by two servants: a band of music goes before, and a party of Rhahaans encircle him: his male friends follow in a troop, and the females of their families bring up the rear, the latter carrying on their heads the offerings meant for the Rhahaans. Thus they proceed to the convent of which the novice is to become a member, where he is presented in form to the senior of the brotherhood. This ceremony is repeated three times, and at each perambulation, fresh presents are to be provided.

The Rhahaans, like the Carmelites, go barefooted, and have their heads close shaven, on which they never wear any covering. Yellow is the only colour worn by the priesthood: they have a long loose cloak, which they wrap round them, so as to cover most part of the body; they profess celibacy, and to abstain from every sensual indulgence. The prescribed punishment for a Rhahaan detected in an act of incontinence is, expulsion and public disgrace; the delinquent is seated on an ass, and his face daubed with black paint interspersed with spots of white; he is thus led through the streets, with a drum beating before him, and afterwards turned out of the city: but such instances of degradation are very rare. The juniors are restricted from wandering about licentiously, either by day or night. There is a prior in every convent, who has a discretionary power to grant permission to go abroad.

The Rhahaans never dress their own victuals, holding it an abuse of time to perform any of the common functions of life, which, so long as they occupy, must divert them from the abstract contemplation of the divine essence. They receive the contributions of the laity ready cooked, and prefer cold food to hot. At the dawn of the morning they begin to perambulate the town, to collect supplies for the day: each convent sends forth a certain number of its members, who walk at a quick pace through the streets, supporting with the right arm a blue lackered box, in which the donations are deposited; these usually consist of boiled rice mixed with oil, dried and pickled fish, sweetmeats, fruit, &c. During their walk, they never cast their eyes to the right nor to the left, but keep them fixed on the ground; they do not stop to solicit, and seldom even look at the donors, who appear more desirous to bestow, than the others to receive. The Rhahaans eat but once a day, at the hour of noon. A much larger quantity of provision being commonly procured than suffices for the members of the convent, the surplus is disposed of, as charitably as it was given, to the needy stranger, or the poor scholars who daily attend them to be instructed in letters, and taught their moral and religious duties.

In the various commotions of the empire, colonel Symes says, that the Rhahaans take no active share, nor do they publicly interfere in politics, or engage in war: by this prudent conduct they excite no resentment: the Birmans and Peguers professing the same religion, the conquerors, to whichsoever party they belonged, equally respected the ministers of their faith. The head of the Rhahaans at Rangoon, called Seredaw, is treated with great veneration. He lives in a very handsome monastery half a mile from the town, on the road leading to Shoedagon, or temple. He is in no respect distinguished, as to his outward appearance, from the common Rhahaans. He goes every day, at the same hour, to the temple, to offer his devotions, and performs the journey, which is about four miles, on foot. In his conversation with Symes he betrayed a worldly pride inconsistent with his years (being about seventy-five) and sacred function: he announced, with much pomp, that he was the head of the church at Rangoon, and ostentatiously displayed, engraven on iron plates, his sacerdotal titles, which had been conferred on him by the present and the late king. Formerly there were nunneries of virgin priestesses, who, like the Rhahaans, wore yellow garments, cut off their hair, and devoted themselves to chastity and religion; but these were not long ago abolished, as being injurious to the population of the state. At present there are a few old women, who shave their heads, wear a white dress, follow funerals, and carry water to the convents; and these venerable dames are treated with some portion of respect. Symes's Ava, vol. ii.

RHAIADAR, or RHAYADER, in *Geography*, a borough and market-town in the cwmwd of Glynn-Jeithon, cantref of Maelienydd (now called the hundred of Rhayader), county of Radnor, South Wales, is situated on the banks of the river Wye, at the distance of 20 miles N.W. from New Radnor, and 176 W.N.W. from London. This place is a borough by prescription, and lays claim to a very high antiquity. It is governed by a bailiff, who is annually elected at a court-leet, held in the town-hall, at which also the burgesses are chosen by a town jury. Rhayader is one of the five contributary boroughs to return a representative to serve in parliament for the town of New Radnor. This place was formerly of much greater consequence and extent than at present. On Cefn-Ceido, about half a mile to the north-east, is a tract of land, called Pant-yr-Eglwys, where, according to tradition, a church anciently stood, which was included within the precincts of the borough. The great sessions for the county were at one time held here; and the county-court alternately met at New Radnor and Rhayader, till removed from the latter place to the town of Presteigne, in the reign of Henry VIII. The gaol for the security of criminals then stood on a spot of ground now occupied by a Presbyterian meeting-house; and the place of execution was

at

at the north end of the town, near a houſe known by the appellation of Pen-y-Maes. At preſent Rhayader conſiſts of four ſtreets which interſect each other at right angles, and lie nearly parallel to the four cardinal points. In the wide ſpace formed by the interſection of theſe ſtreets ſtands the town-hall, which is a handſome building, rebuilt by ſubſcription in 1762. The church is a plain ſtructure, ornamented with a tower at one end; beſides which there is a place of worſhip for Preſbyterians and another for Methodiſts. The grammar-ſchool was erected A.D. 1793, and has an endowment for the education of a limited number of poor children. The borough of Rhayader is a diſtinct pariſh of itſelf, and is exempt from the payment of county rates. The market-day here is Wedneſday, weekly; and there are fairs on the 6th and 27th of Auguſt, 26th September, 14th October, and 3d December, for horſes, ſheep, and cattle; beſides three great markets in May. The chief ſupport of this town ariſes from the manufacture of woollens, principally flannel. According to the population returns of 1811, the pariſh contained 97 houſes and 446 inhabitants.

On an eminence to the N.W. of the town ſtood the ancient caſtle of Rhayader, which was erected, in the year 1178, by Rhys-ap-Gruffydd, prince of South Wales, in order to check the incurſions of the Normans, who, at that period, made great irruptions in the marches of Wales. In 1194, prince Rhys having been ſurprized and taken priſoner by his own ſons, this caſtle was beſieged and compelled to ſurrender to the ſons of Cadwalhon-ap-Madawe of Maelienydd, by whom it was fortified for their own uſe. In the year 1231, after Llywelyn, prince of North Wales, had taken and deſtroyed the caſtle of Montgomery, he marched hither, and viſited the caſtle of Rhayader with a ſimilar fate. It was rebuilt, however, and continued to be a place of defence till the civil wars in the ſeventeenth century, when it was diſmantled and totally deſtroyed; the foſſe by which it was furrounded being the only veſtige of it remaining at the preſent day. The tower, or citadel, ſtood in a direct line between the caſtle and the gaol, overlooking the river. The mount adjacent is ſtill denominated Tower-hill. Near this place a ſtone bridge is thrown over the Wye, which the Welſh call Rhaiadr-Gwy, in alluſion to the rumbling noiſe its impetuous waters make amidſt the rocks. The only religious houſe, recorded to have been ſituated at Rhayader, was a convent of Dominican, or Black friars, founded ſoon after their firſt arrival in England, A. D. 1221. This houſe was ſuppreſſed in the 31ſt year of king Henry VIII.

In the immediate vicinity of Rhayader, the ſcenery of the Wye is peculiarly grand. Raging in its rocky bed, this river is ſeen through the light foliage of impendent trees, ſometimes precipitating its waters over a bold ledge of rock, and ſometimes ſearching its way among protruding crags, in a contracted ſheet of gliſtening foam. The mountains by which the vale of Rhayader is environed, diſplay a wild and rugged character, and are noted, according to local tradition, as being the place of ſhelter in which king Vortigern eluded the ſearch of Hengiſt, after his alleged murder of the Britiſh nobles at Stonehenge. Theſe hills abound with various kinds of minerals, particularly lead and copper. There are ſeveral cairns in this neighbourhood, the moſt remarkable of which is that of Tommen Sant Ffraid, on the S.W. ſide of the town, in the pariſh of Cwm-y-dan-Ddwr, ſuppoſed to be the cemetery of Saint Fraid, the Popiſh tutelary ſaint of that pariſh. Carliſle's Topographical Dictionary of Wales, 4to. 1811. A Tour throughout South Wales and Monmouthſhire, by J. T. Barber, F.S.A. 8vo. 1803.

RHAIDR, a river which riſes in the E. part of Merionethſhire, North Wales, and runs into the Severn on the borders of Shropſhire.

RHAIR, a conſiderable river of Hindooſtan, which runs by the ſouth ſide of Shawpour. The ſtream, which is about 100 yards wide and four feet in depth, daſhes with great rapidity over a bed of rock; which prevents its being navigable for large boats. This river riſes in the hills and foreſts of Surgooja, and after being joined by the Bijool and Gutauin, falls into the Soane near Agowry.

RHAMNÆ, or Rhannæ, in *Ancient Geography*, a people of India, in the mountains near the river Namadus. Ptolemy.

RHAMNI, in *Botany*, a natural order of plants in Juſſieu, being the 95th in his ſeries, or the 13th of his 14th claſs, and owing its name to the principal genus. See Rhamnus.

See the character of the claſs under Ficoideæ. The order is thus defined.

Calyx inferior, of one leaf, with a definite number of ſegments in the limb. *Petals* five, rarely four or ſix, and very rarely wanting, inſerted into the upper part of the calyx, or into its diſk, either oppoſite to, or alternate with, its ſegments, and equal to them in number; ſometimes reſembling little ſcales, and furniſhed with claws; ſometimes united by their broad baſes. *Stamens* of the ſame number as the petals, and inſerted into the ſame part, either alternate with them, or oppoſite to them. *Germen* ſuperior, encompaſſed below with the diſk of the calyx. *Styles* either ſolitary, or of ſome definite number. *Stigmas* one or more. *Fruit* ſuperior; in ſome inſtances pulpy, either with many cells, or many nuts, the cells, or nuts, ſingle-ſeeded; in other caſes capſular, of many cells and many valves, the partitions from the middle of each valve, and the cells containing either one or two ſeeds. *Corculum* flat and ſtraight, ſurrounded with a fleſhy albumen. *Stem* arboreous or ſhrubby. *Leaves* either alternate or oppoſite, accompanied by *ſtipulas*, that are often very minute.

Section 1. *Stamens alternate with the petals. Fruit capſular. Staphylea; Euonymus;* and *Celaſtrus* of Linnæus; with *Polycardia* of Lamarck.

Sect. 2. *Stamens alternate with the petals. Fruit a drupa or berry.* Some genera of this ſection have the petals connected by their broad baſe.

Myginda; Goupia of Aublet, which is *Gloſſopetalum* of Schreber; *Rubentia* of Commerſon, certainly the ſame genus with Jacquin's *Elæodendrum*, as Juſſieu indeed ſuſpected; *Caſſine; Schrebera* of Linnæus, a genus founded altogether in error, as we ſhall explain in its proper place; *Ilex;* and *Prinos.*

Sect. 3. *Stamens oppoſite to the petals. Fruit drupaceous.*

Mayepea of Aublet, erroneouſly placed here, as belonging really to the *Jaſmineæ* (ſee Mayepea); *Samara; Rhamnus; Ziziphus; Paliurus;* the two laſt ſeparated from the Linnæan *Rhamnus*, by Juſſieu. See Paliurus.

Sect. 4. *Stamens oppoſite to the petals. Fruit three-lobed.*

Colletia of Commerſon, Lamarck Illuſtr. t. 129; *Ceanothus; Hovenia;* and *Phylica;* to which is to be added Lasiopetalum; ſee that article.

Sect. 5. *Genera akin to Rhamni, their germen moſtly ſuperior.*

Brunia of Linnæus, ſome of whoſe reputed ſpecies have the germen ſuperior, others inferior; and *Bumalda* of Thunberg.

Sect. 6. *Genera akin to Rhamni, but differing in having an inferior germen.*

Gouania; Plectronia, dubiouſly admiſſible here, as we have obſerved in its proper place; *Carpodetus* of Forſter;

Aucuba

Aucuba of Thunberg; and *Glossoma* of Schreber, which is Aublet's *Votomita*.

RHAMNOATZ, in *Geography*, a town of Sweden, in Westmannland; 20 miles N. of Stroemsholm.

RHAMNOIDES, in *Botany*, a name given by Tournefort, and others, to a genus of plants, called by Linnæus *hippophae*; which see.

RHAMNUS, in *Ancient Geography*, a borough of Attica, belonging to the Ajantide tribe, 60 stadia from Marathon, in a northerly direction from the Ægean sea, in a place where the land formed a small peninsula or Chersonesus. The houses were on the sea-coast; and upon an eminence was the temple of Nemesis, in which was a fine statue of the goddess, made by Phidias, of marble, which the Persians had brought from Paros for the purpose of forming a trophy, and which had been found in their camp after the battle of Marathon: the pedestal was adorned with four basso relievos, representing different subjects of Grecian history. Leda is also exhibited presenting Helena to her mother Nemesis. See NEMESIS.

RHAMNUS, in *Botany*, so called by the ancient Romans, and by the Greeks ῥαμνος; words derived, according to De Theis, from the Celtic *Ram*, a head or tuft of branches, which is the origin of the Latin *ramus*, &c. and of the French *Rame*, *ramier*, &c.—Linn. Gen. 105. Schreb. 142. addend. 823. Willd. Sp. Pl. v. 1. 1092. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 261. Prodr. Fl. Græc. Sibth. v. 1. 157. Ait. Hort. Kew. v. 2. 14. Juss. 380. Lamarck Illustr. t. 128. Gærtn. t. 106.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Dumosæ*, Linn. *Rhamni*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, urceolate; its limb in five spreading, acute, equal, coloured segments; the base permanent. *Cor.* Petals five, minute, between the segments of the calyx, opposite to the stamens, converging. *Stam.* Filaments as many as the petals, awl-shaped; anthers small. *Pist.* Germen roundish; style thread-shaped, equal to the stamens; stigma in various divisions. *Peric.* Berry roundish, naked, divided into fewer cells than there are segments of the calyx. Seeds solitary, roundish, gibbous on one side, compressed on the other.

Obs. We follow Jussieu and Schreber (in his addenda) in our denomination of the different parts of the flower, instead of taking the calyx for a corolla, with Linnæus. The genera of PALIURUS and ZIZIPHUS, separated from the original Linnæan *Rhamnus*, will be found in their proper places. *Frangula* and *Alaternus* of Tournefort have no just pretensions to be removed from the present genus.

Ess. Ch. Calyx urceolate. Petals five, opposite to the stamens. Berry superior.

We shall briefly define the species which authors have retained in *Rhamnus*, adding some new ones. The whole are shrubby, sometimes climbing. *Leaves* simple, undivided, stalked, veiny; mostly alternate. *Flowers* lateral, small, green or yellowish; sometimes with only four segments, petals and stamens, and in that case often dioecious, or polygamous, as in the first section.

Section 1. *Branches armed with terminal thorns.*

1. R. *catharticus*. Purging Buckthorn. Linn. Sp. Pl. 279. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 1629. Woodv. Med. Bot. t. 114. Fl. Dan. t. 850. (R. solutivus; Ger. Em. 1337, with Clusius's figure of the following species. Spina infectoria; Matth. Valgr. v. 1. 143.)—Flowers four-cleft, polygamous. Leaves ovate. Stem erect. Berry with four seeds.—Native of woods and hedges throughout Europe, especially in moist situations. This is the white-thorn of the modern Greeks. A rigid bushy *shrub*, nearly smooth in every part; its branches terminating in strong thorns. *Leaves* serrated, with several lateral ribs. *Flowers* from the same buds as the leaves, yellowish-green, mostly, but not altogether, dioecious. *Stigma* four-cleft. *Berry* round, black, very purgative, when unripe affording a yellow dye.

2. R. *infectorius*. Turkey-berry Buckthorn, or Graine d'Avignon. Linn. Mant. 49. Willd. n. 2. Ait. n. 2. (R. catharticus minor; Arduin. Mem. 78. t. 14. R. solutivus minor; Ger. Em. 1337. Spina infectoria pumila prima; Clus. Hist. v. 1. 111.)—Flowers four-cleft, dioecious. Stem procumbent.—Native of the south of Europe. Frequent in rough stony places in Greece, and rightly considered by Dr. Sibthorp as the Λυκιον, *Lycium*, of Dioscorides. The unripe berries are much used for dyeing, and imported in great quantities into England. They are what give the yellow colour to Turkey leather, or yellow morocco. This shrub is very nearly related to the first species, but grows procumbent, not erect, and the *leaves* are smaller and narrower. Gerard observes, that the segments of the *calyx* are but the length of the tube; not longer, as in *catharticus*; and that the *stigmas* are two, reflexed. *Fl. Gallopr.* 462. The *stipulas* are linear; not awl-shaped, as in the former; but we dare not rely on that circumstance, without further examination.

3. R. *lycioides*. Box-thorn Rhamnus. Linn. Sp. Pl. 279. Willd. n. 3. Ait. n. 3. Cavan. Ic. v. 2. 66. t. 182. (R. tertius, fortè niger Theophrasti; Clus. Hist. v. 1. 110. R. tertius Clusii; Ger. Em. 1334.)—Leaves nearly linear, obtuse, entire.—Native of Spain; frequent on the limestone hills of Valentia. *Cavan.* Differs widely from both the former in the narrow and entire *leaves*, tapering down into their slender *footstalks*.

4. R. *Erythroxylon*. Red-wood Buckthorn. Pall. Ross. v. 1. p. 2. 26. t. 62, and t. 100. f. 8. Willd. n. 4.—Leaves linear-lanceolate, serrated, rather acute.—Native of dry rocky places in Siberia.—The strongly serrated and acute *leaves* distinguish this from the last. A variety with smaller, more finely serrated, *leaves*, is Pallas's *R. lycioides*, t. 63.

5. R. *oleoides*. Olive-leaved Buckthorn. Linn. Sp. Pl. 279. Willd. n. 5. Ait. n. 4. (R. secundus; Clus. Hist. v. 1. 110. Ger. Em. 1334.)—Leaves obovate, entire; reticulated with veins beneath.—Native of Spain, *Alstroemer*; of Barbary, *Desfontaines*; of the southern part of Greece, and the island of Milo, *Sibthorp*. The shorter obovate *leaves*, copiously reticulated with veins, especially at the back, differ materially from those of *lycioides*. The *fruit* moreover has a much shorter stalk, though it is not so perfectly sessile as in Clusius's figure, which nevertheless we cannot hesitate to refer to this species.

6. R. *prunifolius*. Plum-leaved Buckthorn. Sm. Prodr. Fl. Græc. Sibth. n. 549. (R. creticus, amygdali folio minori; Tourn. Cor. 41.)—Stem procumbent. Flowers flattish, four-cleft, dioecious. Leaves obovate, obtuse, crenate, naked.—Found on the higher mountains of Crete.—Like the last in habit, but distinguished by its crenate, or somewhat serrated, *leaves*. *Stem* depressed, or procumbent, with many entangled branches. The female *flowers* have occasional rudiments of *stamens*. *Style* cloven half way down. We find no figures referrible to this or the following.

7. R. *crenulatus*. Teneriffe Buckthorn. Ait. n. 5. Willd. n. 6.—Stem erect. Flowers three or four-cleft, dioecious. Leaves elliptic-oblong, bluntly serrated, permanent.—Native of the Canary islands; *Masson*. Brought in 1778 to Kew, where it blossoms in the greenhouse in March. A stout, erect, much-branched *shrub*. The *leaves* are finely reticulated beneath.

8. R. *saxatilis*. Rock Buckthorn. Jacq. Austr. t. 53. Linn. Sp. Pl. 1671. Willd. n. 7. Ait. n. 6. (R. solutivus

tivus pumilus; Ger. Em. 1337. Spina infectoria pumila secunda; Cluf. Hift. v. 1. 112.)—Stem fpreading. Flowers four-cleft, dioecious. Leaves obovate, acute, ferrated, deciduous.—Native of Auftria, Switzerland, Italy, and Greece. The rigid branched *ftems* are more fpreading or diffufe than thofe of *R. crenulatus;* the *leaves* deciduous, much lefs evidently reticulated. The *flowers* are pale yellow. *Stigma* in two deep acute divifions. *Berries* black.

9. R. *theezans.* Tea Buckthorn. Linn. Mant. 207. Willd. n. 8. (R. Thea; Ofbeck's Travels, v. 1. 375.)—Leaves ovate, finely ferrated; paler beneath. Flowers in terminal fpikes, five-cleft.—Native of China.—A *fhrub* fix feet high, with long, roundifh, downy, fpreading *branches;* the lateral ones bearing hairy terminal fpikes of *flowers,* and fubfequently becoming fpinous. *Leaves* an inch long, fomewhat heart-fhaped, befet with fine fharp ferratures; fhining and reticulated above; paler, opaque, and more even beneath. The poor people in China are faid to ufe the leaves as a fubftitute for tea.

Sect. 2. *Without thorns, or prickles.*

10. R. *Sarcomphalus.* Timber Buckthorn. Linn. Sp. Pl. 280. Willd. n. 9. (Sarcomphalus; Browne Jam. 179.)—Leaves oval, coriaceous, emarginate, entire. Flowers in denfe, corymbofe, filky tufts.—Native of Jamaica. Browne fays it is one of the beft timber-woods in the ifland, and rifes generally to a very confiderable height. The *trunk* is often above two feet and a half in diameter, covered with a thick fcaly *bark.* *Wood* hard, dark-coloured, clofe-grained. *Leaves* about three inches long, and two broad, fmooth, with a ftrong mid-rib, and many interbranching veins. Browne's generic name applies to the thick, flefhy, umbilicated *nectary,* or receptacle of the flower. He defcribes no *petals.* The *ftyle* is cloven, with two acute *ftigmas.* *Berry* of two cells.

11. R. *ferreus.* Iron-wood Buckthorn. Vahl. Symb. v. 3. 41. t. 58. Willd. n. 10. Mart. n. 10.—"Leaves oblong-ovate, emarginate, membranous, fmooth, entire. Flowers in axillary umbels."—Native of the ifland of Santa Cruz; *Von Rohr* and *Weft.* *Branches* round, fmooth, afh-coloured. *Leaves* an inch or more in length, very finely ribbed and veined. *Umbels* on fhort ftalks. *Vahl.*

12. R. *lævigatus.* Polifhed Buckthorn. Vahl. ibid. Willd. n. 11. Mart. n. 11.—"Leaves oblong, entire, coriaceous, fmooth. Flowers axillary, about two together."—Found in the fame ifland. *Weft.* *Branches* round, fmooth, afh-coloured. *Leaves* an inch and half long, paler and yellowifh at the edges, efpecially the younger ones; fcarcely veiny on the upper fide; not at all fo underneath. *Flowers* two or three together, on very fhort, fimple, fmooth ftalks. *Calyx* fmooth. *Stigmas* two. *Vahl.*

13. R. *tetragonus.* Square-branched Cape Buckthorn. Linn. Suppl. 153. Willd. n. 12. Thunb. Prodr. 44.—"Leaves ovate, entire, fmooth, feffile. Branches fquare."—Gathered by Thunberg, at the Cape of Good Hope. We have feen no fpecimen, nor is there any figure of this fpecies.

14. R. *polifolius.* Poley-leaved Buckthorn. Vahl. Symb. v. 3. 41. Willd. n. 13.—Leaves lanceolate, entire; fnow-white and downy beneath. Flowers axillary, nearly feffile, moftly folitary.—Suppofed to be a native of New Zeeland. *Branches* flender, hoary; downy when young. *Leaves* hardly an inch long, pointed; fmooth and fomewhat wrinkled above. *Footftalks* very fhort, downy.

15. R. *valentinus.* Valentia Buckthorn. Willd. n. 14. (R. pumilus; Cavan. Ic. v. 2. 65. t. 181.)—Leaves roundifh-elliptical, minutely crenate, nearly feffile. Flowers four-cleft. Style deeply three-cleft. Berry dry.—Gathered by Cavanilles, on the mountains of Meca and Palomera, in the kingdom of Valentia, flowering in May. If he be correct as to the nature of the *fruit,* this is a very diftinct fpecies; otherwife its habit is very like *pumilus* hereafter defcribed. The *ftems* are fhort and depreffed. *Leaves* on very fhort ftalks, and obfcurely crenate. *Flowers* hermaphrodite, four-cleft. *Style* divided to the bafe into three parts. *Capfule,* or dry *berry,* of three cells.

16. R. *cubenfis.* Cuba Buckthorn. Linn. Sp. Pl. 281. Willd. n. 15. Jacq. Hort. Vind. v. 3. 28. t. 49.—"Leaves rugofe, entire, downy. Flowers hermaphrodite. Capfule of three cells."—Native of bufhy places near the fea, in the ifland of Cuba. We have not examined any fpecimen, but by Jacquin's account, this appears rather to have the fruit of a *Ceanothus.* The *petals* indeed are oppofite to the *ftamens,* which is an important character of *Rhamnus.* The *fruit* however is not a dry *berry,* but a true *capfule,* with elaftic valves.

17. R. *colubrinus.* Bahama Red-wood Buckthorn. Linn. Sp. Pl. 280. Willd. n. 16. Ait. n. 7. Jacq. Hort. Vind. v. 3. 28. t. 50. (Arbor baccifera indica, foliis majoribus fplendentibus, flore pentapetalo; Comm. Hort. v. 1. 175. t. 90.)—Leaves ovate, entire, with rufty footftalks. Flowers monogynous, erect. Capfules three-lobed.—Native of the Bahama iflands; introduced into our ftoves by Catefby, in 1726. This has alfo the *fruit* of *Ceanothus,* to which genus Miller refers it.

18. R. *dauricus.* Daurian Buckthorn. Pall. Rofs. v. 1. p. 2. 25. t. 61, catharticus. Willd. n. 17. (Cornus foliis citri anguftioribus; Amman. Ruth. 200. t. 33.)—Leaves ovate, ferrated, veiny; tapering at the bafe. Flowers four-cleft, dioecious.—Found by Gmelin and Pallas on the banks of the river Argunus in Dauria. The *wood* is red, and called Sandal-wood by the Ruffians. The afpect of the *fhrub* is much like *R. catharticus,* but there are no thorns. Pallas's names, pages, and references are wonderfully confufed in this, and too many other, parts of his pompous book.

19. R. *alpinus.* Alpine Buckthorn. Linn. Sp. Pl. 280. Willd. n. 18. Ait. n. 8. (R. n. 823; Hall. Hift. v. 1. 366. t. 40. Frangula ora folii ferrata; Hall. Enum. 164. Alnus nigra baccifera, rugofiore folio, feu major; Bauh. Hift. v. 1. 562. Creutzbeer; Lonic. Kreuterb. 59?)—Stem erect. Leaves elliptic-oblong, with glandular crenatures; fomewhat heart-fhaped at the bafe; veins hairy at the back. Flowers dioecious. Stigma four-cleft.—Native of the alps of Switzerland, Dauphiny, Auftria, Carniola, &c. Gathered probably by Dr. Sibthorp on mount Parnaffus; fee n. 21. A *fhrub,* eight or ten feet high, erect, with a fmooth grey bark. *Leaves* two inches or more in length, broadly elliptical, occafionally obtufe or acute; more or lefs heart-fhaped at the bafe: finely and regularly crenate throughout, with rounded glandular teeth; fmooth, except that the numerous ftraight parallel veins are hairy beneath, efpecially at their origin. *Flowers* copious, axillary, ftalked, four-cleft, dioecious. *Stigma* in four narrow deep fegments. *Berry* black, of three cells, with moftly a feed in each. The female *flowers* have the rudiment of a ftyle, according to Wulfen in Jacq. Coll. v. 3. 16, but the fhrub is neverthelefs perfectly dioecious.

20. R. *pumilus.* Dwarf Rock Buckthorn. Linn. Mant. 49. Willd. n. 19. Ait. n. 9. Jacq. Coll. v. 2. 141. t. 11. (R. rupeftris; Scop. Carn. v. 1. 164. t. 5, bad. Villars Dauph. v. 2. 538.)—Stem proftrate. Leaves fomewhat obovate, crenate, fmooth on both fides. Stigma three-cleft.—Native of mount Baldus, and the alps of Dauphiny and Carniola. We have gathered it on mount Cenis. This is a fmall depreffed *fhrub,* creeping clofe to the rocks. The

leaves

leaves are ſmaller than the laſt, with broader leſs numerous crenatures, and we find them alſo tapering conſtantly at the baſe, not inclined to be heart-ſhaped, as Scopoli and Wulfen (in Jacquin), both repreſent them. The latter erroneouſly deſcribes and delineates a ſimple capitate *ſtigma;* in our ſpecimens, and thoſe of Villars, that part is deeply three-cleft. We ſee no reaſon to believe the *pumilus* of this laſt author diſtinct from his *rupeſtris*. The *flowers* of our *pumilus* are deſcribed, by moſt writers, as having all perfect *ſtamens* and *piſtils*, but Villars ſays they appeared to him dioecious.

21. R. *pubeſcens*. Downy Mountain Buckthorn. Sm. Prodr. Fl. Græc. Sibth. n. 552. Fl. Græc. t. 239, unpubliſhed.—Leaves obovate-rhomboid, villous, nearly entire. Flowers dioecious. Style deeply divided.—Gathered by Dr. Sibthorp on mount Parnaſſus. This is a knotty, zigzag, ſpreading, not very upright, *ſhrub*, vyeing in magnitude with *R. alpinus*, for which poſſibly Dr. Sibthorp might at one time have taken it, when he made a memorandum of *alpinus* being found on Parnaſſus; as we obſerve no ſpecimen in his collection to confirm ſuch memorandum. It is, nevertheleſs, extremely probable that both ſpecies may grow there. The preſent is very diſtinct from *alpinus* in having downy, and nearly entire *leaves*. The *flower-ſtalks* and *calyx* are alſo downy. *Petals* roundiſh, concave, found in the *male flowers* only. *Female flowers* on a ſeparate plant. *Style* divided nearly to the baſe, with only two *ſtigmas*. This ſpecies is more akin to the following than to any of the foregoing.

22. R. *Frangula*. Alder Buckthorn, or Berry-bearing Alder. Linn. Sp. Pl. 280. Willd. n. 20. Fl. Brit. n. 2. Engl. Bot. t. 250. Fl. Dan. t. 278. (Frangula; Camer. Epit. 978. Matth. Valgr. v. 2. 609. Alnus nigra, five Frangula; Ger. Em. 1470.)—Leaves obovate, entire, ſmooth. Style ſimple, very ſhort. Stigma cloven.—Native of buſhy places in the north of Europe more eſpecially, though Dr. Sibthorp obſerved it about Conſtantinople. It flowers, like moſt of the ſpecies of *Rhamnus*, in the ſpring. The *ſtem* is ſhrubby, about four feet high. *Leaves* two or three inches long and about one broad, ſomewhat pointed. *Flowers* whitiſh, with very minute *petals* and *ſtamens*, in the ſame individuals with the *piſtils*. *Style* very ſhort, with two ſmall ſegments to the *ſtigma*. *Berry* black, roundiſh, with ſeldom more than two *ſeeds*, though we have ſeen three, in which caſe, we preſume, there muſt have been a three-cleft *ſtigma*. Theſe *berries* are ſometimes mixed, by herb gatherers, with thoſe of the true Buckthorn, n. 1, or ſubſtituted for thoſe berries; but the ſmaller number of ſeeds betrays the deception. Their qualities perhaps differ very little.

23. R. *latifolius*. Broad-leaved Azorian Buckthorn. L'Herit. Sert. Angl. 5. t. 8. Willd. n. 21. Ait. n. 11.—Leaves elliptical, pointed, entire. Calyx hairy. Style ſimple.—Gathered by Mr. Maſſon in the Azores. He ſent it to Kew in 1778, and it bloſſoms there in July, being kept in winter under cover. This is a tall upright *ſhrub*, with round, ſtraight, ſmooth *branches*. *Leaves* four or five inches long, and two broad; ſmooth above; paler with hairy ribs, beneath. *Flowers* hairy, axillary, many together, on hairy ruſty *ſtalks*. *Petals* broad at the baſe. *Stigma* ſlightly three-cleft.

24. R. *glandulofus*. Madeira Buckthorn. Ait. n. 12. Willd. n. 22. Venten. Malmaiſ. t. 34.—Leaves ovate, bluntly ſerrated, ſmooth; glandular at the baſe. Stem erect. Flowers racemoſe. Style in three deep ſegments.—Native of Madeira, and the Canary iſlands. Introduced at Kew, by Mr. Maſſon, in 1785. This has the habit of an *Ilex* or *Phillyrea*. The *leaves* are dark green, ſmooth, two inches long, more or leſs, ovate, pointed, rather diſtantly ſerrated, marked on the upper ſide, near the baſe, with two or three glandular ſpots. *Flowers* yellowiſh, numerous, on ſmooth, racemoſe axillary *ſtalks*. *Stamens* twice as long as the *petals*. *Style* deeply three-cleft. *Stigmas* ſimple. We know nothing of the *fruit*.

25. R. *ellipticus*. Oval-leaved Jamaica Buckthorn. Ait. n. 13. Willd. n. 23. Swartz Ind. Occ. v. 1. 497. (R. n. 1; Browne Jam. 172. t. 29. f. 2. Ceanothus reclinatus; L'Herit. Sert. Angl. 6.)—Leaves elliptical, acute, entire; rather villous beneath. Flowers axillary, ſomewhat umbellate. Style in three deep ſegments. Berry dry.—Native of buſhy places on the mountains of Jamaica. Miller cultivated it in the ſtove at Chelſea in 1758. *Aiton*. *Stem* forming a ſmall tree, with ſpreading or dependent *branches*. *Leaves* two or three inches long, thin, downy on the veins beneath. *Flowers* greeniſh-white. The *fruit* ſeems, by Swartz's deſcription, a dry berry, like that of ſome other ſpecies of *Rhamnus*, and not the valvular capſule of a *Ceanothus*, though, when quite ripe and dried, it ſplits into ſix parts, as we find it in Browne's ſpecimen. The *petals* however are oppoſite to the *ſtamens*.

26. R. *prinoides*. Winter-berry-leaved Buckthorn. L'Herit. Sert. Angl. 6. t. 9. Willd. n. 24. Ait. n. 14. (R. celtifolius; Thunb. Prodr. 44. Celtis foliis ſubrotundis dentatis, flore viridi, fructu luteo; Burm. Afr. 242. t. 88.)—Leaves ovate, ſerrated, ſmooth. Stem erect. Flower-ſtalks ſimple. Style ſlightly three-cleft. Flowers polygamous.—Native of woods at the Cape of Good Hope, where it bloſſoms in September; as is the caſe in England, where this ſhrub was firſt cultivated by Robert Edward, lord Petre. Its habit is that of a *Prinos*, or *Phillyrea*. The *leaves* are from one to two inches long, pointed; ſhining above; paler beneath; ſmooth, except occaſional hairineſs at the origin of each vein. *Flowers* on ſimple, ſlender, axillary *ſtalks*, ſeveral together. *Petals* narrow. This ſpecies, except in its *infloreſcence*, and the want of glands on the *leaves*, bears a conſiderable reſemblance to the *glandulofus*.

27. R. *myſtacinus*. Wiry Buckthorn. Ait. n. 15. Willd. n. 25.—Leaves heart-ſhaped, entire. Stem climbing with tendrils. Flowers in axillary umbels. Stigma three-cleft.—Said to be a native of Abyſſinia; at leaſt it was brought to Kew, in 1775, by the celebrated traveller Mr. Bruce. It is kept in the ſtove, and blooms in November. The *ſtem* is weak, climbing to a conſiderable extent, by means of ſimple ſolitary axillary *tendrils* from the upper part of the branches. *Leaves* an inch long, rather downy beneath, obtuſe with a ſmall point, on very ſhort *footſtalks*. *Flowers* greeniſh-white. *Germen* immerſed in a ſnow-white glandular *receptacle*, filling the tube of the *calyx*. As nothing is known of the *fruit*, this plant may poſſibly prove of the genus *Zizyphus*, to which it ſeems moſt akin in habit.

28. R. *alnifolius*. Alder-leaved American Buckthorn. L'Herit. Sert. Angl. 5. Willd. n. 26. Ait. n. 16.—Leaves obovate, pointed, ſerrated, ſmoothiſh, opaque; reticulated beneath. Flowers hermaphrodite. Stem erect.—Native of Pennſylvania, from whence we have a ſpecimen, communicated by the Rev. Dr. Muhlenberg. It has much the aſpect of *R. alpinus*, but the *leaves*, as l'Heritier obſerves, are leſs ſhining, and more reticulated; they ſeem to us more tapering at the baſe, and not at all heart-ſhaped.

29. R. *ſphæroſpermus*. Clear-berried Buckthorn. Swartz Ind. Occ. v. 1. 499. Willd. n. 27.—Leaves oblong, ſerrated, ſmooth. Stem erect. Flowers in axillary cluſters. Style three-cleft. Berry nearly globular, pellucid.—Native of buſhy hills in the more temperate parts of Jamaica, flowering in Auguſt.—A ſmall tree, ten to fifteen feet high, with

 ſpread-

ſpreading *branches*. *Leaves* pointed, finely veined. *Cluſters* many-flowered, the length of the *footſtalks*. *Flowers* ſmall, yellowiſh-green. *Style* very ſhort. *Berry* the ſize of a ſmall pepper-corn, either quite globular, or obſcurely three-lobed, pellucid, pale green, with one or three ſeeds. It ripens in October.

30. R. *hybridus*. Mule Buckthorn. L'Herit. Sert. Angl. 5. Willd. n. 28.—"Leaves oblong, pointed, ſerrated, ſcarcely perennial. Stem erect. Flowers male and female on the ſame tree."—L'Heritier deſcribes this as having ſprung up in a garden, from ſeeds of *R. alpinus* impregnated by *R. Alaternus*, and partaking of the nature of both parents.

31. R. *Alaternus*. Common Alaternus. Linn. Sp. Pl. 281. Willd. n. 29. Ait. n. 17. (Alaternus 1 et 2; Clu. Hiſt. v. 1. 50. Ger. Em. 1398.)—Leaves ovate, ſerrated, coriaceous, ſmooth. Stem erect. Flowers dioecious, in axillary, ſomewhat compound, bracteated cluſters. Stigma in three deep ſegments.—Native of the ſouth of Europe. A hardy evergreen *ſhrub* in our gardens, flowering in the ſpring. The *leaves* are about an inch long, of a ſhining yellowiſh-green, and of a thick rigid texture. *Flowers* copious, yellowiſh. *Berries* dark purple, with two or three *ſeeds*.

The 30th ſpecies of Willdenow, *R. carpinifolius*, adopted from Pallas's Fl. Roſſ. t. 60, is, we believe, the ſame tree with *Ulmus nemoralis*, Willd. Sp. Pl. v. 1. 1326, or at leaſt of the ſame genus. See Ulmus.

Sect. 3. *Branches armed with prickles.*

32. R. *capenſis*. Prickly Cape Buckthorn. Thunb. Prodr. 44. Willd. n. 31.—"Prickles ſolitary. Leaves ovate, notched or entire, ſmooth. Umbels axillary."—Found by Thunberg, at the Cape.

33. R. *circumſciſſus*. Prickly Eaſt-Indian Buckthorn. Linn. Suppl. 152. Willd. n. 32.—Prickles ſolitary, hooked. Leaves obovate, abrupt, emarginate, entire, ſmooth. Umbels axillary.—Found by Koenig, in the Eaſt Indies. *Branches* angular. *Prickles* numerous, ſtrong. *Leaves* almoſt an inch long, and nearly as broad. *Umbels* many-flowered. *Style* ſimple, ſhort, permanent. Baſe of the *calyx* cup-like after the limb is fallen.

Rhamnus, in *Gardening*, furniſhes plants of the tree and ſhrub kinds, of which the ſpecies cultivated are; the purging buckthorn (R. catharticus); the pubeſcent rhamnus, or buckthorn redwood (R. colubrinus); the alder buckthorn, or berry-bearing alder (R. frangula); the common Chriſt's-thorn (R. paliurus); the common alaternus (R. alaternus); the blunt-leaved buckthorn (R. jujuba); the pointed-leaved buckthorn (R. œnoplia); the ſhining-leaved buckthorn, or common jujube (R. zizyphus); and the Syrian Chriſt's-thorn (R. ſpina Chriſti).

It is found that the juice of the unripe berries, in the firſt ſort, has the colour of ſaffron, and is uſed for ſtaining maps or paper, being ſold under the name of French berries: the juice of the ripe berries, mixed with alum, is the ſap-green of the painters; but if the berries be gathered late in the autumn, the juice is purple. The bark affords a beautiful yellow dye.

In the third ſort, the berries gathered before they are ripe, dye wool green and yellow; when ripe, blue-grey, blue, and green. The bark dyes yellow, and with preparations of iron, black.

There are two varieties of this ſort, the broad-leaved, which has larger and rougher leaves; it grows naturally on the Alps: and the dwarf or round-leaved, which is of humble growth, ſeldom riſing above two feet high; it grows on the Pyrenees.

The fifth is a native of the ſouth of Europe, and of Barbary. The freſh branches or young ſhoots, with the leaves, will dye wool a fine yellow. It flowers about April. And there are varieties with variegated leaves, commonly called bloatched phillyrea by the nurſerymen; and with the leaves ſtriped with white and with yellow, called ſilver and gold-ſtriped alaternus. The latter has the leaves much longer and narrower, and the ſerratures on the edges much deeper: this ſhoots its branches more erect, forms a handſomer buſh, and is equally hardy. It is likewiſe obſerved, that the phillyrea is ſometimes different; and according to ſome, there are alſo the large-growing, the ſmall-growing, the broad-leaved, the narrow-jagged-leaved, the yellow-ſtriped jagged-leaved, the white-ſtriped jagged-leaved: all which are confounded with the alaternus, by ſuch perſons as are not botaniſts; but they may eaſily be diſtinguiſhed by the poſition of their leaves, which are alternate in this, but placed oppoſite by pairs in that. And it is ſuppoſed, that the alaternus was much more in requeſt formerly than at preſent, having been planted againſt walls in court-yards to cover them, as alſo to form evergreen hedges in gardens; for which purpoſe it is very improper, as the branches ſhoot very vigorouſly, and being pliant, are frequently diſplaced by the wind; in winter, when much ſnow falls in ſtill weather, the weight of it often breaks the branches; theſe hedges muſt alſo be clipped three times in a ſeaſon to keep them in order, which is both expenſive and occaſions a great litter in a garden.

The fruit, in the eighth ſort, is ſold in the market at Canton during the autumn. In Italy and Spain it is ſerved up at the table in deſerts during the winter ſeaſon, as a dry ſweetmeat.

And the common or cultivated jujube, according to Miller, has a woody ſtalk, dividing into many crooked irregular branches, armed with ſtrong ſtraight thorns, ſet by pairs at each joint; the leaves are two inches long and one broad, ſlightly ſerrate, on ſhort footſtalks; the flowers are produced on the ſide of the branches, two or three from the ſame place, ſeſſile, ſmall and yellow: the fruit oval, the ſize of a middling plum, ſweetiſh and clammy, including a hard oblong ſtone, pointed at both ends.

The wild jujube has ſlender woody ſtalks, which ſend out many weak branches, covered with a greyiſh bark, and armed with ſpines in pairs, one longer and ſtraight, the other ſhort and recurved; the leaves ſmall, oval, veined, half an inch in length and breadth, and ſeſſile. It is found about Tunis in Africa.

Method of Culture.—The firſt, third, and fourth ſorts may be increaſed by ſeeds, layers, and ſometimes by cuttings; the ſeeds ſhould be ſown in autumn as ſoon as ripe, on a bed of light earth, and ſlightly raked in: the plants moſtly appear in the following ſpring, and when they have had a year or two's growth, they ſhould be planted out in nurſery-rows, to have two or three years more growth, when they may be finally ſet out where they are to ſtand.

It may be noticed that the layers ſhould always be made from the young ſhoots, and be laid down in the autumn, in the uſual way, giving a little twiſt or nick at the time in the bark, at a joint. They moſtly become well rooted in twelve months afterwards.

Cuttings of the firſt and third ſorts may be made from the young twigs, and be planted in rows in the autumn, in a bed of good earth, when moſt of them will ſucceed and grow well.

And all the evergreen or alaternus kinds may be raiſed from ſeeds and by layers. The plain ſorts ſucceed in both methods, but the variegated ſorts only with certainty by layers, well laid down.

And

And the feeds fhould be put into the ground in the early autumn in the fame manner as above; and the layers laid down in the autumn as in the other kinds of plants.

All the other fpecies may be raifed by fowing the ftones of the fruit in pots in fpring, plunging them in a moderate hot-bed. When the plants have attained fome growth they fhould be removed into feparate pots, and be managed as other tender plants. They alfo fucceed by fuckers from the roots and layers, as in the above forts. And the fixth and eighth forts may be placed in the greenhoufe, and the others in the ftove.

Thefe are all ornamental plants; the hardy forts for the pleafure-ground, and the more tender forts for the greenhoufe and ftove, among other potted plants of thefe departments.

RHAMNUS *catharticus*, or *fpina cervina, purging buckthorn*, in the *Materia Medica*. The fruit or berries of this fhrub, which have been long received into the materia medica, are about the fize of a fmall pea, and, when ripe, of a fhining black colour; they contain a pulpy deep green juice, called by the French "verd de veffie," or SAP-*green* (which fee), which has a faint unpleafant fmell, and a bitterifh, acrid, naufeous tafte; they operate brifkly by ftool, and hence the plant derives the trivial name "catharticus:" their purgative effects are conftantly accompanied with confiderable thirft, and drynefs of the mouth and throat, and frequently with fevere griping of the bowels, efpecially unlefs fome diluting liquor be plentifully drunk immediately after taking them. The dofe is faid to be about 20 of the frefh berries in fubftance; twice or thrice that number in decoction; a drachm or a drachm and a half of the dried berries; an ounce of the expreffed juice; or half an ounce of the rob or extract, obtained by infpiffating the juice. The juice made into a fyrup is the officinal preparation, and in this ftate it has been generally preferred by phyficians, who found that in dofes of one ounce or two it proved a very powerful purgative; and was therefore much employed as a hydragogue. Few patients, however, are able to bear a frequent repetition of this medicine; and even Sydenham, who was partial to the purgative treatment of hydropical difeafes, found that other cathartics more effectually anfwered this purpofe. At prefent it is rarely prefcribed, except in conjunction with other medicines of this clafs. Lewis's Mat. Med. Woodville's Med. Bot.

RHAMNUSIA, in *Mythology*, an appellation given to Nemefis, on account of her celebrated ftatue at Rhamnus, in Attica, which has been generally afcribed to Phidias. Pliny, however, gives the honour of it to Agoracritus, a fcholar of Phidias, who, as he fays, had defigned it for a Venus; but feeing one preferred to it, which was executed by Alcamenes, another fcholar of the fame mafter, fold his to the Rhamnufians, on condition that they would only take it for a ftatue of Nemefis, whence fhe gained the name of Rhamnufia. See NEMESIS and RHAMNUS.

RHANDÆ, in *Ancient Geography*, a people of Afia, in Drangiana, on the confines of Afia. Ptolemy.

RHANTERIUM, in *Botany*, fo named by Desfontaines, from ῥαντήριον, *a kind of brufh for fprinkling water*, like that ufed in Catholic churches; the down, or crown, of the feed having a fimilar form.—Desfont. Atlant. v. 2. 291. Willd. Sp. Pl. v. 3. 2105.—Clafs and order, *Syngenefia Polygamia-fuperflua*. Nat. Ord. *Compofitæ difcoideæ*, Linn. *Corymbiferæ*, Juff.

Gen. Ch. *Common Calyx* imbricated, nearly cylindrical; fcales lax, recurved. *Cor.* compound, radiated; florets of the difk numerous, equal, funnel-fhaped, five-cleft, erect, all perfect; thofe of the radius few, ligulate, three-toothed, recurved, female. *Stam.* in the perfect florets five, awl-fhaped, fhort; anthers fimple, united into a five-toothed cylinder. *Pifl.* Germen in all the florets inverfely conical, furrowed; ftyle thread-fhaped, the length of the ftamens; ftigmas two, club-fhaped. *Peric.* none, except the permanent calyx. *Seeds* of all the florets the fhape of the germen; thofe of the difk crowned with from four to fix briftles, thickened and feathery at the top; thofe of the radius naked. *Recept.* flat, chaffy; fcales acute, hollowed on one fide.

Eff. Ch. Receptacle chaffy. Seed-down of about five briftles, feathery at the top. Calyx cylindrical, imbricated. Seeds of the radius naked.

1. R. *fuaveolens*. Desfont. Atlant. v. 2. 291. t. 240.—Found by Desfontaines on the fandy fea-coaft, near Sfax, in the kingdom of Tunis. *Root* perennial. *Stem* erect, much branched, round, leafy, one or two feet high. *Branches* flender, downy, ftriated, often entangled together. *Leaves* fcattered, feffile, three quarters of an inch long, lanceolate, acute, ftrongly ferrated, either fmooth or downy; the upper ones fmaller, linear and entire. *Flowers* terminal, folitary, refembling thofe of feveral of the fmaller-flowered American Afters, except in being entirely yellow. This plant flowers in fummer. The bruifed leaves have a fragrant fmell.

RHAPHANEÆ, in *Ancient Geography*, a town of Afia, in Syria, placed by Ptolemy between Epiphania and Anteradus.

RHAPHIS, in *Botany*, fo called from ῥαφίς, *a needle*, or *awl*, becaufe of the long needle-like awn of the female flowers.—Lour. Cochinch. 552.—Clafs and order, *Monœcia Triandria*. Nat. Ord. *Gramina*.

Gen. Ch. Male flowers two, ftalked, in one common involucrum. *Cal.* Glume fingle-flowered, of two awl-fhaped, coloured, beardlefs, nearly equal valves. *Cor.* Glume of two lanceolate, membranous, fringed, beardlefs valves, fhorter than the calyx. *Stam.* Filaments three, fhort; anthers oblong.

Female flower folitary, in the fame fhort, one-leaved, hairy involucrum, feffile, below the male flowers. *Cal.* as in the male, but fhorter. *Cor.* Glume of two valves, nearly equal to the calyx; one of them furnifhed with a longifh, very fharp awn. *Pifl.* Germen ovate; ftyles two, fhort; ftigmas feathery. *Peric.* none, except the permanent glumes. *Seed* folitary, oblong, compreffed.

Eff. Ch. Involucrum of one leaf, three-flowered. Male, Calyx of two valves, coloured. Corolla of two fringed valves.

Female, Calyx like the male. Corolla of two valves: one of them awned. Styles two. Seed one, oblong.

1. R. *trivialis*. (Gramen aciculatum, Cuffu Cuffu; Rumph. Amboin. v. 6. book 10. chap. 8. t. 5. f. 1. Co may of the Cochinchinefe.)—A very common grafs in China and Cochinchina, growing by road fides, and proving very troublefome on account of its feeds, which ftick into the clothes of paffengers, and cannot be fhaken out. Rumphius fpeaks of it as equally common in the iflands of the Eaft Indies. The *root* is annual, creeping. *Stem* a foot high, erect, round, flender, fmooth, fcarcely branched, almoft leaflefs, except at the bafe. *Leaves* nearly all radical, feffile, fhort, lanceolate, clafping the lower part of the ftem. *Panicle* fimple, folitary, terminal, conical, lax; its branches long, ftraight, afcending. Linnæus erroneoufly cites the above fynonym of Rumphius, under his *Panicum colonum*, a widely different plant.

Mr. Brown, in Prodr. Nov. Holl. v. 1. 199, fuggefts that the above plant of Loureiro and Rumphius ought to be referred

referred to the genus *Holcus*, along with all the panicled ſpecies of *Andropogon;* and he remarks, on the authority of a ſpecimen from the author, in ſir J. Banks's collection, that it ſeems ſcarcely diſtinct from *Andropogon acicularis* of Retzius, Willd. Sp. Pl. v. 4. 906, for which indeed the ſame ſynonym of Rumphius is quoted.

RHAPIS, ſo called by the younger Linnæus, from ῥαπις, *a rod*, probably in alluſion to the name it has obtained from Europeans in China, of Ground Ratan; but we know not preciſely how that name applies to the plant.—Ait. Hort. Kew. ed. 1. v. 3. 473. ed. 2. v. 5. 473. Schreb. 772. Willd. Sp. Pl. v. 4. 1093. Mart. Mill Dict. v. 4.—Claſs and order, *Polygamia Monoecia;* rather *Hexandria Monogynia*. Nat. Ord. *Palmæ*.

Gen. Ch. *Cal.* Perianth inferior, minute, rigid, of one leaf, in three deep, broad, concave, permanent ſegments. *Cor.* of one petal, larger than the calyx, in three deep, erect, concave, equal ſegments, deciduous. *Stam.* Filaments ſix, awl-ſhaped, nearly as long as the corolla; anthers roundiſh, two-lobed. *Piſt.* Germen ſuperior, three-lobed; ſtyle ſhort, awl-ſhaped; ſtigma obtuſe. *Peric.* Berry roundiſh-ovate. *Seed* ſolitary, roundiſh, bony.

Obſ. The flowers are often polygamous or dioecious.

Eſſ. Ch. Calyx three-cleft. Corolla of one petal, three-cleft. Berry with one large, roundiſh, bony ſeed.

1. R. *flabelliformis*. Creeping-rooted Palmetto, or Ground Ratan. Ait. n. 1. Willd. n. 1. Sm. Tour, v. 1. 12. and 279. Jacq. Hort. Schoenbr. v. 3. 36. t. 316. Curt. Mag. t. 1371. (Chamærops excelſa; Thunb. Jap. 130.)—Leaves palmate, plaited; their plaits and margins ſharply toothed.—Native of China and Japan. *Root* creeping, with numerous long ſtraight fibres. *Stem* riſing to a great height in its native country; in our ſtoves it has not yet reached above ſix or eight feet; it is clothed with a looſe network, formed of the baſes of the decayed leaf-ſtalks. *Leaves* ſtalked, divided almoſt to the baſe into many plaited oblong lobes, a ſpan long, rough at the ribs and edges with prickly teeth. *Flowers* moſtly dioecious, yellow, in panicled cylindrical ſpikes. *Berry* ſmall, dark purple, ſweet with a bitteriſh flavour, barely eatable.

2. R. *acaulis*. Swamp Palmetto. Willd. n. 2. Ait. n. 2. (Corypha minor; Jacq. Hort. Vind. v. 3. 8. t. 8. Sabal Adanſoni; Gawl. in Curt. Mag. t. 1434. Purſh v. 1. 239.)—Leaves palmate, ſtriated, entire, ſmooth.—Native of the ſea-coaſt of Carolina and Georgia, flowering in Auguſt. Of humble growth, having no leafy *ſtem*. The *leaves* are longer and narrower than in the foregoing, quite ſmooth and entire. *Flowers* numerous, greeniſh-white, in numerous, cylindrical, lax, panicled ſpikes, ſupported by a ſtraight, round common ſtalk, taller than the foliage. *Berry* the ſize of a ſmall pea, black, ſweetiſh. *Jacq.*

3. R. *arundinacea*. Simple-leaved Palmetto. Ait. n. 3. Willd. n. 3.—Leaves in two deep, acute, plaited lobes; roughiſh at the edges.—Native of Carolina. A greenhouſe plant at Kew, flowering in September.

The orthography of the generic name in Curt. Mag. 1434, is remarkably confuſed, and ſeems to have miſled Mr. Purſh to print it *Raphis*, citing Willdenow without examination.

RHAPONTICUM. See RHA.

RHAPONTICUM, a medicinal root, in form reſembling rhubarb, and nearly of the ſame virtues.

It was called *rhaponticum*, q. d. *root of Pontus;* becauſe chiefly produced in the country of Pontus in Aſia.

It is the root of a plant, which is a ſpecies of the *rheum*, with ſmooth roundiſh leaves, and ſomewhat channelled pedicles. It grows wild on the mountain Rhodope in Thrace, from whence it was brought into Europe by Alpinus about the year 1610; it bears the hardeſt winters of this climate. The root of this plant, ſays Dr. Lewis, which appears to have been the true rhubarb of the ancients, is confounded by ſome with the modern rhubarb, though conſiderably different from that root in appearance, as well as in quality. The rhapontic is of a duſky colour on the ſurface, and of a looſe ſpongy texture; more aſtringent than rhubarb, and leſs purgative: in this laſt intention, two or three drachms are required for a doſe. Lewis's Mat. Med.

It has, however, been much controverted, whether the rhaponticum of the ancients, and the rhubarb of the moderns, be one and the ſame plant: the reaſoning on both ſides may be ſeen in the appendix to the ſecond volume of John Bauhin's Hiſtory of Plants. See RHUBARB.

RHAPPHA, in *Ancient Geography*, a town of India, on the other ſide of the Ganges, among the people called Gangani. Ptolemy.

RHAPSA, a town of Aſia, in the interior of Media.

RHAPSODI, Ῥαψῳδοι, RHAPSODISTS, in *Antiquity*, perſons who made a buſineſs of ſinging or reciting pieces of Homer's poems.

Cuper informs us, that the rhapſodi were clothed in red, when they ſung the Iliad; and in blue, when they ſung the Odyſſey.

They performed on the theatres; and ſometimes ſtrove for prizes, in conteſts of poetry, ſinging, &c.

After the two antagoniſts had finiſhed their parts, the two pieces, or papers they were written in, were joined together again; whence the name, *viz.* from ῥαπτω, *ſuo, I join together*, and ῳδη, *ode, ſong.*

But there ſeem to have been other rhapſodi of higher antiquity than theſe; people who compoſed heroic poems, or ſongs in praiſe of heroes and great men, and ſung their own compoſitions from town to town, for a livelihood; of which profeſſion, it is ſaid, was Homer himſelf.

Hence, ſome critics, inſtead of the former origin, derive the word rhapſodiſt from ῥαβδῳ αδειν, *to ſing with a laurel-rod in the hand*, which, it ſeems, was the badge of the primitive rhapſodi.

Philochorus, again, derives the word from ῥαπτειν τας ῳδας, *q. d.* συντιθεναι, *to compoſe ſongs or poems;* as if they were the authors of the poems they ſung. This opinion, to which Scaliger inclines, reduces theſe rhapſodi to the ſecond kind.

In effect, it is probable, that they were all of the ſame claſs, whatever diſtinction ſome authors may imagine among them; and that their buſineſs was to ſing or rehearſe poems, either of their own, or other people's compoſition, as might beſt ſerve their purpoſe, which was gaining a pecuniary advantage by them. So that we do not apprehend it any injury to them, to ſet them on the foot of our ballad-ſingers; ſome of whom may probably pen their own ditties. After Homer's time, it is no wonder they confined themſelves altogether to his pieces, for which the people had the utmoſt veneration; nor is it ſurpriſing, that they ſhould erect ſtages, &c. and diſpute the point of recitation in fairs and markets.

The import of the word rhapſodiſt underwent ſeveral changes in antiquity: it was firſt appropriated to bards, who ſung their own verſes from town to town, or at the tables of the great; in this ſenſe Homer was called a rhapſodiſt. It was next beſtowed on thoſe who ſung the verſes of Homer on the ſtage, uſually for a prize, allotted to the beſt performer of them; and, laſtly, to ſuch ſingers of centos, as have been juſt deſcribed. A rhapſody, in modern language, conveys no other meaning than that of an incoherent jumble of ideas. This ſenſe of the word undoubtedly took its riſe from the notorious folly and abſurdity of the rhapſodiſts, in their rapturous comments upon their favourite poets; for they undertook to explain, as well as to recite. Hence it is that in Suidas, the word ῥαψῳδία is defined by φλυαρία, *nonſenſe.*

RHAPSODOMANCY, ῥαψῳδομαντεία, an ancient kind of divination performed by fixing on a paſſage of a poet at hazard, and reckoning on it as a prediction of what was to come to paſs.

There were various methods of practiſing this rhapſodomancy. Sometimes they wrote ſeveral verſes or ſentences of a poet on ſo many pieces of wood, paper, or the like; ſhook them together in an urn; and drew out one, which was accounted the lot.

Sometimes they caſt dice on a table, on which verſes were written; and that on which the die lodged, contained the prediction.

A third manner was by opening a book, and pitching on ſome verſe, at firſt ſight. This method they particularly called the *ſortes Præneſtinæ*, and afterwards, according to the poet thus made uſe of, *ſortes Homericæ, ſortes Virgilianæ*, &c.

RHAPSODY, ῥαψῳδία, in *Antiquity*, a diſcourſe in verſe, ſung or rehearſed by a rhapſodiſt.

Others will have rhapſody properly to ſignify a collection of verſes, eſpecially thoſe of Homer; which, having been a long time diſperſed in pieces and fragments, were at length, by Piſiſtratus's order, digeſted into books, called rhapſodies; from the Greek ῥάπτω, *ſuo, I ſew*, and ᾠδὴ, *ſong.*

Hence, among the moderns, rhapſody is alſo uſed for an aſſemblage of paſſages, thoughts, and authorities, raked together from divers authors, to compoſe ſome new piece. Lipſius's Politics make ſuch a rhapſody, in which there is nothing of the author's own but conjunction and particles.

RHAPTE, in *Ancient Geography*, the metropolis of the Ethiopians, near the river Raptus. Steph. Byz.

RHATOSTATHIBIUS, or, as Baxter thinks it was originally written, *Retoſtaubius*, a river of the iſle of Albion, (England,) on the weſtern ſide, the mouth of which is placed by Ptolemy between that of the Tobius and the eſtuary of Sabrina. This is the river Wye, and its ancient name is derived from "Rot in Tav," the courſe of a river.

RHATTA, a town of Aſia, in Babylonia, in the vicinity of Chiriphe. Ptolemy.

RHAUCUS, a town of the iſland of Crete. Steph. Byz.

RHAVENA, a prefecture of Aſia, along the Euphrates. Ptolemy places in it ſix towns on the banks of the Euphrates, and four in the interior of the country.

RHAVIUM, a river of Hibernia, the mouth of which is placed by Ptolemy between the promontory "Boreum" and the town "Magnata."

RHAUNEM, in *Geography*, a town of France, in the department of the Seine, and chief place of a canton, in the diſtrict of Birkenfeld. The place contains 547, and the canton 5886 inhabitants, in 35 communes.

RHAUNETI, in *Ancient Geography*, a town of Arabia Felix, on the Arabian gulf, between the town "Phœnicum" and the extremity of this Cherſoneſus. Ptolemy.

RHAURARIS, a river of Gallia Narbonenſis, according to Strabo. This river is called "Araurius" by Ptolemy, and "Arauraris" by Pomponius Mela.

RHAUZIUM, the metropolis of Dalmatia, according to Cedrenus and Curopalata.

RHAW, George, in *Biography*, a learned bookſeller and muſician of Wittemberg, born in 1494. In 1531 appeared an "Enchiridion utriuſque Muſicæ Practicæ, ex variis Muſicorum Libris congeſtum," in 8vo. And in 1538 he not only publiſhed "Select Harmony for four Voices," conſiſting of two Latin Paſſiones, the one by John Galliculus, and the other by Jacob Otrecht, with maſſes, lamentations of Jeremiah, and motets by John Walther, Lewis Senfels, Simon Cellarius, Benedict Dux, Eckel, Lemlin, Stoel, and Henry Iſaac, to which Melancthon furniſhed him with a Latin preface; but in 1544 publiſhed, in oblong quarto, 123 German ſacred ſongs, of four and five parts, for the uſe of ſchools. Prefixed to the ſecond part of this publication, containing eccleſiaſtical hymns, ſet by ſixteen different German compoſers, there is a print of the editor, Geo. Rhaw, Typographus, Wittemb. anno ætatis ſuæ LIV.

RHAZES, one of the oldeſt and moſt diſtinguiſhed of the Arabian phyſicians, was born at Rei, in the province of Choraſan, about the year 852. There was a ſchool in his native town, at which he received his early education; but he is ſaid not to have commenced the ſtudy of medicine till ſomewhat late in life, having given up his time much to the cultivation of muſic. After he was thirty years of age, he removed to Bagdad, and then he turned his attention to philoſophy, and afterwards to phyſic. He became, however, indefatigable in his application, and was continually occupied in obſerving, reading, and writing, until he obtained the higheſt reputation; and he was ſelected out of a hundred eminent phyſicians, who were then reſident at Bagdad, to ſuperintend the celebrated hoſpital of that city. The hiſtorians conſidered him as the Galen of the Arabians; and from his long life and conſtant practice, during which he paid the moſt aſſiduous attention to the varieties of diſeaſe, he obtained the appellation of the experimenter, or the experienced. He was ſaid alſo to be profoundly ſkilled in all the ſciences, eſpecially in philoſophy, aſtronomy, and muſic. He travelled much in purſuit of knowledge, and made frequent journies into Perſia, his native country, and was much conſulted by ſeveral princes, particularly by Almanzor, the chief of Choraſan, with whom he frequently correſponded, and to whom he dedicated ſeveral of his writings. Abi Oſbaia enumerated two hundred and twenty-ſix treatiſes compoſed by Rhazes, among which the *ten* books, addreſſed to his patron Almanzor, are mentioned, and therefore are doubtleſs genuine, although Haly Abbas, who has given an account of him and his works, has not noticed them. This work Rhazes deſigned as a complete body of phyſic, and it may be deemed the great magazine of all the Arabian medicine; the ninth book, indeed, which treats of the cure of diſeaſes, was in ſuch general eſtimation for ſeveral centuries, that it was the text-book of the public ſchools, and was commented upon by the moſt learned profeſſors. Nevertheleſs, like the reſt of the Arabian writings, it contains very little more than the ſubſtance of the works of the Greeks, from whom the Arabians borrowed almoſt all their medical knowledge. They have, indeed, and Rhazes in particular, given the firſt diſtinct account of *the ſmall-pox*, a peſtilential malady which the Greeks have no where accurately deſcribed, and which is, therefore, generally inferred to have been unknown among that people. This is queſtionable; but, at all events, the firſt ſpecific account of the ſmall-pox is to be found in the works of Rhazes. He was the author, alſo, of the firſt treatiſe ever compoſed reſpecting the diſeaſes of children. His book on the affections of the joints is intereſting, and contains an account of ſome remarkable cures, effected chiefly by copious blood-letting. He deſcribes the ſymptoms of hydrophobia very well; and alfo fome difeafes peculiar to eaftern countries, as the ignis perficus, vena medinenfis, &c.; and he firft noticed the difeafe called fpina ventofa. Rhazes had the reputation of being a fkilful alchemift; the art of chemiftry, in fact, originated with the Arabians, and Rhazes is the firft, as Dr. Freind has fhewn, who mentions the ufe of chemical preparations in medicine. He has a chapter on the qualifications of a phyfician; and a fingular tract on quacks and impoftors, in which he has pourtrayed that clafs of pretenders to the life; and his detail of their pretenfions fhews that they were at leaft as numerous, and ingenious in their contrivances of cheatery, as in more recent times.

Rhazes lived to the age of eighty, and loft his fight: he died in the year 932. His works that have come down to us, through the medium of tranflations in Latin, are, 1. A fort of common-place book, entitled "Continens," or "Libri Continentes." 2. A much more perfect work, the "Libri Decem, ad Almanforem," publifhed at Venice, 1510. 3. Six books of aphorifms, publifhed under the title of "Liber de Secretis, qui Aphorifmorum appellatur," Bononiæ, 1489. 4. A tract on the fmall-pox, often tranflated, and printed with the title of "De Peftilentia;" the beft tranflation is by Channing, London, 1766. Freind's Hift. of Phyfic. Eloy Dict. Hift. de la Med.

RHAZUNDA, in *Ancient Geography*, a town of Afia, in the interior of Media, between "Sanais" and "Veneca," according to Ptolemy.

RHEA, a town of Afia, in Margiana, according to Ptolemy.

Rhea, in *Mythology*, one of the titles of Cybele, derived from ῥέω, *I flow*, on account of that abundance of benefits which fhe difpenfes.

Rhea was, according to Diodorus Siculus, one of the eight great divinities of Egypt; the other feven being the Sun, Saturn or Chronos, Jupiter, Juno, Vulcan, Vefta, and Mercury. Chronos, fays this hiftorian, having married Rhea, became, according to fome, the father of Ofiris and Ifis, and, according to others, of Jupiter and Juno. The children of Rhea, by Saturn, were, according to fabulous hiftory, Vefta, Ceres, Juno, Pluto, Neptune, and Jupiter, the father of gods and men; but that god learning from an oracle delivered by Cœlus and Terra, that one of his children fhould dethrone him, devoured them as Rhea brought them forth, which threw her into extreme diftrefs. So that when fhe was near her time of being delivered of Jupiter, fhe confulted her parents to know in what manner fhe might refcue him from the cruelty of his father, and by their advice fhe fecretly withdrew into Crete, where fhe was delivered, and prefented Saturn with a ftone wrapped about with fwaddling clothes, which he fwallowed. Jupiter being grown up, refcued Cœlus from the chains with which Saturn had loaded him; and Cœlus, in return for his fervice, gave him thunder, by which he became the fovereign of gods and men. Rhea was one of the names under which the earth was worfhipped.

Rhea-*Sylvia*, was the mother of Remus and Romulus; and in order to give dignity to their origin, the fable reports that her uncle Amulius got into her cell, and her father Numitor propagated the ftory that the twins fhe brought forth had been begotten by the god of war.

Rhea, in *Ornithology*, a fpecies of the ftruthio or oftrich, the fame bird with the *nhan-duguacu* of the Brafils. See Struthio.

RHEBAN, in *Ancient Geography*, a river of Afia, in Bithynia. According to Arrian, the fource of this river was on mount Olympus, and its mouth in the Euxine fea, near that of Pfillis.

RHECHIUS, a river of Greece, which difcharged itfelf into the fea near Theffalonica. At the mouth of this river Juftinian erected a fort called "Artemifa."

RHEDA, in *Geography*, a town of Germany, the capital of a lordfhip, in the county of Lingen; 10 miles N. of Lipperftadt. N. lat. 51° 47′. E. long. 7° 50′.

Rheda, a town of Holland, in Guelderland, on the Iffel; feven miles N. of Arnheim.

RHEDONES, in *Ancient Geography*, a people of Gaul, in Armorica, according to Cæfar and Ptolemy.

RHEEDIA, in *Botany*, called Vanrheedia by Plumier, in honour of a moft illuftrious promoter of the ftudy of Eaft Indian plants, Henry Van-Rheede Van-Draakenftein, to whofe judgment and munificence, while governor of Malabar towards the latter part of the 17th century, the publication of that fplendid work the *Hortus Malabaricus*, in 12 folio volumes, is owing.—Linn. Gen. 260. Schreb. 348. Mart. Mill. Dict. v. 4. Juff. 258. Lamarck Illuftr. t. 457. (Vanrheedia; Plum. Gen. 45. t. 18.) Clafs and order, *Polyandria Monogynia*. Nat. Ord. *Guttiferæ*, Juff.

Gen. Ch. *Cal.* none. *Cor.* Petals four, feffile, obovate, concave, fpreading. *Stam.* Filaments numerous, thread-fhaped, longer than the corolla; anthers oblong. *Pift.* Germen fuperior, ovate; ftyle cylindrical, the length of the ftamens; ftigma funnel-fhaped. *Peric.* Berry ovate, thin, of one cell. *Seeds* three, very large, ovate-oblong, marked with fimple or branched lines.

Eff. Ch. Petals four. Calyx none. Berry fuperior, with three feeds.

1. R. *lateriflora*. Linn. Sp. Pl. 719. (Vanrheedia folio fubrotundo, fructu luteo; Plum. Ic. 255. t. 257.)—Native of South America. A *tree* known only to Plumier, whofe figure reprefents it with large, oppofite, ftalked, ovate, entire *leaves;* axillary tufts of numerous, rather fmall, *flowers;* and ovate pendulous *fruit*, about two inches long. Juffieu doubts whether the *calyx* be really wanting.

Linnæus does not appear to have ever had a fpecimen of this plant; nor can we account for his ftriking out (in Mant. 401.) the obfervation in his Sp. Pl. for which he has fubftituted, in Syft. Veg., the following defcription, taken from fome Eaft Indian fpecimen, as his original manufcript fhews, and certainly foreign to the true *Rheedia*. "A *tree*, with jointed, compreffed, even, downy *branches*. *Leaves* oppofite, ftalked, lanceolate, entire, fmooth. *Footftalks* fhort, downy. *Flower-ftalks* axillary, about three together, three cleft, three-flowered."

Willdenow has omitted this genus, in its proper place, nor have we difcovered what he has done with it.

RHEGADORA, in *Ancient Geography*, a town of Afia, in Cappadocia.

RHEGIANUM, a town of Lower Mœfia, on the bank of the Danube. Ptolemy.

RHEGIAS, a town of Afia, in Syria: according to Ptolemy it was in Cyrrheftica, between Ariferia and Ruba.

RHEGIUM, or Regium, (*Reggio*), a town of Italy, at the extremity of Brutium, in the ftrait of Sicily. In the time of Dionyfius the tyrant, the inhabitants of Rhegium formed a league againft him, which terminated in a treaty in the year 354. A difference afterwards occurring between them, he befieged the town and took it, after about eleven months, in 365. The conduct of Dionyfius during this fiege was in the higheft degree favage and brutal. Rhegium afterwards became fubject to the Romans; but a legion, encouraged by the example of the Mamertins of Meffina, revolted in 472, and took poffeffion of the city. After ten years' poffeffion, it was befieged by the Romans, and thofe who efcaped the deftruction of the fiege, to the amount of about 300, were carried to Rome, where they were fcourged and beheaded. This city fuffered much from the earthquake that ravaged Calabria; and even in the time of the Romans it was abandoned by its inhabitants, on account of the calamities which it had fuffered; but Cæfar rebuilt it, after having driven Pompey from Sicily. Virgil (l. iii. v. 414, &c.) thus defcribes it:

"Hæc loca vi quondam, et vaftâ convulfa ruinâ
(Tantum Ævi longinqua valet mutare vetuftas)
Diffiluiffe ferant, quam protenus utraque tellus
Una foret; venit medio vi pontus, et undis
Hefperium Siculo latus abfcidit arvaque et urbes
Littore diductas augufto interluit æftu."

RHEGMA, a place of Afia, in Cilicia, at the mouth of the river Cydnus. Strabo.—Alfo, a town of Arabia Felix, on the coaft of the Perfian gulf, in the country of the Anarites. Ptolemy.

Rhegma, formed of ῥήγνυμι, *I break*, a word ufed by the ancients to exprefs any breaking or burfting of a foft part without a wound, but moft frequently for abfceffes breaking inwardly.

RHEID, in *Geography*, a town of France, in the department of the Roer; 2 miles E. of Gladbeck.

RHEIMS. See Reims.

RHEIN, a town of Pruffia, in the province of Natangen, on a lake which communicates with Spirding lake. It has a large fortified caftle, and an inferior court of juftice; 68 miles S.E. of Königfberg. N. lat. 53° 48'. E. long. 21° 42'.

RHEINAU, a town of France, in the department of the Lower Rhine, fituated on the Rhine, and very much reduced by the inundations of the river; 5 miles S. of Strafburg.—Alfo, a town of Switzerland, in the Thurgau, fituated on an ifland formed by the Rhine, with a convent; 5 miles S.S.W. of Schaffhaufen.

RHEINBACH, a river of Saxony, which joins the Loderbach, near Bitterfeld.

Rheinbach, a town of France, in the department of the Rhine and Mofelle, and chief place of a canton, in the diftrict of Bonn. The place contains 1119, and the canton 16,478 inhabitants, in 37 communes.

RHEINBECK, a town of the duchy of Holftein; 10 miles E. of Hamburg.

RHEINBERG, a town of France, in the department of the Roer, and chief place of a canton, in the diftrict of Creveldt; 44 miles N.W. of Cologne. The place contains 1705, and the canton 7166 inhabitants, in 17 communes.

RHEINE, or Reinen, a town of Germany, in the bifhopric of Munfter, on the Embs, near which are fome falt fprings; 22 miles N. of Munfter. N. lat. 52° 21'. E. long. 7° 25'.

RHEINECK, or Rheinegg, a town of Switzerland, and capital of the Rheinthal, fituated on the Rhine, near its confluence with the lake of Conftance, inhabited chiefly by Proteftants; 26 miles S.E. of Conftance.

RHEINFELDEN, a town of Germany, and lately one of the four foreft towns of Auftrian Swabia, on the S. fide of the Rhine, on the oppofite bank of which is a covered way, built like a horn-work, and communicating with the town by means of a bridge; 9 miles E. of Bâle. N. lat. 47° 35'. E. long. 7° 50'.

RHEINFELS. See Rhenfels.

RHEINHAUSEN, a town of Baden, in the circle of the Upper Rhine, on the E. fide of the Rhine; 3 miles S.E. of Spire.

RHEINMAGEN. See Remagen.

RHEINSDORF. See Ronsdorf.

RHEINTHAL, a bailiwic of Switzerland, between the canton of Appenzel and the Rhine, belonging to the nine cantons, about 30 miles long, and from three to eight broad. The country is fertile, and produces excellent wine. The number of inhabitants is about 13,000, who are partly Proteftants and partly Roman Catholics.

RHEINWALD, a valley in the country of the Grifons, about 20 miles long, which takes its name from a branch of the Rhine that paffes through it.

RHEMAN, or Reman, in *Ancient Geography*, a fortified place of Afia, in Mefopotamia, which belonged to the Romans, according to Ammianus Marcellinus.

RHEMBA, in *Hindoo Mythology*, is a character correfponding in many parts to the popular Venus of the Greeks. Like her fhe fprang from the foam of the ocean, when churned by the gods and demons for the purpofe of obtaining the amrita, or beverage of immortality, as noticed under the articles Kurmavatara and Lakshmi. She is fometimes faid to be an incarnation of Lakfhmi, confort of Vifhnu. More correctly, however, fhe is ftationed in the court of Indra, as the chief of his bands of celeftial chorifters, named Apfara, Devangana, Gandharva, &c. The Apfaras, or Upfaras, are the Nereids of the Hindoo Pantheon: having fprung from water, they are called water nymphs, and affift Indra, the Jupiter Pluvius of India, in his regency over aqueous phenomena. (See Upsara.) In the churning procefs above adverted to, thefe fair damfels were produced in extravagant numbers, according to the Ramayana, *viz.* 600 millions! "of refplendent and celeftial form; adorned with glorious ornaments, and endowed with beauty, youth, fweetnefs, and every grace." Thefe interefting offspring of poetical imagination are proverbially elegant and graceful. The three wives of the mortal father of Ramachandra are faid, in the work juft quoted, to be queens, who, "in elegance of form, rivalled the Apfaras." As the chief of thefe damfels of Paradife, the fubject of this article is fometimes ftiled Rhemba-devi, or the goddefs Rhemba.

In Hindoo writings, efpecially in amatory poetics, allufions frequently occur to the Upfaras, who correfpond alfo with the fairies of the Perfians. Many are mentioned by name, Rhemba the ofteneft, Urvafi, Tilotamma, Menaka, &c. (See thofe articles.) Under the name of the laft we have given an inftance of the ufe made by Indra of thefe obfequious fulfillers of his will; for, as well as in the line of finging, dancing, &c. condefcenfions to the Indra-dikas, or the demi-gods, the Apfaras are the fafcinating difturbers of holy men, when engaged in fuch fervent aufterities as threaten the fafety of Indra in his firmamental throne. In explanation of which, it requires to be noticed that Indra was originally a mere mortal; but learning that the throne of heaven was the reward of the man who fhould, with the prefcribed ceremonies, perform one hundred afwamedhas, or facrifices of a horfe, he did fo, and obtained his dominion, and the name of Shatkratu, or he who performs a hundred facrifices. (See Indra.) His throne he retains until another mortal fhall equal or exceed him in this potent ftile of propitiation. He is, therefore, always on the watch; and being all eyes, never fails to difcover aufterc faints while performing their rigid duties; when he either fteals or defiles the horfe intended and fanctified for the next facrifice, or detaches Rhemba or Menaka, or fome other of his damfels of "fafcinating fymmetry of form," who always fucceed in exciting emotions incompatible with the required purity of fuch as afpire to oust Indra from his ethereal throne. See Menaka.

The

The name Apfara is fometimes written *Upfara*, under which latter word fomething farther concerning thefe damfels will be found.

RHENA, in *Geography*, a town of Germany, in the duchy of Mecklenburg; 22 miles W.S.W. of Wifmar. N. lat. 53° 50'. E. long. 11° 10'.

RHENANUS, BEATUS, in *Biography*, a learned German, was born at Rheinac in 1485, and died at Strafburgh in 1547. He was corrector of the prefs for Frobenius, and by that means formed an intimacy with Erafmus. He wrote "A Hiftory of Germany," 4to.; "Illyrici Provinciarum utrique Imperiorum Romano, tam Conftantinopolitano Servientis, Defcriptio," 8vo. He was alfo the editor of Velleius Paterculus, and other works.

RHENEA, in *Ancient Geography*, an ifland of the Ægean fea, in the neighbourhood of that of Delos. Strabo fays that it was deferted, but that it was the place of burial for the inhabitants of Delos; which being deemed facred, it was forbidden to bury the dead in it. The two ifles of Delos and Rhenea are called "Dili or Ifdiles."

Rhenea retains its name, and is denominated alfo Great Delos; it is feparated from the famous ifland of Delos by a ftrait of about 500 toifes. In the middle of this narrow channel are two fhoals, called the Great and the Little Ramateari: the ancient Greeks had confecrated the larger to Hecate or Diana, and called it the ifland of Hecate, or Pfammite. Ships, even men of war, find good anchorage near this ifland. N. lat. 37° 10'. E. long. 25° 15'. See DELOS.

RHENEN, in *Geography*, a town of Holland, in the department of Utrecht, feated on the river Leck; 20 miles N.N.E. of Bois-le-Duc. N. lat. 51° 59'. E. long. 5° 30'.

RHENFERD, JAMES, in *Biography*, a celebrated oriental fcholar, was born at Mulheim, in Weftphalia, in the year 1654. He went through a courfe of academical ftudies at the college of Meurs, a city in the duchy of Cleves, and afterwards travelled for improvement into foreign countries. In 1678, when he was 24 years of age, he accepted an invitation to become rector of the Latin college in the city of Franeker; but upon the condition that, while he held that poft, he fhould be at liberty to deliver lectures on the Oriental languages. He refigned his rectorfhip and removed to Amfterdam, where fome of the moft wealthy families in that city employed him in the capacity of tutor, and he enjoyed, at the fame time, a favourable opportunity for converfing with learned Jews, and improving his knowledge of rabbinical learning. In the year 1683, a vacancy having taken place in the profefforfhip of the Oriental languages and facred philofophy at the univerfity of Franeker, by the removal of the famous Vitringa to the theological chair, M. Rhenferd received an invitation to fill it; which he accepted. M. Rhenferd held this poft nearly thirty years, during which he had the honour of being thrice chofen rector of the univerfity. He died in 1712, when he was in the 59th year of his age. His learning was general and extenfive; but he chiefly excelled in an acquaintance with the Hebrew, including the Rabbinical, the Chaldee, and Syriac. He was author of feveral learned works, among which the following may be mentioned; "De Antiquitate Characteris hodierni Judaici," 1696, 4to.; in which he endeavoured to eftablifh the claim of the prefent Hebrew characters to the higheft antiquity, and to prove that the Samaritan characters were borrowed from the Hebrews; "Comparatio Expiationis anniverfariæ Pontificis maximi in Vet. Teft. cum unica atque æterna Expiationis Chrifti Domini;" "Inveftigatio Præfectorum et Miniftrorum Synagogæ," 1700, 4to.; "Differtationum Theologico-philologicarum de Stylo Novi Teftamenti Syntagma, quo continentur Olearii, Cocceii, &c. de hoc genere Libelli," &c. 1701, 4to.; "Arabarcha, feu, Ethnarcha Judæorum," 1702, 4to.; "De Statuis et Aris, falfis verifque Dei et Hominum Internunciis," in illuftration of Exod. xx. 23, 24, 1705, 4to.; "Obfervationum felectarum ad Loca Hebræa Nov. Teft. partes five Difput. Tres," 1705, 4to. &c. In 1706 he commenced the publication of a work, entitled "Rudimenta Grammaticæ Harmonicæ Linguarum Orientalium, Hebrææ, Chaldaicæ, Syriacæ, et Arabicæ," which he did not live to finifh.

RHENONES, among the ancient Germans, a kind of garment covering the fhoulders and breaft down to the middle. It was either entirely made of fkins, or covered over with them; the long hair of which being outward, proved a good defence againft rain.

RHENUS, in *Geography*. See RHINE.

RHEO-STATICS, is ufed by fome for the ftatics, or the fcience of the equilibrium of fluids.

RHERIGONEUS SINUS, in *Ancient Geography*. See RERIGONIAN *Bay*.

RHESAPHA, a town of Syria, in the Palmyrene, near Cholle. Ptol.

RHESCIPA, or RESCHIPHA, a town of Afia, in Mefopotamia, upon the banks of the Euphrates, between Bethauna and Agamana. Ptol.

RHESINA, a town of Afia, near Mefopotamia, on the river Aboras. Steph. Byz.

RHETICUS, GEORGE JOACHIM, in *Biography*, an excellent German aftronomer and mathematician in the 16th century, and a native of Feldkirk, the chief town of one of the weftern counties of the Tyrolefe, was born in the year 1514. Difcovering early an inclination towards the ftudy of the mathematics, he was initiated in the elements of that fcience at Zurich; whence he removed to the univerfity of Wittemberg: here he took the degree of mafter of philofophy in 1535, and two years afterwards he was made joint profeffor of the mathematics and aftronomy with the famous REINHOLD. (See his article.) While he was daily rifing into reputation by his lectures, he was informed of the hypothefis of Copernicus concerning the revolution of the heavenly bodies; which appeared to him to be fo reafonable, that he determined to refign his profefforfhip, and ftudy the doctrine under the inftructions of its author. Accordingly, in 1539, he left Wittemberg, and went into Pruffia, where he became a difciple of that great man. To the fyftem of Copernicus he foon became an entire convert; and he afterwards affifted his mafter for fome years in his aftronomical labours. In vain did he for a long time urge Copernicus, in common with the other friends of that aftronomer, to favour the world with his grand work, "De Revolutionibus Orbium Cœleftium." At length, the perfuafions of his friends having prevailed upon Copernicus to permit the appearance of his work, the care of editing it was confided to Rheticus, who caufed it to be printed at Nuremberg in 1543, in folio. He now began his very elaborate "Canon Doctrinæ Triangulorum," or canon of fines, tangents, and fecants, to fifteen places of figures, and to every ten feconds of the quadrant: a defign which he did not live to complete. The canon of fines, however, to the fame radius, for every ten feconds, and for every fingle fecond in the firft and laft degree of the quadrant computed by him, was publifhed at Francfort in 1613, folio. Upon the death of Copernicus, who lived only a few hours after he received a copy of his printed work, Rheticus returned to Wittemberg, and was again admitted to his poft of mathematical and aftronomical profeffor. For fome time after

after this he taught the mathematics at Leipsic; and he afterwards left Saxony a second time, and went into Poland. In the year 1576, upon the invitation of a Hungarian nobleman, he went to Cassavia in Hungary, where, in consequence of sleeping in a room recently plaistered, he caught a disorder on his lungs, which proved fatal to him in the 63d year of his age. He composed and published "Ephemerides," according to the doctrine of Copernicus, till the year 1551; "Orationes de Astronomia, Geometria, et Physica," &c.

RHETORIANS, Rhetorii, a sect, in the fourth century, in Egypt, so nominated from their leader Rhetorius.

His distinguishing doctrine, as represented by Philastrius, was, that he approved of all the heresies before him, and taught that they were all in the right. But what Philastrius mentions of him appears so absurd and ridiculous, that St. Augustine, Hæres. 7, could not persuade himself it was true.

RHETORIC, Rhetorica, formed from ῥητορικη, of ῥεω, *I speak*, whence ῥητωρ, *speaker*, *orator*, *&c.* the art of speaking copiously on any subject, with all the advantages of beauty and force.

Rhetoric is generally considered as the art of persuasion. It attempts to produce conviction concerning some particular object, that it may influence the will to a corresponding determination. It seeks either to arouse the mind to action, or to dissuade it from acting upon the resolutions already taken, or such as are in contemplation. Its immediate employment is not to search after truth, but to render acknowledged or supposed truths influential. It leaves to logic the province of cool investigation, and of drawing legitimate conclusions from admitted premises, without any regard to motives. The rhetorician is solicitous to effect some particular purpose, and calls in the art of reason merely as an auxiliary. He attempts to influence the will by reasoning with the affections; knowing that if they be gained over to the party espoused, the will is ready to follow. He, therefore, artfully conceals, or slightly passes over, every circumstance which is not favourable to his views, and brings forwards and largely expatiates upon those which are. He suggests motives of pleasure, utility, safety, honour, pity, &c. as the subject admits. He not only pre-supposes the object in view of the first importance, but he employs every method to implant this conviction in the minds of those whom he endeavours to persuade. These attempts become most successful by a close imitation of that train of ideas, and those modes of expression, which any particular passion or affection is prone to suggest. If the design be to excite *anger* and *resentment*, rhetoric imitates the language of anger. It places the supposed offence in the strongest point of view, and describes it in the most vivid colours. It assiduously collects and expatiates upon every circumstance which contributes to the aggravation of the crime. It is indignant against that spiritless tranquillity which can patiently endure such insults, and attributes reluctance to revenge to mean and cowardly motives. If its object be to excite *horror*, it assembles together every circumstance which has a tendency to alarm with a sense of danger. It stigmatises courage with the epithet of rashness, and flight is dignified with the title of prudence, &c. If *compassion* be the object, it expatiates upon the wretched state of the sufferer; his fears, his apprehensions, his penitence. It palliates his faults, extols his good qualities, and thus collects, in one point of view, all his claims on commiseration. The species of argument, which persons under the influence of passions and strong affections perpetually adopt, is rendered more efficacious by appropriate language. The rhetorician, therefore, studies and imitates the particular language of each passion, either in its energy, vivacity, or diffuseness. Hence he liberally employs all those tropes and figures of speech which nature suggests, and art has classified.

Oratory adds to rhetorical composition the advantages of *elocution*. It adapts the manner of delivery to the nature of the subject and the appropriate language. It takes the characteristic signs of each emotion for its model, as far as it dares to imitate, without the imputation of mimickry; it enters into the attitudes, gestures, tones of voice, accents, emphasis, expressions of countenance, inspired by the particular emotion, in such a manner, that not an idea is suffered to lose its proper effect, by any deficiency in kind or degree of energy communicated to it; and thus it enjoys every advantage to be derived from the power of sympathy.

Eloquence, according to the modern ideas of it, appears to be the medium between the impetuosity which oratory admits, and which was highly characteristic of ancient oratory, and the studied artifice of the professed rhetorician. The term is sometimes applied to *composition*, and sometimes to *delivery*. When applied to both, it comprehends a certain degree of elegance, both of diction and of manner. The want of that energy which approaches to violence, is compensated by pertinency of language, fluency of utterance, and guarded chastity of address. In a word, its excellency consists in a pleasing adaptation of language to the subject, and of manner to both. It refuses too close an imitation of the turbid emotions, but it delights in animated description. It seems rather partial to the pathetic; the elegance and graces which it loves, harmonize most easily and successfully with the softest and finest feelings of our nature. (Cogan on the Passions.) RHEU, La, in *Geography*, a town of France, in the department of the Ille and Vilaine; five miles W.S.W. of Rennes.

RHEUM, in *Botany*, a name derived, as Linnæus supposes, from ῥεω, *to flow*, on account of its active medicinal properties. The Ῥηον, or Ῥα, of Dioscorides is probably of this genus, and the origin of the name.—Linn. Gen. 201. Schreb. 271. Willd. Sp. Pl. v. 2. 488. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 2. 430. Juss. 82. Gærtn. t. 119. Lamarck Dict. v. 6. 192. Illustr. t. 324. (Rhabarbarum; Tournef. t. 18.) Rhubarb.—Class and order, *Enneandria Monogynia*. Nat. Ord. *Holeraceæ*, Linn. *Polygoneæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, narrowed at the base, withering, but permanent, cloven into six obtuse segments, alternately smaller. *Cor.* none, except the three inner segments of the calyx be considered such, as in *Rumex*. *Stam.* Filaments nine, capillary, equal in length with the calyx, and inserted into it; anthers twin, oblong, obtuse. *Pist.* Germen superior, short, triangular; styles scarcely any; stigmas three, reflexed, feathery. *Peric.* none. *Seed* solitary, large, triangular, acute, with membranaceous margins.

Eff. Ch. Calyx six-cleft, permanent. Seed one, triangular.

1. R. *Rhaponticum*. Rhapontic Rhubarb. Linn. Sp. Pl. 531. Alpin. Rhapont. 1. t. 1.—"Leaves obtuse, smooth;

ſmooth ; veins ſomewhat hairy beneath ; the ſinus dilated at the baſe : ſtalks furrowed on the upper ſide, rounded at the edge."—Native of Aſia, and cultivated, like all the other ſpecies (except *Leucorrhizum*), at Kew, where they moſtly flower in May and June.—*Root* large and thick, much divided, reddiſh-brown on the outſide, yellow within. *Stems* from two to three feet high, jointed, purple. *Leaves* not expanded at firſt, but folded, ſmooth, roundiſh heart-ſhaped, on thick, reddiſh, channelled ſtalks, which have an acid flavour, and are uſed for making tarts. *Flowers* white, forming a thick, obtuſe, denſe tuft, which becomes a panicle of large, triangular, brown *ſeeds*.

2. R. *undulatum*. Waved-leaved or Chineſe Rhubarb. Linn. Sp. Pl. 531. Amœn. Acad. v. 3. 230. t. 4.—"Leaves rather hairy, undulated ; the ſinus dilated at the baſe : ſtalks flat above, ſharp at the edges."—Native of China and Siberia.—*Root* compoſed of numerous thick fibres, running further into the ground, and of a deeper yellow than the foregoing. *Stem* upright, three or four feet in height, of a pale browniſh colour. *Leaves* ſomewhat tapering, much waved at their edges, ſtrongly veined beneath. *Flowers* white, in looſe panicles or bunches. *Seeds* of a ruſty brown.

3. R. *palmatum*. Officinal or Turkey Rhubarb. Linn. Sp. Pl. 531. Mill. Illuſtr. t. 30. Woodv. Med. Bot. 127. t. 46.—"Leaves palmate, pointed, roughiſh ; the ſinus dilated at the baſe : ſtalks obſoletely furrowed above, rounded at the edge."—Native of China and Tartary.—*Root* perennial, thick, oval, ſending forth numerous tapering branches, externally brown, internally yellow. *Stem* erect, ſix or eight feet high, round, hollow, jointed, ſheathed, ſlightly furrowed, branched towards the top. *Radical-leaves* numerous, large, rough, roundiſh, deeply lobed ; *ſtem-leaves* one at each joint, from a membranous ſheath, ſmaller upwards. *Flowers* of a greeniſh-white colour, ſurrounding the branches in numerous cluſters, forming a kind of ſpike.

The roots of this and the laſt ſpecies conſtitute the drugs which in our ſhops are known by the names of Chineſe and Turkey Rhubarb, although other ſpecies of *Rheum*, eſpecially *compactum*, poſſeſs like medicinal properties, and their roots are of courſe ſometimes ſubſtituted for the true ones. Profeſſor Martyn and Dr. Woodville have taken great pains to illuſtrate this genus, ſo juſtly celebrated for its purgative qualities. Dr. Pulteney remarks, that if *R. undulatum* and *R. palmatum* are planted near each other, they produce a hybrid variety, more excellent in kind than the parent plants.

4. R. *compactum*. Thick-leaved Rhubarb. Linn. Sp. Pl. 531. Mill. Ic. v. 2. 145. t. 218.—Leaves ſomewhat lobed, very obtuſe, lucid, ſharply toothed, quite ſmooth.—Native of Tartary.—*Roots* large, much divided, yellow within. *Stems* five or ſix feet high, green, branched at the upper part. *Leaves* long, broad at the baſe, coriaceous and compact, rather waved, and having a ſharp acid flavour. *Flowers* white, forming an erect panicle or ſpike. This is frequently ſubſtituted for the real rhubarb.

5. R. *tartaricum*. Tartarian Rhubarb. Linn. Suppl. 229. Willd. n. 5.—Leaves ovate, heart-ſhaped, undivided, flat, ſmooth, on roundiſh, angulated ſtalks. Panicle furrowed.—Native of Leſſer Tartary. We know of neither ſpecimen nor figure of this ſpecies. Linnæus deſcribed it from the Upſal garden as having large *leaves*, the radical ones procumbent, with dilated veins, on red ſtalks, which are convex beneath. *Infloreſcence* ſcarcely higher than the leaves.

6. R. *Ribes*. Warted-leaved Rhubarb. Linn. Sp. Pl. 532. Desfont. in Ann. du Muſ. v. 2. 261. t. 49. (Lapathum orientale, aſpero et verrucoſo folio, Ribes Arabibus dictum ; Dill. Elth. v. 1. 191. t. 158. f. 192.)—Leaves very obtuſe, verrucoſe, with ſpinous veins beneath ; ſtalks flat above, rounded at the margin.—Native of the Levant ; on mount Libanus, and other mountainous parts of Syria.—*Root* thick and fleſhy. *Stems* two feet high, hairy, green, tinged with purple towards the bottom. *Leaves* large, curled at the edges, veined, of a purpliſh-green colour, paler beneath, ſtudded with warts. Linnæus, who had never ſeen the flower, referred this plant to *Rheum* from its habit.

7. R. *hybridum*. Baſtard Rhubarb. Willd. n. 7. Murray in Comment. Gott. 1779, 7. t. 1.—Leaves ſmooth above, rather hairy beneath, ſlightly lobed, acute ; the ſinus narrowed at the baſe ; ſtalks obſcurely furrowed above, rounded at the margin.—Native of the north of Aſia.—Very ſimilar in habit and appearance to *R. palmatum*, and we are much diſpoſed to conſider it, with profeſſor Murray, as a hybrid plant produced between that and ſome other ſpecies. The *leaves* of this are not ſo much nor ſo deeply cut as thoſe of *palmatum*.

8. R. *leucorrhizum*. White-rooted Rhubarb. Willd. n. 8. Pallas Nov. Act. Petrop. 1792, 381.—Leaves tranſverſely oval, depreſſed. Panicle divaricated when in ſeed. Two ſegments of the calyx many times larger than the reſt.—Native of deſart places, on the mountains of Siberia.—Adopted by Willdenow, on the authority of Pallas, who deſcribes it thus. "*Radical-leaves* uſually three, procumbent, four or five inches wide, three-nerved, much veined, ſmooth, coriaceous, lengthened out at the baſe ; rough at the edges, with very minute, cartilaginous, acute crowded teeth. *Stalks* compreſſed, ſmooth, ſolid, ſucculent. *Flowering-ſtem* a ſpan high, furrowed, panicled."

Rheum, in *Gardening*, contains plants of the herbaceous, perennial, luxuriant kind, of which the ſpecies chiefly cultivated are ; the rhapontic or common rhubarb (R. rhaponticum) ; the palmated-leaved (R. palmatum) ; the compact thick-leaved rhubarb (R. compactum) ; the waved-leaved Chineſe rhubarb (R. undulatum) ; the warted-leaved Perſian rhubarb (R. ribes) ; and the Tartarian or heart-leaved rhubarb (R. tartaricum.)

It is ſtated, on the authority of ſeveral cultivators of the firſt ſpecies of this plant, by the editor of Miller's Dictionary, that by proper attention in the growth and preparation of the root, it may be obtained here nearly in equal goodneſs to the foreign.

Method of Culture.—Theſe plants are all increaſed by ſeeds, which ſhould be ſown in autumn ſoon after they are ripe, where the plants are deſigned to remain, as their roots being large and fleſhy when they are removed, they do not recover it ſoon ; nor do the roots of ſuch removed plants ever grow ſo large and fair as thoſe which remain where they were ſown. When the plants appear in the ſpring the ground ſhould be well hoed over, to cut up the weeds ; and where they are too cloſe, ſome ſhould be cut up, leaving them at the firſt hoeing ſix or eight inches aſunder ; but at the ſecond, they may be ſeparated to a foot and a half diſtance, and more. When any weeds appear, the ground ſhould be ſcuffled over with a Dutch hoe in dry weather ; but after the plants cover the ground with their broad leaves, they keep down the weeds without any further trouble. The ground ſhould be cleaned in autumn when the leaves decay, and in the ſpring, before the plants begin to put up their new leaves, be dug well between them. In the ſecond year, many of the ſtrongeſt plants will produce flowers and ſeeds, and in the third year moſt of them. It is adviſed, that the ſeeds be carefully gathered when ripe, and not permitted to fcatter, left they grow and injure the old plants.

The roots continue many years without decaying, and it is faid that the old roots of the true rhubarb are much preferable to the young ones. The roots may be generally taken up after four years, but if they remain longer, it is fo much the better.

Thefe plants delight in a rich foil, which is not too dry nor over moift: and where there is a depth in fuch land for their roots to run down, they attain a great fize, both in the leaves and roots.

Some cultivators think that the fowing is beft performed in the later fpring months; but in this way, as the feeds are flow in vegetating, there is much time loft. And a hot-bed has been fometimes employed, though it is not much advifed.

The rhubarb plants may be alfo increafed from offsets, feparating fome of the eyes or buds which fhoot out on the upper parts of the root, together with a fmall part of the root itfelf, having fome of the fibres to it. Thefe offsets may be taken from roots of three or four years old, without any injury to the plant. By this method a year is faved, and the plants are not in fuch danger of being devoured by vermin as thefe from feed, nor fo uncertain in growing; they are not fo tender, and only require keeping clear of weeds. There is no difference in the fize of the roots thus raifed, from thofe which grow from feeds. This method was practifed by Mr. Hays, and in Mr. Hayward's practice feveral offsets were flipped from the heads of large plants in the fpring, and fet with a dibble about a foot apart. Four years after, he took up the roots, and found them very large, and of excellent quality. On further experience, when he took up his roots, either in fpring or autumn, he divided the head into many parts; thefe he planted directly, at two feet diftance, if intended for future removal; but if to remain for a crop, at four feet and a half.

And in the culture of this root for medicinal ufes, the nature of the afpect is faid not to be very material, provided it be not fhaded too much on the fouth or weft. The indifpenfable points are the depth and good quality of the foil, which fhould be light, loamy, and rich, but not too much fo, left the roots be too fibrous: it can fcarcely be too dry, for more evil is to be expected from a fuperabundancy of moifture than from any actual want of it. If, with thefe advantages, the plantation can be placed on a gentle declivity, fuch a fituation may be faid to be the moft defirable. Where a plantation does not poffefs the natural advantage of being on a declivity, narrower beds and deepened trenches are among the artificial means that fhould be adopted; but moft fituations will require fome care to prevent the ill effects of water remaining on the crowns of the plants: therefore, when the feed-ftalks are cut off, which ought always to be done immediately upon the withering of the radical leaves, they fhould be covered with mould, in form of a hillock. This procefs will anfwer two good purpofes; that of throwing off the rain, and keeping open the trenches by taking the earth from them. And it is obferved, that the injuries to which the young plants are moft liable, are from flugs and other vermin, from inattention to the feafon and manner of planting, and from too great an expofure to froft. Little damage is to be feared from heat; and, in general, they are hardy and eafy of cultivation when arrived beyond a certain term. It is advifed to take great care of the nurfery bed, as the pains beftowed by conftant waterings, and protecting the young plants from the ravages of infects, will amply repay the planter. Roots that thrive well here, will in three years arrive at an equal fize with others, that have not fucceeded fo well at the end of five. When a plantation is to be formed, or a vacancy filled up, felect the fineft and moft thrifty plants. No plant will come to any thing when it has loft its principal bud.

It is alfo obferved, that there is a difference of opinion in refpect to the age at which the roots ought to be taken up for ufe; but it is probably beft done from four to eight years. They are the beft when taken up in autumn, in a dry time, and fhould be immediately dried and prepared by cutting into pieces and cleaning, hanging them on proper ftrings in a dry airy place.

And fome plants of each of the forts may alfo be introduced in the dry borders and clumps, for the ornamental effect of the leaves and flowers.

RHEUM, in *Medicine*, ῥευμα, *defluction*, a term which was in common ufe in the vocabulary of the humoral pathologifts, to denote the fluid difcharged from a part, as of mucus in coryza and catarrh, and alfo a fuppofed accumulation or congeftion of fluid in a part. In their doctrine, every inflammation and tumour was afcribed to a defluction of fome humour in the part affected; but modern obfervation has taught us, that the accumulation of fluid, in thefe cafes, is generally the effect, and not the caufe, of the difeafe; being the confequence of inflammatory action of the veffels, which produces an increafed difcharge and an altered condition of their fecreted fluids. Although the term and the doctrine are both exploded, they have left a popular appellation attached to a difeafe, which is univerfally called *rheumatifm*.

RHEUMATISM, from the preceding word, a painful difeafe ufually affecting the joints, and fometimes the mufcles. The appellation feems to have been firft limited to this diforder by a celebrated French writer, Baillou, or, as he calls himfelf in Latin, Ballonius; and has fince been adopted both by the erudite and the vulgar.

Rheumatifm affumes two or three forms, remarkably different from each other, independently of the varieties which difference of feat occafions; a difference, indeed, which is rather nominal than real. Of the latter diftinctions, we have *lumbago*, when the difeafe is feated in the loins (*lumbi*); *ifchias*, or *fciatica*, when it occurs in the hip; and *pleurodyne*, when it attacks the fides, which are lined with the membrane called *pleura*, &c. The more remarkable fpecies of the difeafe, however, to which we have alluded, are the *acute* and *chronic* forms which it exhibits. There is alfo a third form, partaking more of the acute than of the chronic fpecies, which has been called, with fome impropriety, *rheumatic gout*, or *arthritis rheumatica*. It will be neceffary to fpeak of the acute and chronic rheumatifm, as well as of the rheumatic gout, feparately; fince the treatment, which they refpectively require, is confiderably different.

RHEUMATISM, *Acute*, otherwife called *rheumatic fever*, begins, like moft other febrile difeafes, with fits of chillinefs, which are fucceeded by increafed heat, frequent pulfe, thirft, lofs of appetite, and proftration of ftrength. Not unfrequently, however, the peculiar fymptoms appear before any febrile fymptom is obferved; namely, pain and inflammation in the joints. The pain fometimes affects the joints alone, but often it affects alfo the mufcular parts, fhooting along the courfe of the mufcles from one joint to another; and it is always increafed by the action of the mufcles, that is, by any attempt to move the joints that are difeafed. Its ufual feat is in the larger joints, fuch as the hips, knees, fhoulders, and elbows: the ankles and wrifts are alfo frequently attacked; but the fmaller joints, fuch as thofe of the toes and fingers, fuffer confiderably lefs. Two, three, or more of thefe joints are commonly affected at the fame time:

time; but the pain is conftantly fhifting its place, leaving fome joint and going to another, and frequently returning again to each of them feveral times during the courfe of the difeafe; and in this manner the difeafe is often protracted for a confiderable length of time. Soon after, and fometimes at the fame moment with the commencement of the pain, the joint feized becomes fwelled and fomewhat red; and this fwelling is extremely painful to the touch. The pain is fometimes relieved by the occurrence of fwelling, but not always; neither is the joint thus rendered more fecure from a return of the attack. The patient, thus unable to move the joints affected, which are irritated and acutely pained by external contact, fometimes even by the weight of the bed-clothes, and in a ftate of fevere internal pain, unable to find any pofition of eafe, lies fleeplefs and reftlefs for feveral days and nights together. The fever accompanying the difeafe is moft confiderable during the night, at which time the pains alfo are moft violent. The pulfe is commonly from ninety to a hundred in a minute, and occafionally more frequent; often full, and fometimes hard and fharp, but moft frequently foft. The heat of the fkin is confiderable, and the difeafe is commonly attended with fweating, even from an early period, which is often profufe and conftant, but never either relieves the pains permanently, or proves a crifis to the fever. The urine, in acute rheumatifm, is remarkably high-coloured from the beginning, and afterwards depofits moft copioufly a brownifh-red fediment, like brick-duft. This fediment, however, is probably the refult rather of the profufe fweating, than of any peculiarity belonging to the difeafe; fince it is commonly feen after a dofe of fudorific medicine, or any other variety of perfpiration. Like the fweating, it does not occafion or betoken any favourable change in the fever. When blood is drawn in this difeafe, it always exhibits, and generally in a high degree, the buffy coat, as it is called, or a coriaceous covering of coagulable lymph, on its furface.

With the fymptoms above detailed, the rheumatic fever often continues for feveral weeks: it feldom, however, proves fatal, and perhaps never, while the joints alone are the feat of the difeafe; the fever, indeed, ufually becomes lefs violent after two or three weeks, and the pains lefs fevere, and lefs difpofed to change their place. But occafionally the inflammation of the joints has difappeared, and fome vital organ, as the brain, lungs, or ftomach, has been feized with inflammation, by which the patient has been carried off; or thefe organs have become fimultaneoufly affected, and the fame fatal event has enfued. We have had occafion to witnefs two inftances of this kind, out of feveral hundreds of cafes, in which a tranfition of the difeafe from the joints to the lungs took place, or, at leaft, in which, on the fpeedy ceffation of rheumatifm in the joints, a violent inflammation of the lungs fupervened, and terminated fatally. We have alfo feen fuch a metaftafis to the lungs, which was removed by vigorous treatment. The venerable Dr. Haygarth, however, has given a more unfavourable ftatement of this matter from his experience; for "out of 170 cafes," (fpeaking of acute rheumatifm,) he fays, "I have found twelve which had a fatal termination, either by a tranflation of the inflammation to the brain, lungs, kidnies, ftomach, or fome other vital part, or as being found in combination with other difeafes." (See Clinical Hift. of Acute Rheumatifm, p. 61.) Dr. Cullen has not mentioned any fuch refult of the difeafe. From the obfervations of our contemporaries, it has been found that the heart is peculiarly liable to be affected by a metaftafis of rheumatic inflammation, or to be attacked with a flow difeafe, by which its bulk becomes increafed, and its functions difturbed, after the ceffation of acute rheumatifm. This fact was firft mentioned by Dr. Baillie, on the authority of the late Dr. Pitcairn, and has fince been more fully eftablifhed by the records of feveral cafes. See efpecially a paper by Mr. ferjeant-furgeon Dundas, in the firft volume of the Medico-Chirurgical Tranfactions; alfo Dr. Baillie's Morbid Anatomy.

It has been remarked by Dr. Cullen, as indicative of the peculiar nature of rheumatic inflammation, that "the acute rheumatifm, though it has fo much of the nature of the other phlegmafiæ, differs from all thofe hitherto mentioned in this, that *it is not apt to terminate in fuppuration.* This almoft never happens in rheumatifm; but the difeafe fometimes produces effufions of a *tranfparent gelatinous fluid* into the fheaths of the tendons. If we may be allowed to fuppofe that fuch effufions are frequent, it muft alfo happen that the effufed fluid is commonly re-abforbed; for it has feldom happened, and never indeed to my obfervation, that confiderable or permanent tumours have been produced, or fuch as required to be opened, and to have the contained fluid evacuated. Such tumours, however, have occurred to others, and the opening made in them has produced ulcers difficult to heal." (See Cullen, Firft Lines, par. 448.) The non-occurrence of fuppuration in thefe violent rheumatic inflammations is of itfelf a ftriking characteriftic of the difeafe; and the circumftance, that it is not productive, on the other hand, of what are called *chalk-ftones*, or of that cretaceous-like fecretion which is the refult of the inflammation of gout, diftinguifhes it from the latter malady. In addition to this circumftance, however, there are other points of diftinction between the *gouty* and *rheumatic* inflammation; namely, that the latter ufually attacks the large joints; that it is not preceded by fymptoms of indigeftion; that it does not recur in regular paroxyfms; and that it attacks younger people, and thofe not liable to gout from their modes of life; and, as we fhall fee immediately, is ufually the effect of a fpecific caufe, cold.

Caufes of Acute Rheumatifm.—The circumftances which conftitute a predifpofition to the attacks of acute rheumatifm are various. Perfons of an irritable, plethoric, or fanguineous habit, are moft liable to be affected, when expofed to the action of the exciting caufes; and a certain period of life, in which there is a confiderable vigour in the fanguiferous fyftem, alfo predifpofes to it. It affects, indeed, perfons of all ages, from five to above fixty years; but is much the moft frequent between the time of puberty and the thirtieth year. Dr. Haygarth confiders it as moft common between fifteen and twenty. Some difference has been fuppofed to exift with refpect to *fex;* fince it is certain that males are much more fubject to the difeafe, in this country, than females; Dr. Haygarth fays, in the proportion of nearly four to three. But it is probable, as the fame writer fuggefts, that this arifes from the more conftant expofure of men to cold and rain, by the nature of their occupations, than women; whence, he was informed, that, in Holland, the rheumatifm is feldom found in women, though the air is very humid, becaufe they are more domefticated than in this country, and their drefs is warmer. Preceding attacks of the difeafe feem to afford a ftrong predifpofition to future recurrences of it.

When thefe predifpofitions exift, the acute rheumatifm is readily excited by the fudden application of cold or damp, when the body has been already much heated, and is perfpiring after fatigue; or when one part of the body is expofed to cold, while the other parts are kept warm; or, laftly, by any long continued application of cold and moifture, under any circumftances, as by wearing wet or damp

 clothes.

clothes. Whence the disease is almost exclusively observed in cold and changeable climates; and is most frequent in the most variable seasons, as in the spring and autumn, very seldom occurring during the steady heat of summer.

Cure of Acute Rheumatism.—With respect to the treatment, which is most successful in the removal of this distressing and painful malady, considerable difference of opinion, and some fluctuations of opinion, have taken place among professional men. The acute pain, the great heat, the quickness and fulness of the pulse, and the buffy or inflammatory appearance of the blood, when drawn, have led the majority to look upon it as a highly inflammatory disease, and to be cured almost exclusively (like the other organic inflammations) by copious *blood-letting*. Boerhaave maintained this doctrine; and Cullen followed him to the full extent. "The blood ought to be drawn in *large quantity*," says the latter, "and the bleeding is to be *repeated* in proportion to the frequency, fulness, and hardness of the pulse, and to the violence of the pain. For the most part, *large and repeated* bleedings, during the first days of the disease, seem to be necessary, and accordingly have been very much employed; but to this some bounds are to be set: for very profuse bleedings occasion a slow recovery, and, if not absolutely effectual, are ready to produce a chronic rheumatism." (First Lines, parag. 463. See Boerhaave, app. 1493.) The Cullenian doctrine is, we believe, even now taught in the school of Edinburgh, with scarcely any of the cautionary bounds mentioned by that sagacious practitioner. Sir John Pringle trusted much to the same practice. Sydenham began his career by ordering four bleedings for the cure of rheumatism; but he appears to have gradually declined in his attachment to that practice, and says, that he found it better to purge after the second bleeding. And again, in the last piece which he ever wrote, he says, "If we obstinately persist in these evacuations, till the symptoms entirely go off, the disease will often terminate fatally." (Sched. Monitor.) He also says, in his Processus Integri, which he composed for the use of his son, that in young persons, who live temperately, "the rheumatism may be as successfully cured by a very cooling and moderately nourishing diet, as by repeated bleedings, which they cannot so well bear." Van Swieten, who has traced out this progress of Sydenham's experience, admits that he has cured many cases of acute rheumatism without bleeding, if they were mild in the beginning.

Now this has been the progress of the general experience in our own times; and at present, few English physicians deem blood-letting the leading remedy for acute rheumatism. On the contrary, the most experienced have fully decided, that, in the great majority of cases, evacuation is entirely unnecessary; and that, if it is frequently repeated, it does a material injury, by sinking the patient into a long and tedious chronic disease, as Dr. Cullen stated, from which there is sometimes no recovery; and always occasions a lingering convalescence. Perhaps the only cases in which it is requisite are in persons of highly vigorous and inflammatory habits, in whom a single bleeding may diminish that diathesis; and in those cases in which metastasis threatens, or actually takes place. Where this translation has indeed already occurred to any vital organ, as the lungs or brain, then the most vigorous venesection must be resorted to, as for the most dangerous forms of pleurisy or phrenitis.

But, we repeat it, experience has legitimately proved, that blood-letting may be superseded altogether, in a great majority of cases of acute rheumatism, by other remedies. These other remedies, to which different practitioners have resorted, have been chiefly *purgatives*, *sudorifics*, *opiates*, and the Peruvian *bark*, of each of which it will be necessary to take some notice; for they are all useful under certain conditions of the patient and the disease, and constitute the principal means of cure.

Purgatives, as they contribute, if properly selected, to reduce every species of febrile excitement, though they are alone incapable of effectually relieving this disease, are yet essentially beneficial as a part of the plan of cure. The saline purgatives, such as the sulphate of magnésia, are the best adapted to relieve the bowels and the system at large; or they may be assisted by moderate doses of calomel, which perhaps more effectually empties the upper bowels. They become also more particularly necessary, when the narcotic medicines, to be mentioned presently, are administered, with a view to obviate the constipation which the latter produce. But no practitioner would confide in cathartics alone for the cure of acute rheumatism.

With respect to *sudorifics*, there is a more general tendency to trust the cure to them; partly because the pains are often said to be easier, while perspiration is present; and partly with the view of assisting the apparent efforts of the constitution. It may be remarked, however, that although the most profuse sweats very frequently break out spontaneously, they seldom afford any essential relief; and they will continue day after day, without any apparent influence upon the disease. Accordingly, much direct benefit could not in reality be expected to arise from augmenting a discharge, already very profuse, and of considerable duration; and, in truth, we believe mere sweating is productive of no benefit. But the medicines given as sudorifics, especially antimonials and Dover's powder, operate beneficially perhaps by their other qualities. Thus the antimonials, and the ipecacuanha, and salt of this powder, are kindly and gentle laxatives, and thus produce an antiphlogistic effect as evacuants; but the principal operation of the powder of Dr. Dover is probably the result of the opium which it contains.

For *opiates* alone, that is, uncombined with antimony or ipecacuanha, have been relied upon by some practitioners, and with the most marked success. As opium, and other substances, possessing a similar narcotic power, have been known from ancient times to be highly stimulant, that is, to cause an increased activity and vigour in the circulation and nervous system, and therefore to be highly injurious in active inflammations; so all those physicians, who advocated venesection, shunned the use of opiates religiously: and even those, who found by experience that blood-letting was not required, questioned nevertheless the impunity with which opiates might be administered. Experience, however, has now fully determined this point also; that opium may be administered largely, not only with safety, but with most essential benefit, in the most severe cases of acute rheumatism. As far as our own observation has gone, indeed, (and we have had occasion to treat some hundreds of persons affected with this malady,) the combination of repeated doses of opium, with a daily saline laxative, with copious thin diluent drinks, and a light diet, in the beginning of the disease, constitutes the most successful management of the disease; a practice which, it is but justice to say, was introduced into St. George's hospital, many years ago, by the present senior physician, Dr. George Pearson. From half a grain to a grain, or more, of solid opium may be given three times a day, in the combination just mentioned, without affecting the head or the stomach, with great, speedy, and often permanent relief to the disease, and without leaving the tendency to a slow convalescence, or a chronic malady, like the violent depletory system.

In

In favour of the treatment of this apparently acute inflammation by the ftill more oppofite means of a powerful tonic, the *cinchona*, or *Peruvian bark*, the recorded teftimony is ftill more confiderable. Dr. Cullen affirmed of the bark, that he had "feldom found it ufeful, and in fome cafes hurtful," when employed before the phlogiftic diathefis was abated, and fomething like remiffions occurred in the fever. Other practitioners, however, have confidered thefe previous changes unneceffary, except in a very partial degree, and contend, that the early ufe of the bark is the moft efficacious mode of curing acute rheumatifm. Dr. Haygarth is one of the moft ftrenuous advocates for this practice; indeed, a conviction of its advantages is the avowed motive for the publication of his "Clinical Hiftory" of the difeafe, to which we have already referred. He was led to the adoption of the remedy early, on the recommendation of the celebrated Dr. Fothergill, who received it from fir Edward Hulfe. Dr. Haygarth has recorded eighty-four cafes in which the cinchona was adminiftered, in general, very early in the difeafe, after a moderate evacuation of the ftomach and bowels, principally by means of antimonial medicines. On fome occafions, however, Dr. Haygarth alfo preceded the ufe of this remedy by a bleeding, where the fymptoms were very violent.

On the whole, the inference which we are difpofed to draw from thefe authorities, aided by perfonal obfervation, is, that the moft fuccefsful practice confifts in a free purgative evacuation, and an occafional bleeding in particular habits, in the very onfet of the difeafe, followed immediately by the free ufe of opiates, with copious drinks and faline laxatives, and this fucceeded, without delay, when the pains and tumours have fomewhat remitted, by a refort to the decoction of cinchona, or fome gentle tonic.

All external applications to the parts which are fwelled and painful, in acute rheumatifm, are of little or no fervice. The warm bath and fomentations, efpecially in the beginning of the difeafe, rather aggravate than relieve the pains. Bliftering, or the minor degree of fuperficial inflammation produced by rubefacients, if they diminifh the pain in one part, generally only occafion it to fhift to another, and do little towards the cure of the general affection. The fame obfervation is applicable to refrigerant remedies, fuch as to wafhing with cold water or other lotions the tumid joints; the difeafe but changes its ftation, without any tendency to ceafe altogether; and the change of fituation, though it is commonly from joint to joint, may neverthelefs occafionally take place from the joints to a more important organ.

Rheumatism, *Chronic.* In many inftances, this form of rheumatifm is the direct confequence of an attack of the acute form of the difeafe. The febrile fymptoms, the fwelling, and particularly the rednefs of the joints, have difappeared, and the general functions have refumed their healthy condition; but ftill certain joints continue to be affected with pains and ftiffnefs, which are particularly felt on motion, and are often accompanied by a fpontaneous coldnefs, and a torpor, fometimes almoft amounting to paralytic. Thefe affections are much influenced by the changes in the temperature and humidity of the atmofphere, and are diftinctly aggravated by external cold, and relieved by external warmth. The parts affected are not eafily made to perfpire, and when the other parts of the body are brought into a ftate of free and warm perfpiration, that on the pained joints is only cold and clammy. The pains are alfo, like thofe of acute rheumatifm, moft fevere in the night.

This chronic affection of the joints, however, is very often altogether independent of any previous inflammation and fwelling, and occurs in many perfons who have never been fubject to an attack of acute rheumatifm. It occurs, indeed, very frequently in perfons fomewhat advanced in life, and beyond the period when the acute form of the malady is ufually feen. In thefe cafes it is commonly afcribed to the action of cold; very often to partial expofures of the particular parts of the body in which it takes its feat; and it is apt to be produced again and again in thofe parts which have once fuffered from expofure of other parts of the body to cold. Thus, getting the feet wet will induce an attack of lumbago, fciatica, or a crick in the neck, according to the predifpofition induced in thefe refpective regions by former attacks. Many cafes of chronic rheumatifm are afcribed, however, to violent ftrains of the mufcles of particular parts, occurring on fudden and fomewhat violent exertions, and even to fatigue from long continued exertions of particular mufcles.

As the exact nature of the affection called chronic rheumatifm is not very clearly underftood, fo the method of cure, which is ufually purfued, is fomewhat empirical; *i. e.* the mere refult of the obfervation of the effects of different medicines which have been tried. Dr. Cullen, indeed, attempted to explain the nature of the difeafe, by faying, that it confifted in "an atony both of the blood-veffels and of the mufcular fibres of the part affected, together with a degree of rigidity and contraction in the latter, fuch as frequently attend them in a ftate of atony;" and therefore concluded, that fuch remedies were required, as were fuited "to reftore the activity and vigour of the vital principle in the part." The explanation of Dr. Bardfley, however, though not very different, is perhaps more confonant to the general opinion upon this fubject. He confiders the principle of cure as fimple and uniform; namely, that "it confifts in removing paffive inflammation, and reftoring the debilitated veffels and mufcular fibres to their due tone and action." (See Dr. Bardfley's Medical Reports, p. 4.) The remedies by which thefe objects are attained, may be included under two heads, internal and external.

The *internal* remedies which have been recommended for the cure of chronic rheumatifm, though very numerous, have, on the whole, been found to poffefs a very uncertain power over the fymptoms of that difeafe; and many which have been highly extolled, have been given up in total difappointment. Neverthelefs, in many inftances, thefe remedies are effentially beneficial, fometimes curing the difeafe alone, and generally aiding the operation of external applications. They may be defcribed under the denomination of fudorifics and ftimulants, or ftimulant-diaphoretics, to which may be added mercurials, and fome individual articles of peculiar operation.

Thefe fudorifics appear to poffefs very little remedial power over the chronic rheumatifm, and the lefs in proportion as the difeafe partakes lefs of the fwelling and inflammation of the acute fpecies, or as it is of longer ftanding. In the majority of cafes they are even worfe than ufelefs. Dr. Bardfley fays, "in fhort, I can fpeak decidedly of the injurious effects of fudorifics, when pufhed to any great extent, in every inftance of fevere local affection of the joints; and alfo in moft other cafes, where the difeafe has been long continued, and the patient's conftitution much debilitated. In chronic lumbago and fciatica, I have never experienced any lafting benefit to refult from this mode of practice." Dr. Bardfley, indeed, fpeaks very lightly of the effects of all the internal remedies, not only of this, but of the ftimulant

lant clafs. He admits that fmall dofes of antimonial powder, combined with calomel and opium, are certainly ufeful in allaying pain and irritation; but he believes that their efficacy confifts rather in palliating fymptoms, than in curing the difeafe, when it is confiderable in degree and obftinate in kind. "The fame obfervation," he fays, "will nearly apply to the ufe of ftimulant remedies, fuch as refin of guaiacum, the clafs of terebinthinates, and of effential oils. In the moft aggravated inftances of general chronic rheumatifm, where great torpor and debility prevailed, guaiacum, in fuch large dofes as the ftomach and bowels would bear, was found to be a powerful auxiliary; and certainly the moft generally efficacious of all the internal remedies that were employed. But I have feen no inftance of its complete fuccefs, when unaided by topical applications, in any fpecies of the difeafe where much local injury of the joints had taken place. It acted moft beneficially when exhibited in fubftance, well triturated with mucilage; to which was occafionally added gum kino, or tincture of opium, to prevent its effects on the bowels. In many obftinate cafes, the ammoniated tincture of guaiacum, incorporated with mucilage, and joined to a ftrong decoction of bark, proved of great fervice, where the conftitution was broken down by the violence and length of the difeafe. There were but few protracted cafes in which the Peruvian bark was not prefcribed with advantage as a tonic, efpecially at the clofe of the difeafe. It was, however, never adminiftered with any other defign than as an auxiliary." (Loc. cit. p. 16.) We have quoted this paragraph, as containing the refult of the deductions from a large number of cafes, treated in a public hofpital, by a careful and intelligent obferver; and, therefore, as affording a probable approximation to the general fact of the operation of thefe medicines. The fame obfervations, we believe, are applicable to fome of the other remedies, of a ftimulant and diaphoretic quality, which are often reforted to; fuch as the preparations of ammonia, infufion of horfe-radifh, decoctions of mezereon and rhododendron, muftard-feed, and all the terebinthinate fubftances and hot gums. The oil of turpentine itfelf has been much employed, and perhaps conftitutes a part of the celebrated noftrum called the effence of muftard; but our experience of its effects accords with that of Dr. Bardfley, who fays, that, in every form, turpentine was found to be an ungrateful medicine to the ftomach; often impairing the appetite, and not producing, when even duly perfifted in, effects as falutary as the guaiacum and other remedies already mentioned. Neverthelefs, we muft remark, that in different individual inftances, one of thefe remedies will fometimes fucceed when the others have failed, and that therefore none of them fhould be excluded from the catalogue of ufeful expedients.

Some other fubftances have been employed, with occafional fuccefs, in the cure of different cafes of chronic rheumatifm, which do not appear to poffefs any quality in common, and the operation of which, therefore, cannot be fatisfactorily explained. Among thefe we may mention *fulphur*, which has long poffeffed a fort of popular reputation for the cure of lumbago, and fome other varieties of the difeafe. Taken nightly in a confiderable dofe, fo as to act gently upon the bowels, it has fucceeded, in fome inftances, in affording a very fpeedy and marked alleviation of the fymptoms; but, on the other hand, it has very often failed to produce any effect whatever; and under what circumftances thefe refpective variations in its operation occur, we have not been able to afcertain. Another remedy has enjoyed a very high reputation in fome parts of the country, efpecially in Lancafhire; we mean the *cod-liver oil*, or *ling-liver oil;* for it appears that the oil obtained from the liver of either of thefe fifh is equally efficacious. Of this remedy many teftimonies might be adduced in proof of its occafional efficacy in the moft unyielding cafes of chronic rheumatifm. From long and repeated experience, Dr. Bardfley affirms that he is enabled to fpeak of it as a medicine of confiderable but limited powers: in fome inftances, where every other means had proved unfuccefsful, it has operated in a manner fo decidedly beneficial, as to excite aftonifhment; but, on the other hand, he found it to fail often in the more mild and common rheumatic affections. He believes it to be moft beneficial in the chronic rheumatifm of perfons advanced in age, which is accompanied with extreme rigidity of the mufcles, and inflexibility of the joints, in confequence of much expofure to cold and moifture, with hard fare and much fatigue. It was commonly taken in warm table-beer by the hofpital patients, in dofes of half an ounce, or from that to an ounce and a half twice or thrice a day, according to its effects, or to its agreement with the patient's ftomach. Its operation is various, fometimes upon the kidnies, and fometimes upon the bowels; and occafionally it produced an eruption on the fkin: but thefe effects occurred only at the firft taking; for after a fhort continuance, it ceafed to produce any fenfible operation. When it produced relief, this was obvious by the end of a fortnight, and continued flowly to increafe; and in thefe cafes the patients generally began to increafe at the fame time in bulk and fatnefs. Neverthelefs, the objections to the general ufe of this medicine, from its extremely naufeous fmell and tafte, which render it abfolutely intolerable to many ftomachs, however difguifed, and the admiffion of Dr. Bardfley, that it is only to be deemed an auxiliary, and in many refpects inferior to guaiacum, do not lead us to expect that it will ever be generally adopted, notwithftanding its reputation and extenfive employment in the Manchefter Infirmary, where the annual confumption has been nearly fixty gallons for about forty years. Bardfley, loc. cit. p. 22.

As another expedient for the cure of chronic rheumatifm, the *arfenical folution* of Dr. Fowler has been recommended by Mr. Jenkinfon and others. For our own part we have not been fo fortunate as to difcover any remedial properties of this fort in that folution; but from the evidence of two or three cafes adduced by Dr. Bardfley, it appears probable that this medicine is capable of producing very beneficial effects in protracted chronic rheumatifm, where the vital powers are much diminifhed, and the ends of the bones, periofteum, capfules, or ligaments of the joints, are likewife partially affected; though in the milder cafes, where the mufcles and their invefting membranes are the feat of the complaint, it appears to be ufelefs.

External Remedies.—Among the remedies which are ufually employed externally for the cure of chronic rheumatifm, and which, when aided by the adminiftration of medicines internally, have been found moft fuccefsful, are principally the *warm* and *vapour bath*, and various *epifpaftic*, *rubefacient* and *ftimulant* plafters, liniments, and embrocations, employed with or without confiderable *friction*.

The *warm* or *tepid bath*, from the temperature of 85° to 95° of Fahrenheit's thermometer, is very ufeful in foothing pain, and in relaxing the ftiffened joints and rigid fibres of the mufcles, efpecially in elderly patients, whofe ftrength is confiderably reduced by the length and violence of the diforder. But the ufe of a warmer bath, fo as to excite fweating, is apt to induce both local and general debility in protracted cafes, and affords but a temporary relief to the difeafe. But on the whole, the application of the *vapour* of hot water to the furface is a more efficacious remedy. Dr. Bardfley fays, "whenever the joints were found fo rigid as to be nearly immoveable, and the pains upon motion exquifitely

quifitely fevere, or when the mufcles had become contracted and almoft paralytic,—and indeed in every protracted cafe of the difeafe of the hip-joint, *lumbago*, or *fciatica*, the vapour of hot water, locally and properly applied, afforded (efpecially in conjunction with other topical applications) a fafe and often fuccefsful remedy." It may be neceffary to defcribe the mode of employing this vapour. It confifts in conveying the fteam, from a boiler, through tubes of different diameter, fo as to apply it to the different parts of the body. In all obftinate affections of the joints, the author juft quoted obferves, a pipe of nearly half an inch in diameter is to be preferred, and a quarter of an hour is the fhorteft period for its application. In the commencement, however, it is better, as a general rule, to ufe a pipe of fmaller fize, and only to permit the vapour to ftrike upon the affected part at fome diftance from its aperture; for by thefe means an inconvenience will be avoided, which has fometimes prevented the fteady application of the remedy; namely, a confiderable irritation of the fkin from an excefs of heat. By degrees the parts become able to bear a large column of vapour, at a very fmall diftance from the extremity of the pipe; and thus the remedy will be moft likely to produce its full effect. This effect, however, is generally only to be deemed auxiliary, at leaft in obftinate cafes; for it will feldom alone accomplifh the cure.

Among the epifpaftic applications, *bliftering* is commonly reforted to, and often with confiderable benefit, efpecially when the pains appear to be feated only in the fafcia and fuperficial fibres of the mufcles. A repetition of blifters is preferable on the whole, both as productive of lefs diftrefs to the patient, and more benefit to the difeafe, to the practice of keeping the blifter open by a ftimulating ointment. Some authors have recommended *iffues* in preference to blifters, where they could be applied without inconvenience. The excitement of an external inflammation, by the application of the ointment of *emetic tartar*, has been alfo employed inftead of bliftering; and in fome cafes its effects have been highly beneficial.

Rubefacients, or thofe fubftances which ftimulate the cutaneous veffels, and excite a rednefs of the furface by caufing them to be diftended with blood, have been found by the experience of all ages to be capable of removing flight inftances of chronic rheumatifm, and of alleviating the more fevere, efpecially when their operation was aided by *friction*, and by warm or ftimulant plafters. Where the pains are local and permanent, that is, not liable to fhift about from joint to joint, great advantages refult from ftimulating the fkin with an active liniment, and fupporting the excitement by means of a warm plafter. The liniments may be compofed of any ftimulant, oleaginous, fpirituous, or faponaceous liquids: as the common liniment of ammonia and oil, the foap liniment, with camphor, ammonia, tincture of cantharides, or turpentine; and the plafters may be compofed of the gum refins, efpecially ammoniacum, with the acetic acid, or vinegar of fquills, turpentine, plafter of cantharides, &c. Dr. Ferriar's formula, which is borrowed from Dr. Home, and confifted of two drachms of camphor, with an ounce of bafilicon, and half an ounce of black foap, is faid by him to have been very efficacious in the relief of *lumbago*. Thefe liniments fhould be diligently rubbed upon the parts affected, after the fkin has been warmed and irritated by the friction of hot, dry, and coarfe cloths, or the application of the flefh-brufh; or, efpecially in *fciatica* and *lumbago*, during the expofure of the part to the vapour-pipe. By thefe methods the ftimulating effects of the liniments are much increafed, the pain is more effectually relieved, and the cure much accelerated; efpecially when a warm plafter is added to keep up thefe effects. (See Bardfley, loc. cit; and Ferriar's Med. Hift. and Reflections, vol. i. p. 186.) The liniment originally employed by Dr. Home was fpread upon leather, and applied over the difeafed part; he fpeaks, not only from his own experience, but from that of others who had adopted it, of the efficacy of the prefcription. (See Medical Facts and Experiments, part i. fect. 4; and again in his Clinical Experiments and Hiftories, fect. 14.) His formula is perhaps more active than that of Dr. Ferriar, containing cumin feed and ammonia in addition to the camphor, oil of turpentine, and common black foap. But the difpenfatories abound with formulas for the compofition of ftimulating liniments and plafters of fimilar powers.

Among other ftimulants which have been employed for the cure of chronic rheumatifm, efpecially in thofe cafes which are obftinate and of long duration, or are accompanied by confiderable torpor and rigidity, and a diminution of the vital heat, the influence of the *electric* and *galvanic* fluids has been reforted to; and many teftimonies might be adduced in proof of the beneficial operations of both thefe agents. Dr. Bardfley affirms, that the application of electricity by fparks and fhocks, efpecially the former, was manifeftly advantageous; at the fame time he acknowledges, that it was chiefly in conjunction with the local application of vapour, and with tonics and anodynes, adminiftered internally, that the moft marked advantages were produced. For our own part, we have witneffed fo little decided effect from the operation of electricity in any difeafe whatever, that, after a long and frequent ufe of that agent, we have given it up in defpair. Where it produces any effect at all, it is probably by its operation upon the mind of the patient, upon the fame principle as the *metallic tractors* occafionally alleviated pain, (fee IMAGINATION, *Influence of, on the Body*,) and not from any fpecific operation upon the difeafed mufcles.

The operation of mere *friction* affiduoufly employed, either by means of flannel or rough cloths, of the flefh-brufh, or fimply of the hands, or that fort of rubbing or kneading of the body which is called *champooing*, have been often reforted to with confiderable benefit, efpecially in the cafes connected with a paralytic torpor and rigidity of the parts affected. Perhaps, indeed, it is the ftimulus of the friction, to which much of the benefit of liniments and embrocations ought to be afcribed; but as the patient's faith is chiefly fixed upon *medicated* frictions, fo it is generally neceffary to prefcribe them, in order to enfure his perfeverance in the rubbing.

The preceding obfervations have been applied to rheumatifm generally, with only occafional references to the particular forms under which it occurs, fuch as *lumbago*, *fciatica*, *pleurodyne*, rheumatic head-ache, &c. becaufe the treatment is generally applicable to the different fituations of the body in which the difeafe feats itfelf. The principal attention that is requifite to thefe varieties arifes from the r[illegible] fymptoms to thofe of fome other difea[illegible] *[illegible]urodyne*, or rheumatifm affecting the mu[illegible] and the diaphragm, being accompanied with a[illegible]icult refpiration, might be confounded with p[illegible] erroneoufly treated: but in this rheumatic affe[illegible] cheft there is feldom any cough, and no fever, two fym[illegible]oms which are neceffarily prefent in the cafe of pleurif[illegible]ain, the *lumbago* is apt to be miftaken for *nephralgia* [illegible] in the kidnies, connected with inflammation in thefe [illegible]ns, or with the prefence of gravel in them or in the [illegible]s: it may be diftinguifhed, however, from the difeafe[illegible] kidnies, by the circumftances, that the pain does not follow the courfe of the ureters, but ftretches ſtretches rather down the thighs to the toes; that it is chiefly ſevere on aſſuming the erect poſture; that it is not accompanied by ſickneſs or vomiting; and that the urine is not changed in quantity or quality. Dr. Home, and ſome others, have believed that the ſciatica is ſeated in the great ſciatic nerve, or in its ſheath, and the lumbago in the lumbar nerves.

Of *Arthritis rheumatica*, or *rheumatic gout*. This term, though improper, and calculated to miſlead us in our notions reſpecting the nature of the diſeaſe, is retained in conſequence of the want of a more correct appellation. The diſeaſe, in fact, is not a compound of gout and rheumatiſm, but probably rheumatiſm reſembling, in ſome reſpects, the gout in its appearances. It has been called, by an able teacher at a large hoſpital in Southwark, the *rheumatagra*, or *acuto-chronic* rheumatiſm. In ſome caſes, the diſeaſe is merely a partial degree of acute rheumatiſm, affecting only one or two of the ſmaller joints, as the wriſt or even the knuckles, with ſwelling, redneſs, and acute pain. This is often called gout; but as it occurs under circumſtances which differ materially from thoſe under which gout appears, is not preceded by indigeſtion, and does not terminate in the formation of chalk-ſtones, it is obviouſly a different diſeaſe. In many caſes, however, it is the conſequence of acute rheumatiſm, in which the joints laſt occupied by that diſeaſe, eſpecially the ankles and wriſts, remain ſwelled, ſtiff, and painful, and ſometimes œdematous, for many weeks. The pain, in theſe caſes, is generally aggravated at night, or by external heat; but it is accompanied by very little or no feveriſhneſs.

The more acute caſes require nearly the ſame treatment as is employed for the cure of acute rheumatiſm. But when they aſſume more of a chronic form, when the ligaments and membranes of the joints are the peculiar ſeat of the diſeaſe, or an enlargement of the extremities of the bones appears to have taken place, eſpecially in young or vigorous ſubjects, the firſt attempts to relieve ſhould be made by means of *local bleeding*, either by the application of leeches, or, what is perhaps preferable, by the operation of cupping and ſcarifying. Theſe local evacuations ſhould be repeated, if the pain and irritation are not materially relieved; and the good effects may be aided by the application of *bliſters* over the affected joints. Dr. Bardſley ſtrongly recommends the opening of a drain from the parts by means of *iſſues*, made by cauſtic; and affirms that, in obſtinate caſes, which have reſiſted all other means, he has found the happieſt effects from iſſues. The *tepid bath* will often aid the operation of theſe remedies, together with the uſe of mild diaphoretics, followed by tonic bitters, ſuch as the Peruvian bark, chalybeates, the myrrh mixture with ſteel, and the occaſional uſe of antimonials with calomel.

Nodoſity of the Joints.—Before we conclude the ſubject of rheumatiſm, it ſeems neceſſary to notice a ſtate of the joints which is generally deemed rheumatic. Dr. Haygarth, however, obſerves, that it is nearly allied to gout in its character, and in the perſons whom it attacks. Theſe *nodes*, which occur moſt commonly about the fingers, hands, and wriſts, but occaſionally alſo on the knees, ankles, feet, elbows, ſhoulders, and other joints, produce ſtrange diſtortions of the parts, twiſting the fingers, &c. in various directions, and rendering the joints almoſt immoveable. They are not ſeparate tumours, but feel as if they were an enlargement of the bones themſelves. Dr. Haygarth, indeed, is of opinion, that the ends of the bones, the perioſteum, and the capſules or ligaments which form the joints, are the ſeat of this diſeaſe; though he does not appear to have ever examined the matter anatomically. In bad inveterate caſes, he believes that the joints are not merely diſtorted, but diſlocated. The ſwellings are generally painful, eſpecially in the night, though not ſeverely, and often ſore to the touch. In a few patients, a crackling noiſe is perceived in the joints when moved, particularly in the neck. The ſkin is ſeldom, if ever, affected with inflammation. There is one diſtreſsful circumſtance belonging to this diſeaſe, that it has no intermiſſion, and but ſlight remiſſions: for during the remainder of the patient's life, the nodes gradually enlarge, impeding more and more the power of motion. The malady alſo ſpreads to other joints, without producing any alleviation in thoſe which it had previouſly attacked. In one caſe, mentioned by Dr. Haygarth, the fingers, wriſts, knees, ankles, elbows, ſhoulders, neck, and hips, were all affected with this diſeaſe at the ſame time, that is thirteen joints, excluſive of the numerous joints of the hands: if each individual joint of the hands had been taken into the account, they would have amounted to not leſs than forty. In this caſe, the malady had been rapidly advancing for ten years: yet, though theſe nodes, in their gradual progreſs, ſadly embitter the comforts, they do not ſhorten the duration of life: for Dr. Haygarth's firſt patient lived to the age of ninety-three. From the experience of this veteran phyſician it appears, that women are much more frequently the ſubject of nodoſity at the joints than men, and that it commonly firſt begins to ſhew itſelf about the period of the ceſſation of the menſes.

Various remedies have been recommmeded for the relief of theſe nodes; but they have not been found in general to be poſſeſſed of much efficacy. On the whole, the warm bath, a ſtream of warm water, ſuch as the Bath pumping, or a warm *douche* on the nodes, together with the repeated application of leeches, appear to be productive of the moſt decided benefit in this diſeaſe; and the uſe of the leeches appears to conſtitute a very important part of that practice. In bad caſes, from four to ten ſhould be applied to the affected joints once or twice a week. The temperature of the pumping and *douching* ſhould be varied, and that which appears, from the patient's report, to agree the beſt, and to be productive of the moſt decided effect in alleviating the pain and ſwelling, and in improving the power of motion in the joints, ſhould be adopted. This will be found to vary, in different perſons, from 81 to 113 degrees of Fahrenheit's thermometer.

Some authors have conceived that, together with theſe external remedies, the uſe of ſoda, or the vegetable alkali, internally, has been attended with conſiderable benefit. And Dr. Bardſley relates a caſe, in which the continued uſe of mercury, ſo as to excite a moderate ptyaliſm, was apparently remedial. See Haygarth's Clinical Hiſtory of Diſeaſes, pt. ii.; and Bardſley's Reports.

RHEXIA, in *Botany*, derived from ῥῆξις, *a rupture*, or *fracture*, is the ſynonym in Pliny of a plant, reputed to be endowed with numerous virtues, and, amongſt others, with the powers of curing ruptures, or ſimilar complaints. His deſcription leaves us in no doubt as to his plant; ſo far, at leaſt, as its being of the Alkanet tribe, a ſpecies of *Anchuſa*, or perhaps of *Echium*. Why Gronovius and Linnæus choſe this name for the preſent elegant American genus, does not appear.—Linn. Gen. 187. Schreb. 249. Willd. Sp. Pl. v. 2. 301. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 2. 340. Purſh v. 1. 257. Juſſ. 330. Lamarck Illuſtr. t. 283. Gærtn. t. 112.—Claſs and order, *Octandria Monogynia*. Nat. Ord. *Calycanthemæ*, Linn. *Melaſtomæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, oblong, ſwelling in the lower part; limb in four deep, acute ſegments, without any intermediate teeth or ſcales; permanent. *Cor.*

 Petals

Petals four, roundiſh, ſpreading, inſerted into the calyx. *Stam.* Filaments eight, thread-ſhaped, inſerted into the calyx, longer than its limb; anthers declining, furrowed, linear, obtuſe, verſatile, with a curved beak. *Piſt.* Germen roundiſh, ſuperior, unconnected with the tube of the calyx; ſtyle ſimple, the length of the ſtamens, declining; ſtigma oblong, obtuſe. *Peric.* Capſule roundiſh, of four cells and four valves, within the body of the calyx, but unconnected with it. *Seeds* numerous, roundiſh. *Receptacles* four, attached to the central column.

Eſſ. Ch. Calyx with four permanent ſimple teeth. Petals four, inſerted into the calyx. Anthers declining, beaked. Capſule of four cells, within the body of the calyx.

Obſ. For the difference between this genus and Osbeckia, ſee that article.

Willdenow has 17 ſpecies of *Rhexia*, but we have not the means of correctly aſcertaining the generic characters of all of them. They are divided into two ſections, of which the following examples may ſuffice.

Section 1. *Leaves ſeſſile.*

R. *virginica.* Virginian Rhexia. Linn. Sp. Pl. 194. Willd. n. 1. Ait. n. 1. Curt. Mag. t. 968.—Leaves ſeſſile, lanceolate, three-ribbed, with fringe-like teeth. Calyx fringed with glands.—Native of watery places in North America, flowering in July and Auguſt. It ſucceeds tolerably with us, in a bog bed, with plenty of water, but requires ſhelter in winter; nor is it fit for general cultivation; which is much to be regretted, conſidering the great beauty and ſingularity of the large crimſon *flowers*, with their great yellow curved *anthers*. The *root* is fibrous, perennial. *Stem* herbaceous, erect, ſquare, with membranous angles. *Leaves* ſtrongly ribbed, ſmooth, with acute ſlender teeth. *Panicle* forked, ſpreading. *Calyx* brown, beſprinkled with hairs, whoſe points are glandular and viſcid.

R. *mariana.* Maryland Rhexia. Linn. Sp. Pl. 491. Willd. n. 2. Ait. n. 2. (Lyſimachia non papposa, terræ marianæ, &c.; Pluk. Mant. 123. t. 428. f. 1. Lamarck, f. 1?)—"Leaves ſeſſile, lanceolate, three-ribbed, fringed with ſoft hairs. Hairs of the calyx ſtellated."—Found in bogs, and ſandy woods, near waters, from New Jerſey to Carolina, flowering in July and Auguſt. From one to three feet high. *Flowers* handſome, either purple, light red, or pale. *Purſh.*

Sect. 2. *Leaves ſtalked.*

R. *glutinoſa.* Viſcid Shrubby Rhexia. Linn. Suppl. 216. Willd. n. 8.—Leaves ſtalked, oppoſite, elliptical, three-ribbed, ſmooth. Stem ſhrubby. Flowers in terminal, denſe, forked panicles. Calyx ſmooth.—Found in New Granada by Mutis, who ſent fine dried ſpecimens to Linnæus, along with an Indian-ink drawing, cited in the Supplement as a publiſhed work. The whole plant is very handſome, quite deſtitute of pubeſcence, but the *calyx*, and upper ſide of the *leaves*, are extremely glutinous. The *leaves* are rather above an inch long, with three ribs, united above their baſe; the under ſide pale and yellowiſh. *Flowers* copious, large, purple.

R. *inconſtans.* Stitch-leaved Rhexia. "Vahl. Ecl. v. 1. 37." Willd. n. 13. (Oſbeckia ornata; Swartz Ind. Occ. v. 2. 647.)—Leaves ovate, clothed with depreſſed briſtles; pale and three-ribbed beneath. Panicle forked, of few flowers. Calyx rough with ſpreading briſtles.—Native of elevated ſituations on the mountains of Guadaloupe, Nevis, Montſerrat, St. Kit's, &c. among moſs.—The *ſtems* are a foot or two high, erect, branched, rigid, ſquare and briſtly. *Leaves* ovate, a quarter of an inch long, their green convex upper ſide moſt elegantly clothed with ſtrong, depreſſed, yellow briſtles, as if ſtitched with gold thread. *Flowers* purple, uſually five-cleft.

R. *aquatica.* Marſh Rhexia. Swartz Ind. Occ. v. 2. 650. Willd. n. 16. Ait. n. 3. (Melaſtoma aquatica; Aubl. Guian. v. 1. 430. t. 169.)—Leaves oppoſite, heart-ſhaped, minutely crenate, nearly ſmooth. Panicles terminal, three-forked, ſlender, widely ſpreading, many-flowered. —Native of watery places in Guiana and the Weſt Indies. —*Stems* ſhrubby, a yard high. *Leaves* flat, above an inch long, pointed. *Flowers* copious, rather ſmall, white, with purple *ſtamens*. *Calyx* ſmooth.

Rhexia, in *Gardening*, contains plants of the hardy, herbaceous, perennial kind, of which the ſpecies cultivated are; the Virginian rhexia (R. virginica); and the Maryland rhexia (R. mariana).

Method of Culture.—Theſe plants may be increaſed by ſowing the ſeeds procured from their native ſituations, in the autumn or ſpring, in pots filled with good freſh mould, placing them under the protection of frames, or if in a mild hot-bed they will be rendered more forward. When ſown at the latter ſeaſon, the plants ſeldom appear the ſame year. When the plants have attained ſufficient growth they ſhould be planted out partly in a dry ſheltered eaſt border and partly in pots, to have the protection of a frame againſt the froſts in winter. They flower the ſecond year, and with care continue three or four.

And they may be introduced, as they afford ornament, in the borders as well as among flowery potted plants.

RHEXIS, or Rhegma, formed from ῥῆξις, *rupture*, of ῥήγνυμι, *I break*, in *Surgery*, denotes a rupture of the corner of the eye.

RHHENZABERN, in *Geography*, a town of France, in the department of the Lower Rhine; 8 miles S.E. of Landau.

RHIBII, in *Ancient Geography*, a people of Scythia, on this ſide of the Imaus, near the river Oxus, to which belonged the town of Dauaba. Ptolemy.

RHIGIA, a town ſituated in the interior of the eaſtern part of Hibernia, near Rhœbe, according to Ptolemy.

RHIME, or Rime, in *Poetry*. See Rhyme.

RHINANTHUS, in *Botany*, derived from ῥὶν, *a noſe*, or *ſnout*, and ἄνθος, *a flower*, becauſe of its ringent corolla, compreſſed at the upper lip, ſo as to reſemble the ſnout of ſome animal.—Linn. 304. Schreb. 400. Willd. Sp. Pl. v. 3. 188. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 649. Ait. Hort. Kew. v. 4. 2. Purſh 429. Michaux. Boreal.-Amer. v. 2. 17. Juſſ. 101. Lamarck Illuſtr. t. 517. Gærtn. t. 54. (Pedicularis; Tournef. t. 77. Elephas; Tournef. t. 482.)—Claſs and order, *Didynamia Angioſpermia*. Nat. Ord. *Perſonatæ*, Linn. *Pediculares*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, roundiſh, inflated, compreſſed, four-cleft, permanent. *Cor.* of one petal, ringent; tube rather cylindrical, the length of the calyx; limb gaping, compreſſed at the baſe: upper lip helmet-ſhaped, compreſſed, emarginate, narrower; lower ſpreading, flat, trifid half way down, obtuſe, the middle ſegment broader. *Stam.* Filaments four, the length of the upper lip, the two ſhorter ones concealed under it; anthers incumbent, cloven on one ſide, hairy. *Piſt.* Germen ſuperior, ovate, compreſſed; ſtyle thread-ſhaped, longer than the ſtamens, but ſtanding between them; ſtigma obtuſe, inflexed. *Peric.* Capſule obtuſe, erect, compreſſed, of two cells and two valves, gaping at the margins; partition contrary. *Seeds* numerous, compreſſed.

Obſ. Elephas of Tournefort has the margin of the capſule blunt; the ſeeds ſimple; and the calyx unequal, of two lips. It was ſo named from the reſemblance its flowers bear to an elephant's trunk.

Crista-galli of Rivinus has the margin of the capſule extended,

extended, the ſeeds membranous, clothed with wool; and the calyx equal, four-cleft.

Eſſ. Ch. Calyx inflated, compreſſed, four-toothed. Upper lip of the corolla compreſſed. Capſule of two cells, blunt, compreſſed. Seeds imbricated, flat.

1. R. *orientalis.* Linn. Sp. Pl. 840. (Elephas orientalis flore magno proboſcide incurva; Tournef. Voyage, v. 2. 126, with a figure.)—Upper lip of the corolla awl-ſhaped, incurved.—Native of the Levant, on the confines of Perſia, flowering in July.—*Stems* more than a foot high, hollow, ſquare, hairy. *Leaves* oppoſite, on ſhort ſtalks, notched, hairy, veined. *Flowers* on the upper part of the ſtems, fragrant, of a yellow colour, with a brown ſpot on the lower lip and two red ones on the upper. Tournefort reckons this a very ornamental plant.

2. R. *Elephas.* Linn. Sp. Pl. 840. (Elephas Campoclarenſium; Column. Ecphr. 186. t. 188.)—Upper lip of the corolla awl-ſhaped, ſtraight.—Native of ſhady woods in Italy, flowering in May.—This annual is very ſimilar in habit to the laſt, but its *calyx* is trifid, with two of the ſegments recurved, and the third larger, erect, plaited, acute. Tournefort mentions a variety of this which he found on the coaſt of the Black ſea.

3. R. *Criſta-galli.* Yellow Rattle. Linn. Sp. Pl. 840. Engl. Bot. t. 657. Curt. Lond. faſc. 5. t. 43. Mart. Ruſt. t. 148.—Upper lip of the corolla arched. Calyx ſmooth. Leaves lanceolate, ſerrated.—Common in our meadows and paſtures, flowering from June to Auguſt. *Root* annual, fibrous. *Stem* branched, ſmooth, frequently ſpotted. *Leaves* oppoſite, ſeſſile, rough; heart-ſhaped at the baſe. *Flowers* ſomewhat alternate, on ſhort ſtalks, yellow. *Seeds* with a membranous border. The Engliſh name has obtained, from the rattling of its ſeeds in the capſule.

4. R. *Trixago.* Linn. Sp. Pl. 840. (Bartſia Trixago; Sm. Prodr. Fl. Græc. Sibth. v. 1. 427. Trixago apula unicaulis; Columm. Ecphr. 199. t. 197.)—Calyx hairy or downy. Leaves oppoſite, bluntly ſerrated. Stem perfectly ſimple.—Native of Italy, the ſouth of France, and Paleſtine. It flowers in May.—*Root* annual, but throwing out runners. *Stem* more than a foot high, ſtraight, firm, ſquare, rather woolly. *Leaves* long, narrow, pale green, toothed or rather jagged. *Flowers* in large, yellow ſpikes. Ray obſerves that the figure of Columna poſſibly may be a variety of this ſpecies, for it differs in a few ſlight particulars.

5. R. *maximus.* Willd. n. 5. Desfont. Atlant. v. 2. 34.—Lower lip of the corolla longer than the upper; ſegments obtuſe, equal. Calyx villous. Upper leaves alternate, oblong, bluntly toothed. Stem branched.—Native of Crete. We know not of any figure of this ſpecies which is admitted on the authority of Willdenow and Desfontaines.—*Stem* from eighteen inches to two feet high, branched at the upper part, and downy. *Lower leaves* oppoſite. *Flowers* in yellow ſpikes at the tops of the ſtem and branches. This ſpecies has much the appearance of *Bartſia viſcoſa*, of which indeed the *R. maximus* of Lamarck is merely a variety. The ſame author makes the preſent a variety of the following.

6. R. *verſicolor.* Willd. n. 6. Desfont. Atlant. v. 2. 33.—Corolla gaping; lower lip longer than the upper; ſegments obtuſe; the middle one narrower. Calyx villous. Leaves moſtly oppoſite, lanceolate, the upper ones toothed at the baſe. Stem ſimple.—Native of Italy and the north of Africa. This differs from the preceding, in having a ſimple *ſtem*. *Leaves* linear-lanceolate, the upper ones only toothed at the baſe. *Bracteas* ovate, acuminate. *Corolla* only half as large, of a purple colour, the middle ſegment of the lower lip narrower than the other two.

7. R. *capenſis.* Willd. n. 7. (Buchnera africana; Linn. Sp. Pl. 879.)—Calyx downy. Bracteas ovate. Leaves lanceolate, toothed.—Native of the Cape of Good Hope. This is nearly allied to *R. Trixago*, becoming totally black in drying.—The *leaves* have three or four teeth on each ſide, the upper ones ſometimes alternate. *Bracteas* downy, a little pointed. *Calyx* four-cleft, obtuſe as in *Criſta-galli.*

8. R. *indicus.* Linn. Sp. Pl. 841. Fl. Zeylan. 107. Burm. Ind. 131. t. 39. f. 1.—Leaves nearly lanceolate, hairy, entire.—Native of Ceylon.—*Root* annual. *Stem* a ſpan high, erect, ſimple, ſquare, hiſpid. *Leaves* oppoſite, ſmall. *Flowers* ſeſſile, ſolitary, oppoſite, turned to one ſide.

9. R. *virginicus.* Linn. Sp. Pl. 841. Gronov. Virg. 192.—Corolla ſpreading at the throat. Leaves ſinuated and toothed.—Native of Virginia. This plant is nearly akin to *Gerardia*, of which it is moſt probably a ſpecies. The *anthers* are rough with hairs.

10. R. *trifida.* Willd. n. 10. Vahl. Symb. v. 1. 44.—Corolla wide at the throat. Leaves trifid.—Native of ſandy hills in Armenia and Galatia.—*Root* annual. *Stem* ſix inches high, herbaceous, aſcending, quite ſimple, rather downy, round. *Leaves* oppoſite, ſeſſile, downy, ribbed, deeply three-cleft. *Flowers* axillary, ſolitary, oppoſite, ſeſſile.

RHINBERG, in *Geography*. See RHEINBERG.

RHINE, a river which riſes in the Griſon Alps in three branches, which unite into one ſtream. Cæſar is the moſt ancient author who has traced the courſe of this river from its ſource in the Alps to its diſcharge into the ſea. According to this writer it commenced in the territory of the Lepontii; and Pomponius Mela mentions two lakes which it traverſes ſoon after, *viz.* the "Lacus Venetus" and the "Lacus Acronius." Of the deſcriptions given by ancient writers of this river, that of Tacitus is the moſt preciſe and ſatisfactory. The Rhine, ſays this hiſtorian, after having purſued its courſe in one bed, and arriving near the country of the Batavi, divides itſelf into two branches; one of which preſerves its name and the rapidity of its courſe along the borders of Germany until it diſcharges itſelf into the ſea; the other runs towards Gaul, in a larger channel and more tranquil ſtate, and is called by the people of the country "Vahalis," or Wahal. But it ſoon changes this name for that of "Moſa," or Meuſe, and blended with this river diſcharges itſelf into the ocean. Such is the account of Tacitus, to which we ſhall ſubjoin ſome other particulars from ancient writers. The Rhine, which, as we have ſaid, has its ſource in the Alps, aſſumes a northerly direction, and for a conſiderable interval ſeparates Gaul from Germany. At the town of "Burgenatium," or "Quadriburgium," it ſeparated itſelf into two arms or branches; the one flowing northward, and the other towards the weſt. This laſt aſſumed the name of Vahalis (Vahal), and watered the towns of Noviomagus, Grinnes, &c. united with the Moſa or Meuſe, and in this confluent ſtate diſcharged itſelf into the ſea. The other branch, which ran in a northerly direction, watered Arenatium, ſince called Caſtra Herculis; at which place commenced the canal of Druſus, "foſſa Druſiana." Here a new diviſion took place; the canal of Druſus purſued a northerly courſe, and the bed of the Rhine was directed towards the weſt. This laſt watered, beſide other places, Batavodurum, Trajectum, Lugdunum Batavorum, and emptied itſelf into the ſea, at a place called "Caſtellum Romanum." We ought, however, to obſerve, that near Trajectum it furniſhed a ſmall branch which had a northern courſe. The canal of Druſus flowed northwards, and it is now called the Yſſel. This canal, before it reached the ſea, traverſed a ſmall lake called Flevo, from which iſſued a ſmall a small river of the same name, which ran towards the sea in a northerly direction, and discharged itself into it near a place called "Castellum," which defended the entrance of this river. The lake just mentioned is considerably enlarged, and communicates with the sea under the name of Zuider-zee. The Rhine has been almost always regarded by the Romans as the boundary of their empire between Gaul, which they had conquered, and Germany, into which they made frequent incursions. According to modern accounts of the course of the Rhine, it commences, as we have said, in the Alps of the Grisons in three branches, which afterwards unite into one stream. The principal branch descends from the mountain of St. Gothard, and runs into the lake of Constance, near Rheineck; traversing the lake of Constance and Zell, it passes near Stein, Schaffhausen, Eglisau, Keiserstuhl, Seckingen, Rheinfelden, Bâle, Huningue, Strasburg, Spire, Worms, Oppenheim, Bingen, Mentz, St. Goar, Coblentz, Bonne, Cologne, Zons, Nuys, Dusseldorp, Duysberg, Rees, and Emeric, a little below which a large branch separates to the left, and takes the name of Wahal; it then proceeds to Huissen and Arnheim, near which another branch breaks off to the right and joins the Issel. The stream that still maintains the name of Rhine passes on to Wageningen, and Wyck le Duerstede, where it is again divided. The larger part to the left takes the name of the Leck and joins the Meuse; the smaller and less branch passes by Utrecht, Voerden, Leyden, &c. and loses itself at last in the sand, just before it reaches the German sea, a few miles after it has left Leyden. By the treaty of Paris in 1814, the Rhine is to remain as the boundary of France and Germany, and the main stream of this river constitutes the frontier, provided however that the changes that may hereafter take place in the course of that river shall not affect the property of the islands.

RHINE is also a river of Brandenburg, which runs into the Havel, 10 miles above Havelburg.—Also, a river of France, which runs into the Loire, near Roanne.

RHINE, *Circle of the Lower*, a division of Germany, bounded by the circles of Westphalia, Upper Rhine, Franconia, and Swabia, and by the duchy of Luxemburg and France. In conjunction with the circle of the Upper, it is said to contain 960 square German miles. The states of this circle were the electors of Mentz, Treves, and Cologne, together with the Palatine, the duke of Aremberg, the prince of Taxis, the Teutonic bailiwic of Coblentz, the prince of Nassau-Dietz, on account of the seigniory of Beilstein, the elector of Treves, on account of Lower Isenburg, and the count of Sinsendorf, on account of the burgraviate of Rheineck. The claim of the town of Gelnhausen was disputed. The summoning prince and director of the circle was the elector of Mentz. The diets of the circle have ever since the middle of the 17th century been held at Francfort on the Mayn. This circle was one of those called the "anterior circles," but which, in the years 1697 and 1702, formed with each other a mutual compact for defence against the attacks of an enemy. This compact continued, and the circle always appointed its quota of horse and foot; which quota, as well as the contribution of the circle to the aid of the empire, was generally equal to that of the circle of the Upper Rhine. In regard to religion, this circle was reckoned among the mixed.

RHINE, *Circle of the Upper*, was bounded by the circles of the Lower Rhine, Westphalia, Upper and Lower Saxony, Swabia, and Franconia, and by those of France, formerly called Alsace and Lorraine, in the latter of which were some lands belonging to this circle. The states belonging to this circle were the bishoprics of Worms and Spire, with the provostship of Weissenburg, Strasburg, Bâle, and Fulda, and the commandery of the order of St. John, and also the princely abbey of Prum, with the provostship of Odenheim, and the electorate palatinate of Simmern, Lautern and Veldenz, the palatinate of Deux-Ponts, Hesse-Cassel, Hesse-Darmstadt, Hersfeld or Hirschfeld, and Sponheim, the margraviates of Nomeny, Salm with Kirburg, Nassau-Weilburg, Nassau-Usingen, Nassau-Idstein, Nassau-Saarbrucken, and Otweiler, together with those of Waldeck, Hanau-Munzenberg, Hanau-Lichtenburg, Solms-Hohensolms, Solms-Braunfels, Solms-Ruddheim, Solms-Laubach, and the electorate of Mentz on account of Konigstein, that of Stolberg on account of the same, those of Isenburg-Birstein, Isenburg-Badingen, Washtersbach, and Mucholz, Grewiler, Grunbach, Dhaun, Leinengin-Hartenburg, Leinengin-Westerburg, and Grunstadt, Munzfelden, Witgenstein of Witgenstein, Witgenstein-Berleburg, Falkenstein, Reipolzkirchen, Creange, Wartenburg, Bretzenheim, Dachstuhl, and Ollbruck, and the imperial cities of Worms, Spire, Francfort, Friedburg, and Wetzlar. The bishop of Worms, and the elector palatinate for the duchy of Simmern, were summoning princes of this circle. The diets of the circle of the Upper Rhine were formerly held at Worms, but in the last century at Francfort; but the chancery circle of the archives belonging to it were kept at the directory at Worms. This circle, with regard to religion, was reckoned among the mixed, and to the chamber judicatory actually presented two assessors.

RHINE, *Lower*, one of the ten departments of the N.E. region of France, bounded on the N. by the departments of Mont Tonnerre and the Moselle, on the E. by the Rhine, on the S. by the department of the Upper Rhine, and on the W. by the departments of the Vosges, the Meurthe, and the Moselle, situated on the left bank of the Rhine, in N. lat. 48° 45′, containing 5695 kiliometres, or 288 square leagues, and 444,858 inhabitants, and divided into four districts, including 37 cantons, and 616 communes. The four districts or circles are, Wissembourg, including 113,786 inhabitants, Saverne with 78,398, Strasbourg with 155,647, and Barr with 97,027 inhabitants. According to M. Hassenfratz's statement, its extent in French leagues is 30 in length, and 15 in breadth. The number of circles is 5, and of cantons 30, and its population 415,080. Its contributions to the land-tax, &c. in the 11th year of the French era, amounted to 3,609,442 francs; and its expences, administrative, judiciary, and for public instruction, amounted to 359,740 fr. 33 cents. The capital of this department is Strasbourg, and it comprehends that district which, before the revolution, was Lower Alsace. As it lies between mount Vosges and the Rhine, it is diversified with eminences and plains, producing grain, wine, fruits, tobacco, saffron, and also with forests and plains.

RHINE, *Upper*, one of the ten departments of the N.E. region of France, bounded on the N. by the department of the Lower Rhine, on the S. by Switzerland, and on the W. by the departments of the Upper Saone and Vosges, situated on the left hand of the Rhine, in N. lat. 47° 40′, containing 6030 kiliometres, or 280 square leagues, and 382,285 inhabitants, and divided into five districts, or circles, including 39 cantons, and 703 communes. The five districts are Colmar, comprehending 144,821 inhabitants; Altkirch, 83,515; Delemont, 35,779; Porentruy, 34,910; and Befort, 83,260. According to the statement of M. Hassenfratz, its extent in French leagues is 24 in length, and 14 in breadth: its circles are 3, its cantons are 25, and its population consists of 283,252 persons. Its contributions to the land-tax, &c. in the

the 11th year of the French era, amounted to 2,837,063 fr. and its expences, adminiftrative, judiciary, and for public inftruction, amounted to 354,279 fr. Its capital is Colmar, and it is compofed of Upper Alface, Sundtgaut, Porentruy, and a part of the bifhopric of Bâle. The foil is in fome parts moderately fertile, and in others yields all forts of grain, wine, and paftures. It has mines of filver, copper, lead, iron, and coal, with mineral fprings.

Rhine, *Confederation of the*, now abolifhed. See Confederation, &c.

Rhine *and Mofelle*, one of the thirteen departments of that region of France called the Reunited country, bounded on the N. by the department of the Roer, on the E. by the Rhine, on the S. by the departments of Mont Tonnerre and the Saone, and on the W. by the departments of the Sarre and the Roer; fituated in N. lat. 50° 15′, and formed of a part of the electorate of Treves, S. of Roer, and on the left hand of the Rhine. Its territorial extent is 4860 kiliometres, or 290 fquare leagues, and the number of inhabitants is 203,290. It is divided into three circles or diftricts, including 30 cantons, and 675 communes. The diftricts are Coblentz, containing 69,900 inhabitants; Bonn, 70,508; and Simmern, 62,882. According to Haffenfratz, its extent in French leagues is 25 in length, and 12 in breadth: it contains 3 circles, and 30 cantons, and a population of 372,000 perfons. Its contributions to the landtax, &c. in the year 11, amounted to 1,717,463 fr.; and its expences, adminiftrative, judiciary, and for public inftruction, were 239,883 fr. 33 cents. The capital of this department is Coblentz. Several tracts in it are hilly and wooded; and others, though but indifferently fertile, produce confiderable crops of grain, flax, hemp, wine, fruits, and paftures. It has mines of iron, quarries of marble, ftone, &c.

Rhine, in *Ichthyology*, a name given by Ariftotle, Appian, and moft of the Greek writers, to that fpecies of the fqualus, which we ufually call the *fquatina*: the *fquatus* of Ifidore and Pliny. Artedi has diftinguifhed this from all the other fpecies of the fqualus, by the having no pinna ani, and the mouth in the extremity of the fnout. See Squalus.

RHINE-GRAVE, in Germany, a count palatine of the Rhine. See Grave and Palatine.

RHINE-LAND Rod, in *Fortification*, &c. a meafure of two fathom, or twelve feet, ufed by the Dutch and German engineers, &c.

RHINENCHYTES, in *Surgery*, a fyringe for the nofe.

RHINFELS, in *Geography*, a town and fortrefs of Germany, in the county of Catzenelnbogen, near St. Goar.

RHINGAU, or Rheingau, a tract of country along the Rhine, in the electorate of Mentz, extending from Baccharach to Mentz, celebrated for its excellent wine.

Rhingau, in *Ichthyology*, the name given by fome authors to the lavaretus, a fmall fifh caught in the German lakes, and fent in pickle into many parts of the world.

RHINHEIM, in *Geography*. See Reinheim.

RHINIUM, in *Botany*, a name given by Schreber, in his Genera, 701, to the *Tigarea* of Aublet, Lamarck Illuftr. t. 826; but in his addenda, 833, referred to Tetracera; fee that article hereafter.

RHINOBATOS, in *Ichthyology*, the name of a flat cartilaginous fifh, of the fquatina or monk-fifh kind, but differing from it in this, that the body is proportionably longer, and the head is more pointed; and the mouth is a great way below the end of the fnout, and placed under the head. It is from three to four feet long, and is common in the Mediterranean, and brought to market in fome parts of Naples. This is a fpecies of ray in the Linnæan fyftem. See Raia.

RHINOCEROS, in *Zoology*, a genus of the clafs Mammalia and order Bruta, of which the generic character is, horn folid, perennial, conic, placed on the nofe, not adhering to the bone. There are two

Species.

Unicornis; One-horned Rhinoceros. The one horn of this animal marks the fpecies. It inhabits marfhy places between the tropics; lives on thorns and fpinous plants; it may be tamed, and becomes mild, but when enraged it will overturn trees with its violence; its fight is weak, but its hearing and fmell are very acute.

In the year 1739 we had a young rhinoceros with one horn fhewn in England, of which Dr. Parfons has given a very accurate account in the Philofophical Tranfactions, N° 470. p. 523, &c. or Abridg. vol. ix. p. 94, &c.

The creature fed on rice, fugar, and hay; his keeper ufed to mix the rice and fugar in the following manner: feven pounds of rice and three pounds of fugar made the provifion for one day; he eat this at three meals; and befides this he eat about a trufs of hay every week, and a large quantity of greens that were brought to him at different times, and of which he feemed more fond than of dried food. He drank often, and always fwallowed a large quantity of water at a time.

He appeared very peaceable in his temper, and bore to be handled on any part of his body with great patience, except when he was hungry; but he was then always outrageous, as alfo when he was ftruck. His moft violent paffions, even on the laft occafion, were however always immediately appeafed by giving him victuals.

Notwithftanding the lumpifh afpect and heavy make of this creature, he would jump about very nimbly in his fits of paffion, and often leap to a great height; and one common mark of his fury was the ftriking his head againft the walls, or any thing elfe that was in the way, and this he would do with terrible violence. He was very apt to fall into thefe paffions in a morning, before his rice and fugar were given him, and from the whole he appeared quite untractable, and feemed able, in his paffions, to have run fo faft, as that a man on foot could not have efcaped him.

This creature was two years old, and did not exceed a young heifer in height, but was remarkably broad and thick. His head was very large; and the hinder part of it, near the ears, remarkably elevated above the reft of the face, which was flat, and funk down in a remarkable manner in the middle, rifing again towards the origin of the horn, but in a much fmaller degree.

The horn in this young animal did not rife above an inch high from its tough bafis (though in full grown animals it is fometimes three feet and a half long), and was black and fmooth at the top, but ragged downwards; and the determination of its growth is backward, not ftraight up; this is very evidently feen in the horns of old rhinocerofes, which are always curved in a confiderable degree that way. If we confider the proportion of this animal's fize to the length of its horn, and thence carry the proportion to that between the large horns we fee in the mufeums of the curious, we muft fuppofe the animal of a very ftupendous fize, when at its full growth.

The fides of the under-jaw in this creature ftand very wide afunder, flanting outward to the lower edge, and backward to the neck; the edges turn outwards from this ftructure of the bones, and the head neceffarily looks very large. The rhinoceros has four cutting teeth, one on each corner

corner of each jaw, and fix grinders in each; the firft remote from the cutting teeth. That part of the head which reaches from the fore-part of the horn to the upper lip, may be called the nofe: this is very thick and bulky, and has a kind of circular fweep down towards the noftrils; on all this part there is a great number of rugæ or wrinkles.

The noftrils are fituated very low, in the fame direction with the opening of the mouth, and not more than an inch from it; and, when viewed in a fore-view, the whole nofe, from the top of the horn to the verge of the lower lip, is fhaped like a bell. The under lip is like that of an ox, but the upper more like that of a horfe, and he ufes it as that creature does, to gather up hay from the rack, or grafs from the ground; but with this fuperior advantage, that this creature has a power of extending this lip to fix or feven inches in length from the nofe, and there drawing it to a point: with this lip, thus extended, the creature is able to grafp a ftick, or any fmall fubftance, and hold it extremely faft; and this power of prolonging the lip ferves, in many purpofes, to the fame end as the trunk of that other unwieldy animal, the elephant.

The tongue of the rhinoceros is faid to be fo rough as to be able to rub a man's flefh off from the bones; but in this young fubject it was fo foft, that it refembled that of a calf. It may poffibly grow harder with age; but the ftory of its effects feems of a piece with the many other falfe marvels reported of this animal. The eyes are dull and fleepy, much like thofe of a hog in fhape; he feldom opens them entirely; and it is to be obferved, that they are fituated nearer the nofe than thofe of any other known quadruped. The ears are broad and thin towards the top; the neck is very fhort; the fhoulders are thick and heavy; the body is thick, and juts out at the fides, and has a hollow in the back; the belly hangs low; the legs are fhort, thick, and ftrong; the hoofs are divided into three parts, each pointing forward; the tail is flender, flatted at the end, and covered on the fides with very ftiff thick black hairs; the fkin is naked, rough or tuberculated, lying about the neck in vaft folds; there is another fold from the fhoulders to the fore-legs, and another from the hind part of the back to the thighs. The fkin is thick, and feems almoft impenetrable, infomuch that it will turn the edge of a fcymitar, and refift a mufket-ball; it feels like a piece of board of half an inch thick. It is covered in all parts, more or lefs, with a fort of incruftations, refembling fcales. Thefe are fmall on the neck, and largeft of all on the fhoulders and hips; between the folds of this thick fkin, the cuticle, which is left bare, is foft and eafily penetrable. The fcabby incruftations of the fkin have been called fcales by fome writers; but this is a very wrong term, for they have nothing of the nature of fcales, nor any thing of regularity in them.

The creature is of the retromingent, and therefore probably of the retrogenerative kind. Thofe animals that have been brought to Europe have been young and fmall; but, according to Bontius, they equal the elephant in the bulk of their bodies, though they are lower, on account of the fhortnefs of their legs. They inhabit Bengal, Siam, Cochinchina, Quangfi in China, and the ifles of Java and Sumatra. They are fond of fhady forefts, the neighbourhood of rivers, and marfhy places; and are fond of wallowing in the mud like the hog. The rhinoceros is a folitary animal, brings one young at a time; is quiet and inoffenfive, but furious when provoked; very fwift and dangerous; and, though dull of fight, has a moft exquifite fmell. It grunts like a hog. The flefh of this animal is eaten. The fkin, flefh, hoofs, teeth, and dung itfelf, are ufed in India medicinally. The horns are in great repute as an antidote againft poifon, efpecially thofe of the virgin female, called abbada; cups of which are faid to communicate virtue to the liquor poured into them. Redi, who has been very fagacious in difcovering the falfity of many of the pretended medicines taken from animals, yet gives us, on the teftimony of his own experience, an account of fome very remarkable virtues in the parts of the rhinoceros. The blood, he affures us, is excellent in colics and in dyfenteries. The decoction of the fkin, he affures us, is a grand ftomachic antidote; and the horns are very valuable and alexipharmic.

This animal is the unicorn of fcripture, and the Indian afs of Ariftotle, who fays it has but one horn.

Bicornis; Two-horned Rhinoceros. This fpecies inhabits Africa, but, according to Pallas, the bones of it are found buried in the north of Ruffia. Its flefh refembles that of a hog; the vifcera thofe of a horfe; the fecond horn is fhorter, and placed over the firft; it has no gall-bladder, and no fore-teeth; the fkin is without folds, granulated, and of a deep afhen-grey; between the legs it is fmooth, and flefh-coloured; in other parts there are a few briftles, but they are moft numerous about the ears and end of the tail. This animal inhabits Africa only; and feems, in its manners, to agree with the former. The mifchief it does is more the effect of a fenfelefs impulfe than of rage; for, though its fight is bad, its fenfes of hearing and fmelling are exquifite, fo that the leaft noife or fcent puts it in motion; and in running to the fpot from which the alarm proceeds, it overturns and tramples on animals, or any thing elfe which it meets with in its way, but never ftays or returns to renew the charge. There is a variety, but not often feen, that has three horns; the third being an excrefcence on one of the others.

Mr. Bruce's defcription of the manner of feeding, as well as of fome other particulars relative to the two-horned rhinoceros, feems highly worthy of notice. He informs us, that "befides the trees capable of moft refiftance, there are, in the vaft forefts within the rains, trees of a fofter confiftence, and of a very fucculent quality, which feem to be deftined for his principal food. For the purpofe of gaining the higheft branches of thefe, his upper lip is capable of being lengthened out, fo as to increafe his power of laying hold with this, in the fame manner as the elephant does with his trunk. With this lip, and the affiftance of his tongue, he pulls down the upper branches which have moft leaves, and thefe he devours firft. Having ftript the tree of its branches, he does not therefore abandon it; but, placing his fnout as low in the trunk as he finds his horns will enter, he rips up the body of the tree, and reduces it to thin pieces, like fo many laths; and when he has thus prepared it, he embraces as much of it as he can in his monftrous jaws, and twifts it round with as much eafe as an ox would do a root of celery, or any fuch pot-herb or garden-ftuff.

"When purfued, and in fear, he poffeffes an aftonifhing degree of fwiftnefs, confidering his fize, the apparent unwieldinefs of his body, his great weight before, and the fhortnefs of his legs. He is long, and has a kind of trot, which, after a few minutes, increafes in a great proportion, and takes in a great diftance; but this is to be underftood with a degree of moderation. It is not true, that in a plain he beats the horfe in fwiftnefs. I have paffed him with eafe, and feen many worfe mounted do the fame; and though it is certainly true that a horfe can very feldom come up with him, this is owing to his cunning, but not his fwiftnefs. He makes conftantly from wood to wood, and forces himfelf into the thickeft part of them. The trees that are dry are broke down, like as with a cannon-fhot, and fall behind him,

him, and on his side, in all directions. Others that are more pliable, greener, or fuller of sap, are bent back by his weight, and the velocity of his motions; and, after he has passed, restoring themselves like a green branch to their natural position, they sweep the incautious pursuer and his horse from the ground, and dash them in pieces against the surrounding trees.

"The eyes of the rhinoceros are very small, and he seldom turns his head, and therefore sees nothing but what is before him. To this he owes his death, and never escapes, if there is so much plain as to enable the horse to get before him. His pride and fury then make him lay aside all thoughts of escaping, but by victory over his enemy. He stands for a moment at bay; then, at a start, runs straight forward at the horse, like the wild boar, whom, in his manner of action, he very much resembles. The horse easily avoids him, by turning short to a side; and this is the fatal instant: the naked man, with the sword, drops from behind the principal horseman, and, unseen by the rhinoceros, who is seeking his enemy, the horse, he gives him a stroke across the tendon of the heel, which renders him incapable of further flight or resistance.

"In speaking of the great quantity of food necessary to support this enormous mass, we must likewise consider the vast quantity of water which he needs. No country but that of the Shangalla, which he possesses, deluged with six months' rain, and full of large and deep basons, made in the living rock, and shaded by dark woods from evaporation, or watered by large and deep rivers, which never fall low or to a state of dryness, can supply the vast draughts of this monstrous creature. But it is not for drinking alone that he frequents wet and marshy places: large, fierce, and strong as he is, he must submit to prepare himself against the weakest of all adversaries. The great consumption he constantly makes of food and water necessarily confine him to certain limited spaces; for it is not every place that can maintain him. He cannot emigrate, or seek his defence among the sands of Atbara."

The rhinoceros with two horns was the species described by Martial, under the name of *rhinoceros cornu gemino*, who relates its combat with the bear.

> "Namque gravem gemino cornu sic extulit ursum,
> Jactat ut impositas taurus in astra pilas."
> Spect. Epig. 22.

The Romans, who procured their rhinoceroses from Africa, represent them with double horns. That figured in the Prenestine pavement, and that in a coin of Domitian, have two horns; that which Pausanias describes (ix. 9.) under the name of Ethiopian bull, had one horn in the nose, and another lesser higher up; and Cosmas Ægyptius (tom. ii. 334.), who travelled into Æthiopia, in the reign of Justinian, also attributes to it the same number. Augustus introduced a rhinoceros (probably of this kind) into the shows, on occasion of his triumph over Cleopatra. Dion Cassius, lib. ii. Phil. Trans. abr. vol. ix. ubi supra. Id. vol. lvi. p. 32, &c.

M. Geoffroy of France thinks there are, or at least have been, no less than five different species of the rhinoceros; *viz.* 1. The rhinoceros africanus, cornu gemino of Camper, who has given a figure of the skull in the Petersburgh Transactions for 1777. 2. The species found fossile in Siberia, which M. Geoffroy contends is different from the common two-horned rhinoceros, though of that division of the genus. 3. That of which the skull is figured by Camper, and described by him in a letter to Dr. Pallas, in the Petersburgh Transactions. This is a single-horned species, and has been often confounded with the common rhinoceros. 4. The common single-horned Asiatic rhinoceros. And, 5. The Sumatran rhinoceros, described by Mr. Bell in the Phil. Trans. of the Royal Society of London.

RHINOCEROS *Avis*, in *Ornithology*, the rhinoceros-bird, a name given by authors to a species of Indian raven, called by others *corvus Indicus cornutus*; the beak of which is frequently brought over into Europe. This, in the Linnæan system, is a species of *Buceros*; which see.

It is a very ugly bird, and of a very rank smell. It much exceeds the European raven in bigness, and its head and neck are very thick. Its eyes are very large, and its beak of a very remarkable figure, having a large and thick horn-like protuberance on its upper part. The whole beak is bent like a bow, not hooked at the end like the beaks of the hawk, &c. It is of a yellowish-white below, and on the upper part towards the head is of a fine gay red, and the rest of a yellowish-white; the upper chap is serrated. The horn grows out from the head with this, and runs along it, and bends up at its extremity; its upper and under part are red, its middle yellow. The bird feeds on carrion.

RHINOCEROS, in the *History of Insects*, a species of beetle, so called, because it has a kind of horn upon its head.

RHINOCOLURA, or RHINOCORURA, in *Ancient Geography*, a town of Syria, 22 miles from Raphia, and which formed a kind of boundary between Syria and Egypt. Strabo attributes it to Phœnicia; and Pliny calls the sea, on a strait of which this place is situated, the "Sea of Phœnicia." Diodorus Siculus says, that this town, situated on the confines of Egypt and Syria, near the sea, was destitute of all the conveniencies of life; that its water was bitter and noxious, and that it was surrounded with salt marshes. It was in the vicinity of this place that the Israelites were nourished with quails.

RHINOMACER, in *Entomology*, a genus of insects of the order Coleoptera. The generic character is, antennæ setaceous, seated on the snout; it has four feelers, growing thicker towards the end; the last joint is truncate. There are three species, none of which are found in this country.

Species.

CURCULIOIDES. This is grey and downy; the antennæ and legs are black. It inhabits Italy. It resembles a curculio. The antennæ are setaceous and black, and as long as the thorax; the last joint is sharp; the snout is flat, and impressed in the middle.

ATTELABOIDES. This is piceous-downy; the antennæ and legs are testaceous. It is found in divers parts of Sweden. The snout is elevated and projected; the body is cinereous.

CÆRULEUS. This species is of a blueish colour, and it is subvillous; the base of the antennæ and legs are yellow, It inhabits Calabria, and has been thought to be a species of the *Attelabus*; which see.

RHINOPTES, a word used by the ancients to express a person, who, from an ulcer in the great canthus of the eye, laying open the passages to the nose, can see through his nostril.

RHINOW, in *Geography*, a town of the Middle Mark of Brandenburg, on the Rhine; 20 miles N. of Brandenburg.

RHINSBERG. See REINSBERG.

RHINSBERGERS, in *Ecclesiastical History*. See COLLEGIANS.

RHIPÆI MONTES, in *Ancient Geography*. See RIPHÆAN *Mountains*.

RHIPSALIS, in *Botany*, Gærtn. t. 28. (See CACTUS, sp. 25.) It is curious to observe how the representation of the fructification of this plant, in Miller's Illustration of the Linnæan system, is made to answer to the generic character of *Cassytha*, for which it had been erroneously taken.

RHIPTASMOS, a word used by the ancients to express prefs a reftleffnefs and frequent toffing about, a very common fymptom in fevers.

RHISOPHAGI, in *Ancient Geography*, a people of Ethiopia, in the vicinity of the ifle of Meroe, upon the banks of the rivers Aftaboras and Aftapas, according to Diodorus Siculus.

RHISPIA, a town of the Higher Pannonia, at a diftance from the Danube, and fituated between Savaria and Vincendria. Ptolemy.

RHISUS, a town of Greece, on the coaft of Theffaly, according to Strabo and Steph. Byz. Pliny mentions a town of this name in Magnefia.

RHITHYMNA, a town fituated on the northern coaft of the ifle of Crete. Ptolemy.

RHITIA, a town of Africa, in Mauritania Cæfarienfis; placed by Ptolemy in the interior of the country between Arina and Victoria.

RHITTIUM, a town of Lower Pannonia, upon the banks of the Danube, between Acumincum Legio and Taururum, according to Ptolemy.

RHIUM, a promontory on the N.E. part of Achaia: it formed with Anti-Rhium, another promontory oppofite to it, and more northerly, the ftrait by which the Ionian fea communicated with the gulf of Corinth.—Alfo, a town of the Peloponnefus, in Meffenia, upon the gulf of Thuriates, oppofite to the promontory Tanarus, according to Strabo.—Alfo, a promontory on the E. fide of the ifland of Corfa, between mount Rhætius and the town Urcipium. Ptolemy.

RHIUSIAVA, a town of Germany, on the banks of the Danube, between Aræ Flaviæ and Alcimænis. Ptolemy.

RHIW-ABON, or RUABON, in *Geography*, a market-town in the cwmwd of Maelor Gymraeg, cantref of Uwck-Nant, (now called the hundred of Bromfield,) county of Denbigh, North Wales, is fituated on rifing ground, at the diftance of four miles S.S.W. from the town of Wrexham. The market-day here is Monday, weekly; befides which, there are fairs on the laft Friday in February, the 22d of May, and the 20th of November. The petty feffions for the Ruabon divifion of the hundred are held in this town. The church is an ancient ftructure, but is in good repair, and contains feveral monumental erections. One, to the memory of the firft fir Watkin Williams Wynne, difplays a figure of the deceafed in a loofe robe. On one fide is a figure of his fon, and on the other that of his daughter, both in kneeling poftures. This monument was erected by Ryfbrack. Near it ftand thofe of the late fir Watkin Williams Wynne, bart., and his lady; both of them the workmanfhip of Nollekens, and worthy of his chafte and claffic chiffel. The latter exhibits lady Wynne in the character of Hope, ftanding, and reclining her arm on an urn; the whole being placed upon a pedeftal, made in the fhape of a Roman altar. The other principal monuments commemorate Henry Wynne, efq., tenth fon of fir John Wynne of Gwidir, who died in 1671; fir John Wynne of Wynftay, and his wife Jane; and another fir John Wynne, fon of the above, with his wife, the heirefs of Watftay. In a chapel, on the fouth fide of the communion table, is likewife an altar tomb, fupporting the recumbent figures of a man in armour, and a female habited in a mantle. From an infcription round the edge of the entablature, it appears that thefe reprefent John ap Ehs Eyton, efq., who died in 1526, and Elizabeth Caffley, his wife, who died in 1524.

Rhiw-Abon is noted as the birth-place of Dr. David Powell, who tranflated into Englifh the Hiftory of Wales, written by Caradoc of Llancarfan, with the Continuation by Humphrey Llwyd; and who likewife firft edited the works of Giraldus Cambrenfis, and publifhed a treatife, entitled "De Britannica Hiftoria recte intelligenda." He died in 1590. This parifh is very extenfive, and contains five townfhips. The town confifts, according to the population returns of 1811, of 263 houfes, and 1137 inhabitants. The parifh abounds with collieries, the produce of which is conveyed to different parts of the country, by means of the Ellefmere canal, which paffes near the town, and forms a junction with the canals that penetrate Wales on the one fide, and communicate with the Grand Trunk Navigation on the other. Adjoining Rhiw-Abon is Wynnftay-hall, the feat of fir Watkin Williams Wynne, bart. The houfe is large, but, owing to the heterogeneous and patched character of its architecture, it poffeffes little elegance of external appearance. The apartments in the interior, however, are grand and fpacious, and contain feveral good portraits of the Wynnes, the Williamfes, and the Seymours, painted by Vandyke, fir Godfrey Kneller, and other eminent artifts. Clofe to the houfe is a building, originally fitted up as a theatre, but now appropriated for an annual agricultural meeting, auxiliary to the fociety at Wrexham. A fhow of cattle takes place on the occafion of each meeting, at which premiums are adjudged for the beft fpecimen of every fpecies of ftock, and alfo for other hufbandry improvements. This eftate was anciently the refidence of Madoc ap Gryffydd Maelor, lord of Bromfield, and founder of Valle-Crucis abbey. From the circumftance of the ancient rampire, called Watt's Dyke, running through the park, it was long denominated Watftay-park, in allufion thereto. It extends above eight miles in circumference, and is ornamented with plantations, a fine lake, and various buildings. Among the objects of the laft mentioned kind is a column, 100 feet high, built of free ftone, from a defign by the late Mr. Wyatt. It was erected as a tribute of maternal affection, in memory of fir Watkin Williams Wynne, father to the prefent baronet. In another part of the grounds is a tower, or rotunda, intended to commemorate the heroes of the Cambrian legion, who fell in the caufe of loyalty, under fir Watkin, during the late rebellion in Ireland. The fpot on which this tower is fituated commands an extenfive view of mountains, woods, and the meanderings of the Dee. The valley, watered by that river here, difplays the moft picturefque and romantic fcenery, whofe beauties peculiarly excited the admiration of the celebrated lord Lyttelton. The turnpike-road from Rhiw-Abon to Ofweftry, which croffes this valley, is formed for nearly two miles on the embankment of Offa's Dyke. It is here ten feet high, and broad enough for two carriages to run abreaft. Near this road is a remarkable tumulus, fuppofed to be the burying-place of fome chieftain flain in a battle, fought in this neighbourhood, about the year 1161, between Owain Cyfeiliog, prince of Powys, and the Englifh, and terminated in favour of the ancient Britons. This victory gave rife to the beautiful poem, called "Hirlas Owain," or the Drinking-Horn of Owain, compofed by the prince himfelf; which, according to Mr. Pennant, ranks with the beft Pindaric ode of the Grecian fchool. About three miles northward from Rhiw-Abon is Erdigg, or Erddig, the feat of Simon Yorke, efq. The houfe, which has been lately modernized, contains fome valuable paintings; and the library is the depofitory of many curious Welfh MSS., including the Seabright collection. The grounds are laid out with much tafte, but the efforts of art are too apparent. The continuation of Watt's Dyke extends acrofs thefe grounds, running along one fide of a bank between the two vallies, by which the domain is bounded. Not far from hence are the fragments of a cemented wall, and various foundations of buildings, furrounded by a triple intrenchment of a pentagonal form. Thefe

These are supposed by some to be of Roman origin, but others conceive that they mark the scite of a Saxon fort, constructed by the Mercians to defend their line of demarcation, as fixed by the great Offa. This last opinion is rendered the more probable, by the fact of there being some vestiges of a similar fort more to the northward, and on the same line. Philip Yorke, esq., ancestor to the present proprietor of Erddig, was author of "The History of the five royal Tribes of Wales;" a work abounding with so much information, that it is greatly to be lamented that he did not favour the world with his intended Stemmata, or Fifteen Tribes.

The district in the vicinity of Rhiw-Abon, particularly towards Wrexham, abounds with valuable mines. The iron ore, found in the adjacent mountains, is exceedingly rich, and affords excellent iron. The principal works carried on are those of Brymba and Bersham. The latter, which are situated at Pont-y-Penca, consist of forges, slitting, rolling, and stamping mills, &c. with an extensive cannon foundery, inferior only to that on the banks of the Carron, in North Britain. Besides cannon, these works produce wheels, cogs, bars, pipes, cylinders, rollers, columns, pistons, &c.; also furnace boilers, steam caissons, and various other articles which were formerly made of copper. Carlisle's Topographical Dictionary of Wales, 4to. 1813. A Tour round North Wales, by the Rev. W. Bingley, B.A., F.L.S., 8vo. 2 vols. 1800.

RHIZAGRA, in *Surgery*, an instrument for extracting the stumps of the teeth.

RHIZANA, in *Ancient Geography*, a town placed by Ptolemy in the interior of Dalmatia.—Also, a town of Asia, in Gedrosia, upon the sea-coast near Coiamba. Ptol.—Also, a town placed by Ptolemy in Arachosia, between Alexandria and Arbaca.

RHIZINIUM, or RHISINUM, or *Rhison*, a town of Dalmatia, on a gulf to which it gave the name of Rhisonicus Sinus. Ptol.

RHIZIUM, RHIZÉ, a town of Asia, in the Colchide, on the coast of the Euxine sea, and W. of the mouth of the small river "Rhizius."

RHIZOBOLUS, in *Botany*, a name of Gærtner's, from ῥίζα, *a root*, and βάλλω, *to throw*, or *cast*, because the plant is remarkable for throwing out a number of roots. —Schreb. 369. Mart. Mill. Dict. v. 4. Gærtn. t. 98. (Caryocar; Linn. Mant. 154. Willd. Sp. Pl. v. 2. 1243. Pekea; Aublet. Guian. v. 1. 594. Juss. 249. Lamarck Illustr. t. 486.)—Class and order, *Polyandria Tetragynia*. Nat. Ord. *Sapindi*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, fleshy, cloven half way down into five, roundish, concave segments. *Cor.* Petals five, ovate, rounded, concave, fleshy, inserted below the segments of the calyx, and much larger. *Stam.* Filaments very numerous, thread-shaped, longer than the corolla, inserted into the receptacle; anthers roundish. *Pist.* Germen superior, square, in the bottom of the calyx; styles four, thread-shaped, longer than the corolla; stigmas obtuse. *Peric.* Drupas four, kidney-shaped, compressed, inserted by their wedge-shaped inner edge into the conical receptacle, of one cell, with a fleshy covering, and a soft pulp like butter. *Seed.* Nuts solitary, kidney-shaped; kernels solitary, kidney-shaped.

Ess. Ch. Calyx five-cleft half way down. Petals five. Germen four-sided, superior. Nuts four, single-celled and single-seeded.

1. R. *butyrosus*. Lesser Suwarrow Nut. (Caryocar butyrosum; Willd. n. 1. Pekea butyrosa; Aubl. Guian. t. 238.)—Fruit smooth. Leaves digitate, smooth on both sides.—Native of woods in Guiana, and cultivated at Cayenne; where it flowers in June and July, and bears fruit in September. This lofty *tree* rises to the height of eighty feet, or more, and is much branched at the summit; the inner branches erect; the outer horizontal or declining. *Trunk* three feet in diameter, with a grey *bark*, and reddish, compact *wood*. *Leaves* opposite, digitate; leaflets entire, oval, pointed. *Flowers* white, in large bunches, at the extremities of the branches. *Fruit* yellowish.

2. R. *tuberculosus*. Large, or Common, Suwarrow Nut. (Caryocar tomentosum; Willd. n. 2. C. nuciferum; Linn. Mant. 247. Pekea tuberculosa; Aubl. Guian. t. 239.)—Fruit tubercled. Leaves digitate, downy beneath.—Native of Guiana, producing fruit in July. This *tree* differs from the preceding in having thicker *leaves* which are downy beneath, and ash-coloured. *Fruit* larger and tubercled, the pulp dry, not buttery. The *nut* is sweet and palatable, containing a rich oil. Not unfrequent in our fruiterers' shops, and known by the name of Suwarrow Nut. It is figured in Clus. Exot. 27. f. 1, by the name of Amygdala guianensis.

RHIZOMA, an appellation bestowed, by several late authors, on the tuberous *caudex*, or body, of some roots; as that of *Iris Germanica*, and many other of the natural order of *Ensatæ* of Linnæus and Gawler. See ROOT.

RHIZOMORPHA, so called from its resemblance to the branching fibrous roots of various plants, is a genus of fungi, established by Persoon, in his Synopsis, 704. One of its species, *R. subcorticalis*, figured by Micheli, Nov. Gen. t. 66. f. 3, is called by that author, p. 125, Agaricum nigrum reticulatum compressum, e mortuis arboribus inter corticem et lignum, interdum in ipso ligno innascens, ac latè se diffundens. Ray, Vaillant, and others, have likewise considered this substance as a fungus. Persoon's generic character is "Creeping, rigid, smooth, with a villous pith."

He enumerates two species besides the above; *subterranea*, found among wet timber-work, in mines; and *setiformis*, found among dead leaves in woods. This last is figured in Dill. Musc. t. 13. f. 11, b. They are all, to us, very obscure, and perhaps imperfect productions.

RHIZOPHORA, a Linnæan genus, whose name is derived from ῥίζα, *a root*, and φέρω, *to bear*, or *carry*; the seed germinating before it falls from the branches, and sending down a remarkably long cylindrical root into the earth.—Linn. Gen. 236. Schreb. 317. Willd. Sp. Pl. v. 2. 843. Mart. Mill. Dict. v. 4. Juss. 213. Lamarck Dict. v. 6. 187. Illustr. t. 396. Gærtn. t. 45. Loureir. Cochinch. 296. (Mangles; Plum. Nov. Gen. t. 15. Bruguiera; Lamarck Illustr. t. 397.)—Class and order, *Dodecandria Monogynia*. Nat. Ord. *Holeraceæ*, Linn. *Caprifolia*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, spreading, cloven into four, or more, oblong, acuminate, permanent segments. *Cor.* Petals four or more, oblong, somewhat shorter than the calyx. *Stam.* Filaments scarcely any, alternately shorter; anthers from four to twelve, small, pointed. *Pist.* Germen superior, roundish; style awl-shaped, cloven half way down, grooved at each side; stigmas acute. *Peric.* fleshy, nearly ovate, including only the base of the seed. *Seed* solitary, oblong-club-shaped, pointed, fleshy at the base.

Obs. The number in the parts of the flower varies.

Ess. Ch. Calyx four or five-cleft. Corolla of four or five petals. Seed solitary, very long, fleshy at the base.

1. R. *conjugata*. Linn. Sp. Pl. 634. Fl. Zeylan. 81. —Leaves ovate-oblong, rather obtuse, entire. Calyx sessile. Fruit cylindrical, awl-shaped.—Native of India. All that is known of this species may be gathered from the *Flora Zeylanica*, where it is described as a *tree* whose *leaves* are stalked, smooth. *Calyxes* twin. *Fruit* very long, pendent.

2. R. *gymnorhiza*. Linn. Sp. Pl. 634. (Mangium celsum; Rumph. Amboin. v. 3. 102. t. 68.)—Leaves ovato-lanceolate, entire. Root lying upon the ground.—Found in many parts of the East Indies, and in the islands of the South seas.—A middling-sized *tree* with a lofty, erect *trunk*, covered with a thick brown-red *bark*. *Leaves* on stalks, smooth, scattered, sometimes heaped together at the top. *Flowers* solitary, scattered, red, having usually from ten to thirteen petals, and twice as many stamens.

The bark of this tree is useful in dyeing a rufous or chesnut colour, which may easily be changed into a fine permanent black, as Loureiro informs us.

3. R. *Candel*. Linn. Sp. Pl. 634. (Tsjerou-Candel; Rheede Hort. Malab. v. 6. 63. t. 35.)—Leaves obtuse. Flower-stalks in forked pairs, longer than the leaf. Fruit awl-shaped. Native of the East Indies in shallow salt water. A *tree* about seven feet high. *Leaves* opposite, on short stalks, rather long, with round edges. *Flowers* composed of five or six thick, reflexed, white, slightly fragrant petals. *Fruit* very like that of the following species.

4. R. *Mangle*. Mangrove-tree. Linn. Sp. Pl. 684. Jacq. Amer. 141. t. 89. Browne Jam. 211.—Leaves pointed. Fruit slender-club-shaped. Found in moist situations, both in the East and West Indies. A *tree* about fifty feet high, with white *wood*, and a rusty-coloured *bark*. *Leaves* ovate, ribbed, entire, shining, coriaceous, dotted beneath. *Stalks* axillary, solitary, two or three-flowered, slightly triangular. *Flowers* white, having mostly eight petals.

Jacquin and Browne each give an elaborate and curious description of the fruit of this tree and the mode in which the seed germinates. From it's growing usually near the sea, the lower branches frequently become a support to the American oyster, and this circumstance doubtless gave rise to an ancient fabulous opinion, that shell-fish sometimes grew on trees, like fruit.

5. R. *cylindrica*. Linn. Sp. Pl. 635. (Cari-Candel; Rheede Hort. Malab. v. 6. 59. t. 33.)—Fruit cylindrical, obtuse.—Native of salt marshes in Malabar. This species is closely allied to *gymnorhiza*, of which indeed Gærtner considers it to be a variety. It is rather taller, and not so much branched. *Leaves* much smaller, and on shorter stalks. *Fruit* green when young, but afterwards reddish-blue.

R. *corniculata*. See ÆGICERAS.

R. *caseolaris*. See SONNERATIA.

We dare not venture to adopt *R. sexangula* of Loureiro, without further information than is furnished by that author respecting it.

RHIZUS, in *Ancient Geography*, a port of Cappadocia, near Trebizond, between the town of Pitiusa and the promontory of Athenæ. Ptolemy.

RHO, in *Geography*, a town of Italy, in the department of the Olona; eight miles W. of Milan.

RHOARA, in *Ancient Geography*, a town of Asia, in Parthia, between Casipraca and Semina. Ptolemy.

RHOAS, a river of the Colchide, according to Pliny.

RHOBASCI, a people of Scythia, on this side of the Imaus, placed by Ptolemy near the most easterly sources of the river Rha.

RHOBODUNUM, a town of Germany, upon the banks of the Danube, between Phelicia and Andupedum. Ptolemy.

RHOBOGDIUM, a promontory placed by Ptolemy in the northern part of Hibernia.

RHOBONDA, a town of Africa, in Mauritania Cæsariensis, between Tupusuptus and Ausum. Ptolemy.

RHOCAS, the watery eye. See EPIPHORA.

RHODA, or RHODE, *Rosas*, in *Ancient Geography*, a town of Hispania Anterior, belonging to the Indigetes, and N. of a small gulf. It is said to have been built by the Rhodians on the banks of a small river which flowed from the Pyrenées, and called by Pomponius Mela "Thicis." But Cellarius conjectures that it was founded by the inhabitants of Emporiæ, who came thither from the town of Rhodes, in the island of that name.—Also, a town of Gallia Narbonnensis, at the mouth and on the banks of the Rhone, according to Pliny; who adds, that it was built by the Rhodians. St. Jerome intimates that the Rhone took its name from this town.

RHODANNUS, or RODANNUS, a small river which had its source in the palatinate of Pomerania, and discharged itself into the Vistula at Dantzick.

RHODANUS FLUVIUS. See RHONE.

RHODE, a river of the European Sarmatia, in the vicinity of the Axiaces. Pliny.

RHODE *Island*, in *Geography*, one of the United States of America, situated between 41° 17′ and 42° N. lat. and between 71° 6′ and 71° 52′ W. long. Its north line is 29 miles long and its west line 49. The coast west of the bay measures 22 miles, the mouth of the bay 16, and the coast east of the bay 5, in all 43; while the greatest width measured on a parallel is 37 miles. Rhode island contains about 1580 square miles; of which about 190 are water, and about 90 are included in the islands. It is bounded N. and E. by the Massachusetts, S. by the Atlantic, and W. by Connecticut. It is divided, according to the following statement, into five counties and thirty-one townships.

Counties.	No. of Towns.	Population. 1790.	1800.	1810.	Chief Towns.
Providence	- 10	24,391	25,854	30,769	Providence.
Newport	- 7	14,300	14,845	16,294	Newport.
Washington	- 7	18,075	16,135	14,968	S. Kingston.
Kent	- 4	8,848	8,487	9,834	Warwick.
Bristol	- 3	3,211	3,801	5,072	Bristol.
Totals	- 31	68,825	69,122	76,937	

This state sends two representatives to congress. The tribe of Indians who inhabited Rhode island at the time of its settlement, was the Narragansetts, who were a brave and powerful people. The first settlement in this state was made by Roger Williams, and a party of malecontents from Massachusetts, in 1635; and in 1643 a charter was obtained for the whole colony by sir Henry Vane. The charter, on which the present constitution is founded, was obtained of Charles II. in 1663. In May 1789, Rhode island adopted the federal constitution. The inhabitants of this state are chiefly of English descent. Agreeably to the charter just mentioned, the legislature is composed of a council of 12, including the governor and deputy governor, all chosen annually, and a house of representatives, consisting of deputies from the several towns, chosen twice a-year. There is one supreme court, which sits twice a-year in each county, and an inferior court of common pleas and general sessions of the peace for each county, sitting also twice a-year. The militia of this state amount to between 7000 and 8000 men, organized and disciplined in a manner similar to the rest of the New England militia. The settlement of Rhode island is said to have originated in a religious dispute; and some of its first settlers were exiles from the Massachusetts, on account of their religious opinions. The prejudice and animosity thus excited were never thoroughly removed; but they were long cherished by the descendants of the first occupiers; and even to this day, there has never been a congregational minister settled on the west side of the

bay,

bay, except in Providence. The mass of the people, it is said, on the west side of the bay, has generally been ignorant, irreligious, and loose in their morals. The tone of religious sentiment and of morals, in Providence, Newport, and Bristol, and other towns adjoining these on the east of the bay, has been much raised by the emigrants from Massachusetts and Connecticut, and the establishment of religious institutions. The traveller sees few of the improvements in agriculture, roads, manufactures, or mode of living, which he finds in the neighbouring states; and meets with little of that civility for which other parts of New England are remarkable. The missionary labours, however, have not been without their good effects. With respect to the religious profession of this state, the Baptists are the most numerous; most of whom are Calvinistic; some are Arminians, and a few of them are seventh-day Baptists. A still smaller number consists of those who claim peculiar sanctity, and are denominated Separate Baptists. The other denominations are Congregationalists, who have eight ministers; Episcopolians, who have four, one of whom is the bishop of the eastern diocese; Moravians, and Jews. In this state religion is not supported by law; but the clergy are maintained by the voluntary contributions of their people. The number of clergy, as they have no stated salary, enforced by law, is extremely small; but the state of religion and morals, in a great part of the state, is lamentably low. Literature has of late been encouraged. Brown university at Providence, deriving its present name from Nicholas Brown, esq., who gave the institution 5000 dollars, was founded in 1764 at Warren, and removed to Providence in 1770. (See College.) Academies are established at Providence, Newport, Bristol, Warren, East-Greenwich, and South-Kingston. Schools are kept during the winter-months in most towns of the state, though not provided for by the laws; and upon the whole the state of society is improving. In this state there are 13 banks. The chief exports are flax-seed, lumber, horses, cattle, beef, pork, fish, poultry, onions, butter, cheese, barley, grain, spirits, and cotton and linen goods. More than 600 vessels enter and clear annually at the several ports. In 1804 the amount of exports was 1,735,671 dollars, and in 1810, 1,331,576 dollars. The imports consist of European and West India goods, and logwood from the bay of Honduras. The inhabitants, particularly those of Newport and Bristol, were, not long since, largely concerned in the slave trade, even in defiance of the laws of the state. A turnpike road passes from Providence, W.S.W., through Scituate and Coventry, meeting a similar road in Lisbón, Connecticut, which leads through Windham to Hartford; its length is about 25 miles. Another road strikes the Connecticut line S. of this, and passes through Norwich, New London, to New Haven and New York; this is the great southern road from Boston to New York; but the roads in this state have been much neglected. This state is reckoned as healthy as any country in America. The winters in the maritime parts of the state are milder than in the inland country; and the summers are delightful: the extreme heats that occur in other parts of America, being allayed by cool and refreshing breezes from the sea. The rivers and bays swarm with various kinds of fish; and this state produces corn, rye, barley, oats, and in some parts wheat, sufficient for home consumption, and the various sorts of grasses, fruits, and culinary roots and plants in great abundance and perfection. Cyder is made for exportation. The north-western parts of the state are rocky and barren, and of course thinly inhabited. The tract of land lying between North and South Kingston on the east, and Connecticut on the west, called "Shannock" country, or "Purchase," is excellent grazing land, and inhabited by a number of wealthy farmers, who rear some of the finest neat cattle in New England; they keep large dairies, and make butter and cheese of the best quality, and in large quantities for exportation. Iron ore is found in great plenty in several parts of the state; so that the most considerable manufactures of this state are those of iron; and also abundance of lime-stone, which furnishes lime for exportation. In this state are several mineral springs; and one in particular near Providence, to which many people resort for bathing, and for drinking the water.

Rhode *Island*, is an island from which the American state takes its name, near the coast of Massachusetts, about 40 miles S.W. from Boston. It is about 15 miles from N. to S., and on an average $3\frac{1}{2}$ miles wide, and is divided into three townships, *viz.* Newport, Portsmouth, and Middleton. This island is pleasant and salubrious, and is a noted place of resort for invalids from southern climates. Between 30,000 and 40,000 sheep are fed on the island, besides neat cattle and horses. N. lat. 41° 25′. W. long. 71° 20′.

Rhode *River*, the westernmost water of the N.W. branch of Cape Fear river, in North Carolina.

RHODEN, a town of Germany, in the county of Waldeck; 24 miles N.N.W. of Waldeck.

RHODES, *Island of*, in *Ancient* and *Modern Geography*, an island of Asia, situated in the Mediterranean, very near the coast of Caria or Natolia, and N.E. of the island of Crete, but much larger than this island. Pliny states its circuit at 125 miles; but Isidore makes it 103 miles. According to Sonnini, it is much longer than it is broad; its greatest length, in a direction from N. to S., being about 12 leagues, and breadth 6; and its circuit is commonly estimated at 44 leagues. Its form is nearly triangular, whence it obtained the name of "Trinacria;" and it was also known formerly by the names of Ophiusa, Asteria, Æthrea, Cerymbia, Poessa, Atabyria, Marcia, Oloessa, Stadia, Telchinis, Pelagia, and Rhodus. The latter appellation has prevailed in later ages; and its etymology has been sought in the Greek Rhodon, signifying a rose, with which flower the island abounded. In confirmation of this etymology it has been alleged that several Rhodian coins are still extant, exhibiting, on one side, the sun, and on the reverse a rose. Diodorus Siculus deduces the origin of its name from Rhoda, the daughter of Apollo by Venus. Others, however, have preferred the etymology of Bochart, who, availing himself of one of its ancient names, *viz.* Ophiusa or Snake island, given to it on account of the numerous snakes with which it was infested, when it was first inhabited, says that the Phœnicians also called it Snake island, which, in their language, signified "Gesirat Rhod," the latter word meaning a snake, whence the Greeks afterwards formed the name of Rhodes, which the island has since preserved. Another name by which it was distinguished, in common with the island of Cyprus, was Macaria, or fortunate, referring to the nature of the climate and of the soil. But it is said to surpass Cyprus, if not with respect to the fertility of the land, at least by its milder and more agreeable temperature. In this island the heat is not excessive, so that long droughts do not burn the plants, dry up the waters, or cause the inhabitants to suffer. The fertility and productiveness of its soil gave occasion to the fable, embellished by the poets, of those golden showers which they pretended to have once fallen upon it. It formerly produced, in great plenty, all sorts of delicious fruits, and wines of so exquisite a flavour, that they were used by the Romans chiefly in their sacrifices, and thought to be, as Virgil informs us, (Georg. l. ii.) too good for mortals. Although the heat is not scorching, yet the air is so serene, that no day ever passes without sun-shine; whence the poets feigned Phœbus

to

to be in love with this iſland, which, as they ſay, was a mere marſh, altogether uninhabitable, till it was loved by Phœbus and raiſed out of the waters by his powerful influence. To this purpoſe Sonnini deſcribes its temperate climate, pure air, and fine ſprings, which at all times ſupply the wants of its inhabitants, and render it agreeable; its vallies of a rich and fertile ſoil, covered by plentiful harveſts, and clothed with rich paſtures, ſhaded by trees bearing precious fruits, ſuch as the olive, the orange, and the fig-tree, with flowers that embelliſh with their luſtre, and perfume with their ſweet emanations; ſloping hills on which the vine is cultivated, or which preſent to numerous flocks a luxuriant and odoriferous herbage; mountains on which grow the moſt beautiful trees, whoſe verdure is perennial; all which would ſtill render it one of the moſt delightful abodes in the world, did not the iron hand of the Turks efface a part of the colours of this ſmiling picture. A gloomy nakedneſs, ſays the ſame author, diffuſes melancholy over places formerly adorned by the riches of nature and induſtry; and the men who are called thither by an agreeable and truly happy country, are driven back by the terror inſpired by a horde of ſpoilers. Happineſs no longer inhabits an iſland formerly "fortunate," and the golden ſhower, which the poets of antiquity cauſed to fall there, as an emblem of its riches and brilliant advantages, is converted into a ſtorm of deſolation.

In the time of Homer the iſland of Rhodes had three cities, *viz.* Lindus, now *Lindo*, Camirus or *Camiro*, and *Ialyſus*, the moſt ancient city in the whole iſland; to which in after ages was added a fourth, bearing the name of the iſland. (See each reſpectively.) Theſe three cities were built, according to Diodorus, by Tlepolemus, the ſon of Hercules, before the Trojan war. But Strabo and Cicero inform us, that they were founded by the Heliades, or grandſons of Phœbus, Ialyſus, Camirus, and Lindus, who gave each of them his own name. Other writers ſay, that they were built by the Dorians not long after their migration; and hence Athenæus reckons them among the Dorian colonies. Herodotus ſays, they were founded by the daughters of Danaus, who landed in this iſland, after having put to death the ſons of Ægyptus, their huſbands. In the city of Lindus was a magnificent temple, built, according to Plutarch, in honour of the Lindian Minerva, a ſtatue of which, together with the mother of Jupiter Dodonæus, both of exquiſite workmanſhip, were found in the rubbiſh of the city, after it had been accidentally reduced to aſhes, and removed to Conſtantinople. In this temple there were alſo ſeveral pictures by Parrhaſius, Zeuxis, and other great maſters. Lindus and Ialyſus were well fortified in the time of the Peloponneſian war, as we learn from Thucydides; but Camirus was without walls. The three cities now mentioned were, as Strabo informs us, three different republics, independent of each other, governed by their own laws, till the inhabitants abandoned them, and removed to the city of Rhodes.

This iſland was firſt peopled, according to Diodorus Siculus, by the Telchinæ from Crete; but dreading a deluge, they abandoned their habitations, and made way for the Heliades, or grand-children of Phœbus, who took poſſeſſion of it, after Apollo had cleared it of the mud, with which it had been covered by the deluge. The Heliades, being infeſted with ſerpents, ſent for Phorbas from Theſſaly, upon the ſuggeſtion of the oracle at Delos, who brought with him a number of Theſſalians, ſettled on the iſland, deſtroyed the ſerpents, and after his death was honoured as a demi-god. A colony of Cretans afterwards ſettled at Camirus, in this iſland, under the conduct of Althæmenes, ſon of Catreus, king of Crete; and by direction of the oracle, he was honoured after his death as a hero or demi-god. Not long before the Trojan war, Tlepolemus, the ſon of Hercules, in compliance with the inſtruction of the oracle, which he conſulted, left Argos, and ſettled in Rhodes. He here planted a colony, which he governed as king of the iſland with great equity. Diodorus ſays, theſe were the firſt inhabitants of Rhodes. After the Trojan war, the beſt part of the iſland was taken poſſeſſion of by the Dorians, who expelled the ancient proprietors, and the Doric dialect was commonly uſed throughout the whole iſland.

The Rhodians applied themſelves, at an early period, to trade and navigation, and for many ages were ſovereigns of the ſea: their laws being the ſtandard by which all controverſies relating to maritime affairs were decided. Theſe laws and conſtitutions were ſo juſt, that they were afterwards incorporated into the Roman pandects, and followed in all the provinces of the Roman empire.

The government of Rhodes was originally monarchical; and ſeveral kings are ſaid to have reigned there long before the Trojan war; but of theſe we have no account. Among the eminent writers of this iſland, we have an enumeration of the following, whoſe names we can only mention: *viz.* Ariſtophanes, Eudemus, Hieronymus, a Peripatetic philoſopher, Leonidas, Piſander, Panetius, Apollonius Molon, Timocreon, Præciphanes, Anthæas, &c. The authors of the Univerſal Hiſtory (ubi infra) have given a brief account of ſome of them, and referred for an ampler detail to Meurſius's learned treatiſe on the iſland of Rhodes, printed at Amſterdam in 1675, and publiſhed with thoſe on Crete and Cyprus by the ſame author.

In the time of the Trojan war, and after that epoch, the kings who reigned in this iſland were, Tlepolemus, Dorieus, Damagetus, Diagoras, Evagoras, Cleobulus, Eraſtides, Damagetus II., and Diagoras II. The laſt of theſe ſovereigns proved conqueror in the Olympic, Iſthmian, Nemæan, and Argian games, and on that account is celebrated by Pindar. His three ſons were alſo victors in the Olympic ſports. Upon the death of Diagoras II. ſome extraordinary revolution muſt have happened; as another family had poſſeſſion of the throne. After the death or expulſion of the laſt king, the republican government prevailed over the whole iſland; during which the Rhodians engaged in trade and navigation, became very powerful by ſea, and planted ſeveral colonies in diſtant countries; *viz.* Rhodus in Spain, and Parthenope in the country of the Opici. At this time they were maſters of the Balearic iſlands, then called the Gymnaſian iſlands. During the Peloponneſian war the Rhodians firſt joined the Athenians, revolted from them to the Lacedæmonians, and afterwards joined the former. At this time the republic of Rhodes was rent into two factions, the people favouring the Athenians, and the nobles the Lacedæmonians; but the latter at laſt prevailed; democracy was aboliſhed, and an ariſtocracy introduced in its room. Under this form of government the ſtate enjoyed a profound tranquillity, until the third year of the 105th olympiad, which was the third year of the reign of Philip the ſon of Amyntas, when the Social war broke out, which, after it had laſted five years, was concluded by a treaty, very little to the honour of Athens. By this treaty, Rhodes, Chios, Cos, and Byzantium, were to enjoy full liberty, and be quite independent of Athens. The Rhodians, however, did not remain long unmoleſted; but they were oppreſſed by Mauſolus, king of Caria, who had aſſiſted them in throwing off the Athenian yoke. After ſuffering for ſome time, they equipped a fleet, invaded Caria, and regained their liberty. Artemiſia, the queen of Mauſolus, by an act of treachery, poſſeſſed herſelf of the city of Rhodes, and put to death the chief citizens

citizens who had planned the Carian expedition. In this ſtate of diſtreſs, the Rhodians recurred to the Athenians, and either by their aſſiſtance, or by exertions on their own part, after the death of Artemiſia, were reſtored to their ancient liberty. From this time till the reign of Alexander the Great the Rhodians enjoyed undiſturbed tranquillity; and as they delivered their cities and harbours to his cuſtody, they were on that account highly favoured by that prince. Diodorus indeed tells us, that Alexander depoſited his laſt will in the archives of the city of Rhodes, and ſhewed, on all occaſions, a greater value for the Rhodians than for any other of the Greek nations. But they no ſooner had heard of his death, than, taking up arms, they drove out the Macedonian garriſons, and once more became a free people. About this time Rhodes, the capital city, ſuffered very much from an inundation, accompanied by a tempeſt and hailſtones of an extraordinary ſize, which demoliſhed many houſes, and killed a great number of the inhabitants. The Rhodians ſoon repaired the damage which they had ſuſtained, by a renewed and very ſedulous application to trade and navigation, the only ſources of their wealth and power. Although they were in amity with the neighbouring princes, and were deſirous of obſerving a ſtrict neutrality, by which prudential caution they were become one of the moſt opulent ſtates of Aſia; yet their inclination, concurring with their intereſt, they ſecretly attached themſelves to Ptolemy: the moſt advantageous branches of their commerce ſpringing from Egypt. When Antigonus, who had engaged in a war with Ptolemy for the iſland of Cyprus, demanded ſuccours of them, and they heſitated in declaring againſt their ancient friend and ally, his anger was excited, and he immediately ordered one of his admirals to ſail with his fleet to Rhodes, and ſeize all the ſhips that ſailed out of the harbour for Egypt. The Rhodians, finding their harbour blocked up by the fleet of Antigonus, equipped a great number of gallies, attacked the enemy, and obliged him, with the loſs of many ſhips, to quit his ſtation; Antigonus was incenſed, and threatened to beſiege their capital with his whole army. They remonſtrated, but with little effect, and the only terms of accommodation they could obtain, were, that they ſhould declare war againſt Ptolemy, that they ſhould admit Antigonus's fleet into their harbour, and that 100 of their chief citizens ſhould be ſurrendered as hoſtages for the performance of theſe articles. The Rhodians applied to their allies, and particularly to Ptolemy, for aſſiſtance; and after great preparations on both ſides, Demetrius put himſelf at the head of a large body of troops, increaſed by pirates and mercenaries, who wiſhed to plunder Rhodes of its riches, and having laid waſte the country round the city, approached the city itſelf with his powerful forces, and fortified his camp with ſtrong ramparts and a triple paliſade. The Rhodians adopted every poſſible meaſure for a vigorous defence. After repeated aſſaults on the part of Demetrius, which were repulſed with great ſlaughter, he brought forward a newly invented machine, called "helepolis," with a variety of other engines, and he employed in the management of them about 30,000 men. The beſieged, in the mean while, raiſed a new wall, within that which the enemy intended to batter with the helepolis. The city was furiouſly aſſaulted on all ſides, both by ſea and land; and an honourable capitulation on the part of the Rhodians being refuſed by Demetrius, the attack was renewed, and a breach made in the wall; but the beſieged fought in the breach with ſuch intrepidity, that the enemy, after ſeveral unſucceſsful attempts, were forced to abandon the enterpriſe and retire. A ſeaſonable ſupply of proviſions arriving ſafe at Rhodes, the beſieged gained new courage, and determined to ſet fire to the enemy's engines. In the execution of this project a great number of Demetrius's troops fell victims, and the conflagration was ſo great, that Demetrius thought it moſt prudent to move off his machines, leſt they ſhould be utterly deſtroyed. Whilſt the Rhodians were thus, with equal valour and perſeverance, defending themſelves and annoying the enemy, an embaſſy arrived at the camp of Demetrius from Athens, and the other cities of Greece, ſoliciting him to make peace with the Rhodians. A ceſſation of arms was agreed upon, and terms were offered by Demetrius, which were rejected by the Rhodians. The aſſault was renewed, and a breach having been made, it was entered by a detachment of Demetrius's men; which occaſioned great confuſion in the city: but the Rhodians fought like men in the utmoſt deſpair, and animated by their leaders, who encouraged one another, they propoſed a laſt effort for the defence of their city and country, which was that of breaking into the very centre of the enemy's battalion, in the execution of which meaſure they killed both their commanders. After their death, the reſt were eaſily thrown into diſorder, and all to a man were either killed, or taken priſoners. The Rhodians alſo, on this occaſion, loſt many of their braveſt commanders. At length the helepolis was rendered uſeleſs, by the ſtratagem of a Rhodian engineer, and this misfortune, it is ſaid, induced Demetrius to conclude a peace. Thus the ſiege, after it had continued a whole year, was raiſed (B.C. 303); and the Rhodians amply rewarded all thoſe who had diſtinguiſhed themſelves in the defence of their country. One inſtance of laudable conduct on the part of Demetrius during the ſiege deſerves to be recorded. At this time Protogenes, a celebrated painter, who was a native of Cannus, a city of Caria, reſided at Rhodes. His houſe was in the ſuburbs; and he could not be prevailed upon to quit it. The prince, ſurpriſed at this reſolution, aſked him why he did not, like the other inhabitants, ſecure himſelf within the walls? Protogenes replied, that he was under no apprehenſion, ſince he was ſenſible that Demetrius had declared war againſt the Rhodians, and not againſt the arts. The prince was ſo pleaſed, that he took the painter under his protection, and placed a guard round his houſe, to preſerve him from the inſults of the ſoldiery. The chef-d'œuvre of this Protogenes was the picture of Ialyſus, ſuppoſed by the Rhodians to have founded their city. The Rhodians having concluded a peace upon advantageous and honourable terms, devoted themſelves again to trade and navigation; by which they not only became maſters of the ſea, but the moſt opulent and flouriſhing ſtate of all Greece. Their next war was with the Byzantines; and about the time of its termination the famous Coloſſus of Rhodes was overturned by an earthquake, which did other conſiderable damage. In the year B.C. 203, the Rhodians joined Attalus, king of Pergamus, againſt Philip, king of Macedon; and a triple alliance was formed between the Romans, Attalus, and the Rhodians. In proceſs of time, the fidelity of the attachment of the Rhodians to the Romans, of which they had once and again exhibited unequivocal evidence, was ſuſpected; and this ſuſpicion was confirmed when they engaged with Perſes, the ſon of Philip, to ſtand neuter. The Roman ſenate was incenſed, and the Rhodians ſent meſſengers to appeaſe their wrath, but their efforts were unavailing. At length, however, in the year B C. 166, they were admitted to an alliance with Rome and favoured by the ſenate. From this period, to the breaking out of the Mithridatic war, the Rhodians enjoyed their liberties, while all the other ſtates and colonies of Greece were brought under the Roman yoke, and became provinces of that republic. In the civil war between Cæſar and Pompey, they aſſiſted the latter with a numerous fleet; but after the death of Pompey they

they ſided with Cæſar, which drew upon them the diſpleaſure of C. Caſſius, who advanced to their iſland with a powerful fleet, and demanded the ſurrender of their fleet, with which demand they refuſed to comply. The conſequence was a ſea-engagement, in which the Rhodians were defeated; and it has been obſerved, that this was the firſt time in which they were fairly overcome in a ſea-fight. Caſſius proceeded to take poſſeſſion of Rhodes and to plunder it. He alſo ordered fifty of the chief citizens to be put to death, and others were proſcribed. He ſtripped them of all their money, and even the temples of all their valuable furniture, veſſels and ſtatues. He announced, by a public cryer, that any perſon who ſhould diſcover any hidden treaſures ſhould receive a tenth part by way of recompence; and the reſult was, that he thus extorted from private perſons above 8000 talents. He then fined the city in 500 more, and leaving L. Varus, with a ſtrong garriſon to exact the fine, without any abatement, he returned to the continent.

After the death of Caſſius, Marc Antony reſtored the Rhodians to their ancient rights and privileges, beſtowing upon them the iſlands of Andros, Naxos, Tenos, and the city of Myndus. But theſe the Rhodians ſo oppreſſed and loaded with taxes, that Antony, though a great friend to the Rhodian republic, was obliged to diveſt her of the ſovereignty over thoſe places, which he had, a little before, ſo liberally beſtowed upon her. From this time to the reign of the emperor Claudius, we find no mention made of the Rhodians. That prince deprived them of their liberty for having crucified ſome Roman citizens. However, he ſoon reſtored them to their former condition, as we read in Suetonius and Tacitus. The latter adds, that they had been as often deprived of, as reſtored to, their liberty, by way of puniſhment or reward for their different behaviour, as they had obliged the Romans with their aſſiſtance in foreign wars, or provoked them with their ſeditions at home. Pliny, who wrote in the beginning of Veſpaſian's reign, ſtyles Rhodes a beautiful and free town. But this liberty they did not long enjoy, the iſland being ſoon after reduced, by the ſame Veſpaſian, to a Roman province, and obliged to pay a yearly tribute to their new maſters. This province was called the province of the iſlands. The Roman prætor, who governed it, reſided at Rhodes, as the chief city under his juriſdiction; and Rome, notwithſtanding the eminent ſervices rendered her by this republic, thenceforth treated the Rhodians not as allies but vaſſals.

Under Conſtantine this iſland remained part of the Eaſtern empire; but the puſillanimity and vices of the princes who ſucceeded, ſhook it to its foundation. In the twelfth year of the reign of Conſtans, Moawiah, Othman's lieutenant, made himſelf maſter of Rhodes. At length the Greek emperors expelled the Mahometans, and kept poſſeſſion till the time of Baldwin, who, having made himſelf ſovereign of Conſtantinople, ſent a prefect to Rhodes. Some time after it was conquered by Ducas. Then the brave warriors, known by the name of the knights of St. John, attacked, and, after a bloody battle, took it; in which heroiſm triumphed over numbers and valour. Mahomet II. tarniſhed the luſtre of his laurels, by beſieging this place, defended by a ſmall band of heroes. In the year 1523, Soliman ſaw a numerous army periſhing under its walls; and if this redoubtable conqueror of Hungary and Perſia did at length ſubdue Rhodes, attacked on all ſides by the forces of the Turks, the greater was the ſhame of the Chriſtian princes, who did not ſend a ſingle veſſel to the aid of its intrepid defenders. Deſtroyed, rather than vanquiſhed, they were almoſt buried under the ruin of their forts. Soliman could not enter the town without wading through the blood of his ſoldiers; and in it he found nothing but heaps of ruins, defended by a ſmall company of knights, covered with wounds, who afterwards removed to Malta. (See MALTA). The governor-general of this iſland is a pacha, who has abſolute power. The Greeks and Jews have a chief, named the Moutevali, who is their intendant-general, and has the regulation of the tax, called carach,—a capitation tax impoſed by the grand ſeignior on all his ſubjects who are not Mahometans, but is paid only by the men.

The ſoil of the iſland is dry and ſandy, but watered by its numerous ſprings. It is very fertile: corn thrives well; and its yellow and heavy grain affords flour as white as ſnow, which makes excellent bread. It needs only cultivation to raiſe an ample ſupply, not only for its own conſumption, but for a large exportation. The number of families in the whole iſland is eſtimated at 4700 Turks, 2500 Greeks, and 100 Jews, in all 7300, or about 36,000 inhabitants. N. lat. 36° 26'. E. long. 27° 32'.

RHODES, the capital city of the iſland above deſcribed, as well as the chief ſeat of its government, is ſituated to the N.E. of the iſland, at the foot of a hill of gentle aſcent, and in an agreeable plain, environed at ſome diſtance with ſeveral hills full of ſprings, and covered with all kinds of fruit-trees. This ſtately city was built by the ſame architect whom the Athenians had employed in building the Piræus, or part of Athens; *viz.* Hippodamus, a native of Miletus, and eſteemed one of the beſt architects Greece ever produced. It was built, according to Strabo and Ariſtides, in the form of an amphitheatre, ſurrounded with walls like thoſe of Munichia, embelliſhed with moſt ſtately buildings, ſtraight and broad ſtreets, pleaſant avenues, fine groves, large ſquares, &c. Dio Chryſoſtom ſays, that moſt of the Pagan deities had temples in this city; among which that of the Sun, called by the Dorians Halcium, was one of the moſt noble ſtructures of antiquity. Strabo mentions the temple of Bacchus, enriched with a great number of pictures by Protogenes. Heſychius, Appian, and Suetonius, ſpeak of the temples of Iſis, of Ocridian, and Diana, as maſter-pieces of art. Each of theſe temples contained immenſe treaſures, the offerings of votaries from all parts of Greece, Aſia, and Italy. In the Dionyſium, or temple of Bacchus, was a ſtatue of Pluto of maſſy gold, and an incredible number of other ſtatues and pictures. Pliny informs us, that, in his time, there were in the city of Rhodes above 3000 ſtatues, moſt of them executed with great taſte; and Ariſtides ſays, that there were more valuable ſtatues and pictures in this ſingle city than in all the other cities of Greece. The pictures of Menander, king of Caria, and of Anæus, the ſon of Neptune, by Apelles, and thoſe of Perſeus, Hercules, and Meleager, by Xeuxis, are highly extolled by Pliny, and other ancient writers. That of Meleager was there ſcorched by lightning, as Pliny tells us, but that accident did not in the leaſt deaden the luſtre and brightneſs of its colour.

In the Roman times this city was famous for the ſtudy of all ſciences, and reſorted to by ſuch of the Romans as were deſirous of improving themſelves in literature; ſome of the ancients repreſenting it as equal to Athens itſelf. It had a very convenient harbour, at the entrance of which were two rocks; and on theſe rocks, though 50 feet aſunder, the famous coloſſus is ſuppoſed to have ſtood. See COLOSSUS.

The city of Rhodes is ſtill a place of conſiderable note; being pleaſantly ſituated on the ſide of a hill, three miles in compaſs, and fortified with a treble wall; but its ramparts partake of the ſame neglect and decay of every thing that is in the poſſeſſion of the Turks. The ſtreets are wide, ſtraight, and well paved; and the houſes built after the Italian taſte. The chief haven is now very different from what it is ſaid to have been in its ancient ſtate. It is no

longer

longer that basin, whose deep waters afforded a commodious shelter to ships of every size; nor are the quays enlivened by the activity of a flourishing trade. It is now little frequented except by Greek boats, and by a few merchant vessels which put in there; it is half choked up, and ships of war are obliged to cast anchor without, where they are but indifferently protected from the winds and waves by some points of land and some shoals. The entrance of the harbour is defended, on the one side, by a square tower, constructed by a grand master of the order; inscriptions and other marks recall to mind the period of its foundation. The Turks still call it St. John's tower, although the Greeks have changed this name into that of St. Nicholas, more generally adopted in the Levant. On the other side is a tower, not so high, nor so strong, which is named St. Angelo's or St. Michael's tower. The harbour is as if divided into two by a small mole, which projects within it, and forms an inclosure, into which boats alone can enter, and which, on that account, is called Boat harbour. Independently of the large harbour, there was another on each side; the one was the harbour for gallies, where they can no longer enter at this day; the other is choked up, and almost entirely dry. Every thing, says Sonnini, is destroyed; every thing is annihilated under a government, which knows only to enjoy, or rather to abuse the present, and to which the most simple calculations of foresight are unknown. Yards for shipbuilding, which might, with so much reason, be called workshops of dilapidation, are established at Rhodes for the Ottoman navy; the timber is brought from the fine and vast forests of Caramania, and even from those of the island. But the construction of ships is so slow, and the timber so injudiciously selected, that they are sometimes half-rotten before they are entirely finished.

In several places of the city of Rhodes are still to be seen marks of the ancient possession of the order of St. John of Jerusalem; a long street preserves the name of Rue des Chevaliers; it is perfectly straight, and formed of old houses, in which remain the armorial bearings of the members of the order. The ancient church of St. John is become the principal mosque; the hospital has been transformed into public granaries; and the palace of the grand master, falling into ruins, is almost entirely deserted. N. lat. 36° 25′. E. long. 27° 45′.

Rhodes, a town of Africa, in the kingdom of Tunis, situated on an eminence, between the lake of Tunis and the sea, at a distance from some hills, where Hanno was defeated by Regulus.

RHODIA, in *Botany.* See Rhodiola.

RHODIGINUS, Cœlius, in *Biography*, a learned Italian, whose proper name was Ludovico Celio Richeri, was born at Rovigo about the year 1450. He studied at Ferrara and Padua, and then travelled into France, in which country he resided a considerable time. On returning to Italy, he filled the office of public professor in his native place from 1491 to 1497, and again obtained the same appointment in 1503; after this he opened a school at Vicenza, where he continued till 1508, when he was invited to Ferrara by duke Alfonzo I. In the year 1515, Francis I. nominated him to the chair of Greek and Latin eloquence in Milan, as successor to Demetrius Chalcondylas. He returned in 1521 to Padua, and in 1523 he was re-admitted to the council of his native city, and deputed from it to Venice, to congratulate the new doge. So great was his loyalty, or his gratitude, that, in 1525, he died of grief, on account of the defeat and capture of Francis at the battle of Pavia. He was author of various works; of these, the principal is entitled "Antiquæ Lectiones," of which he published sixteen books, and fourteen more were added after his death. It was printed at Basil in 1566, and again at Franckfort in 1666. It has been characterised as a miscellany of profound erudition, in which abstruse words in Greek and Latin are explained, obscure passages in the best authors are elucidated, and corrupt ones rectified; recondite histories and ancient rites are narrated, and many arcana of the deepest philosophy, especially of the Platonic school, are brought to light; "whence," says the learned Vossius, "I am often moved with wonder, and indeed with indignation, in observing that the precious labours of such a man are so little in the hands of the youth of the present time." By Julius Scaliger he was denominated "the Varro of the age." Gen. Biog.

RHODIOLA, in *Botany*, from ῥόδον, *a rose*, because the root of this plant, when dried, has a rose-like smell. Rhodiola is literally the diminutive of Rhodia, a name applied by ancient writers to the wood or root of some plant (suspected by Linnæus to be a *Convolvulus*) possessing a similar fragrant property.—Rose-Root.—Linn. Gen. 526. Schreb. 693. Willd. Sp. Pl. v. 4. 807. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 1082. Ait. Hort. Kew. v. 5. 397. Juss. 307. Lamarck Illustr. t. 819.—Class and order, *Dioecia Octandria.* Nat. Ord. *Succulentæ*, Linn. *Sempervivæ*, Juss.

Gen. Ch. Male, *Cal.* Perianth inferior, four-cleft, concave, erect, obtuse, permanent. *Cor.* Petals four, oblong, obtuse, erect, spreading, twice as long as the calyx, deciduous. Nectaries four, erect, emarginate, shorter than the calyx. *Stam.* Filaments eight, awl-shaped, longer than the corolla; anthers simple. *Pist.* Germens four, superior, oblong, acuminate; styles and stigmas obsolete. *Peric.* abortive. *Seeds* none.

Female, *Cal.* Perianth as in the male. *Cor.* Petals four, generally imperfect, of a coarse texture, erect, obtuse, equal with the calyx, permanent. Nectaries as in the male. *Pist.* Germens four, superior, oblong, acuminate, ending in simple, straight styles; stigmas obtuse. *Peric.* Capsules four, corniculate, opening inwardly. *Seeds* numerous, roundish.

Obs. Schreber says (in his Appendix, 839), that professor Dahl having seen specimens of Rhodiola with perfect flowers, *viz.* with ten stamens and five pistils, the genus should properly be united to Sedum. Linnæus, however, in his *Flora Lapponica*, mentions a specimen found in Lapland with perfect flowers; but, at the same time, he tells us, that such flowers are barren, none being fertile, except those true female flowers, on a separate plant, which have no stamens, and but imperfect petals. Hence it appears, that the present plant is truly dioecious in habit, although it may occasionally incline to the perfect structure of Sedum.

Eff. Ch. Male, Calyx in four parts. Petals four. Nectaries four, notched.—Female, Calyx and nectaries like the male, but somewhat smaller. Petals of a coarse texture. Capsules four, many-seeded.

1. R. *rosea.* Rose-root. Linn. Sp. Pl. 1465. Engl. Bot. t. 508. Fl. Dan. t. 183.—Found in the clefts of Alpine rocks, and sometimes on rocks by the sea-shore, in different parts of Great Britain; flowering in May and June. —*Root* perennial, fleshy, white or greyish, when dried emitting a fragrance like that of rose-water. *Stems* perfectly simple, erect, a span high, thickly beset with leaves. *Leaves* imbricated, sessile, obovate, acute, fleshy, glaucous, smooth, toothed towards the top, in the male tipped with red. *Cyme* terminal, sessile, much branched, composed of numerous yellow flowers, the female ones dotted with red.

—It ſhould be remarked, that the odour of the root is greatly impaired by culture.

Miller cultivated a variety of this plant for many years at Chelſea, which was ſmaller in all its parts, and had purpliſh flowers.

We can by no means admit *Rhodiola biternata*, Loureir. Cochinch. 627, becauſe that author had never ſeen the female flowers; and his deſcription of its twining ſtem, and doubly-compound leaves, renders it in habit ſo totally unlike the original *Rhodiola*.

Rhodiola, in *Gardening*, comprifes a plant of the low herbaceous, odoriferous, ſucculent, perennial kind, of which the ſpecies cultivated is the common, or yellow roſewort (R. roſea).

Of which there is a variety, in which the roots are ſmaller; the ſtalks ſmall, and not above five inches long; the leaves ſmall, ending with a purple point; the petals are purpliſh, and the ſtamens little longer than the petals. It flowers later than the common ſort.

Method of Culture.—This plant may be increaſed by planting cuttings of the ſtalks in the beginning of April, ſoon after they come out from the head, in a ſhady border; covering them cloſe down with a glaſs, and keeping them dry, when they moſtly put out roots in about ſix weeks; but the cuttings ſhould be laid in a dry room at leaſt a week before they are planted out, otherwiſe they are apt to rot and be deſtroyed. They may alſo be raiſed by parting the roots in the beginning of autumn, when the ſtalks begin to decay; and when the fleſhy parts are cut or broken, they ſhould be laid to dry a few days before they are planted. They require a ſhady ſituation, and a dry undunged ſoil, in which they will continue many years. They afford variety in the borders, clumps, &c.

RHODITES Lapis, the *Roſe-ſtone*, in *Natural Hiſtory*, the name given by authors to a kind of aſtroites, or ſtar-ſtone, in which the figures more repreſent roſes than ſtars; they are in both owing to coralloide bodies immerſed in the ſtone; which, according to their various ſpecies, afford a different figure, when cut tranſverſely, in cutting the ſtone into plates for uſe.

RHODIUM, in *Chemiſtry*, a new metal, found in crude platina, ſo called from the roſe-colour of a dilute ſolution of the ſalts containing it, by Dr. Wollaſton, to whoſe inquiries we are indebted for proof of its exiſtence, and an account of its properties. This metal is thus procured: ſome crude platina being digeſted in moderately dilute nitro-muriatic acid, a browniſh-red ſolution is obtained; from this the platina is to be ſeparated, for the moſt part, by muriate of ammonia, and the reſidual liquor is to be heated with zinc; by this treatment a black powder will be obtained, and the ſupernatant fluid will conſiſt of the muriates of zinc and iron. This black powder, by digeſtion in very dilute nitric acid, will be freed from the copper and lead which it uſually contains, and the reſidue is to be digeſted in dilute nitro-muriatic acid, till every thing ſoluble is taken up. To this ſolution a little common ſalt is to be added, and the whole evaporated to dryneſs; after which, by repeatedly waſhing with warm alcohol, the ſoda-muriates of platina and palladium will be diſſolved, leaving behind a pure ſoda-muriate of rhodium.

This ſalt is readily ſoluble in hot water, and depoſits on cooling rhomboidal cryſtals of a bright roſe-colour. Sal ammoniac occaſions no turbidneſs in the ſolution; but if a few drops of muriate of platina are added to the mixture, an immediate yellow precipitate is thrown down. Neither pruſſiat of potaſh, nor hydro-ſulphuret of ammonia, nor the carbonated alkalies, produce any precipitate; but the pure alkalies throw down a yellow oxyd, ſoluble either in alkalies or acids. The muriate of this metal is an uncryſtallizable ſalt of a roſe-colour, and ſoluble in alcohol; with nitre, or the muriates of ammonia or ſoda, are formed cryſtallizable triple ſalts inſoluble in alcohol.

Nitrate of rhodium is alſo uncryſtallizable. It appears not to be decompoſable by ſilver, but is ſo by copper, mercury, and moſt of the other metals.

The ſoda-muriate of this metal affords a black powder by digeſtion with zinc; which, when heated with borax, acquires a white metallic luſtre, but is infuſible by any heat that has hitherto been applied. It is, however, fuſible, either with arſenic or ſulphur, and may be again ſeparated from thoſe ſubſtances by heat, but it does not acquire by this treatment any degree of malleability. It combines with moſt metals, and with ſilver and gold forms very malleable alloys, which are unaltered by a high heat, but become encruſted with a black oxyd when ſlowly cooled; an alloy of ſix parts of gold and one of rhodium differs but little in colour from fine gold, but is much more difficultly fuſible. The ſpecific gravity of rhodium appears to be ſomewhat more than 11. That of an alloy conſiſting of one part rhodium and about two parts lead, was 11.3; which is ſo nearly that of lead itſelf, that each part of this compound may be conſidered as having about the ſame ſpecific gravity. Phil. Tranſ. for 1804, vol. xciv. pt. 2. See Palladium and Platina.

Rhodium *Lignum*. See Aspalath.

Rhodium *Marmor*, a name given by the ancients to a marble brought from Rhodes; it was a good white, but inferior to the Parian, and was uſed by the Romans in their public buildings, and ſometimes in ſtatuary.

RHODIUS, in *Geography*, a river of European Turkey, which takes its ſource N.E. of mount Ida; and after receiving ſome rivulets which flow from the neighbouring mountains, and traverſing a ſpace of twelve or fifteen miles, diſcharges itſelf into the Helleſpont, by the ſide of the caſtle of Dardanelles. Its waters, which are far from being abundant in ſummer, are kept back and employed in the irrigation of the lands; but in winter, ſwelled by the rains which are frequent in that ſeaſon, it occupies a bed ſufficiently large to deſerve the name of river. The inhabitants of the Dardanelles, built on its banks, have conſtructed a wooden bridge, at ſome diſtance from its mouth, in order to be able to croſs at all times to the left bank, and repair to the fields which they cultivate beyond it. Behind the caſtle, between the town and the river, is a tolerably extenſive walk, naturally turfed, and ſhaded by very tall plane-trees. This river waters an extremely fertile valley, formed by a plain to the eaſt of the town. In this town are reckoned ſcarcely 4000 inhabitants, Greeks, Muſſulmans, and Jews. Its poſition is agreeable, its territory is fertile, and its productions are very diverſified. To the N.E. is a riſing ground, covered with vines; and at the extremity of the fore-mentioned valley are found indications of a volcano; among others are to be ſeen conſiderable blocks of granite, the quartzoſe part of which is almoſt converted into glaſs. A little farther on is a fertile and circular bottom of ſmall extent, ſurrounded by mountains covered with wood.

In the territory of the Dardanelles are cultivated cotton, ſeſamum, various kitchen-garden plants, the vine, the olive-tree, and ſeveral ſpecies of fruit-trees. The orange-trees begin to grow here in the open air; and a tolerable large quantity of grain is collected here. The neighbouring mountain furniſh the "velanida," (ſee Quercus *Ægilops*,) and gall-nut uſed in trade. Olivier.

Rhodius, in *Ichthyology*, the Acipenser *Sturio*. See Sturgeon.

RHODODENDRA, in *Botany*, a natural order of plants, named after its principal genus, (ſee the next article,) and

and conſtituting the fiftieth in Juſſieu's ſeries, or the ſecond of his ninth claſs; for the characters of which claſs ſee ERICÆ and GUAIACANÆ. The following are the marks of the order in queſtion.

Calyx divided, permanent. *Corolla* inſerted into the bottom of the calyx; ſometimes of one petal, and lobed; ſometimes almoſt polypetalous, the limb being ſo very deeply divided. *Stamens* definite, diſtinct; in the monopetalous genera inſerted into the corolla; in the reſt into the baſe of the calyx. *Germen* ſuperior; ſtyle one; ſtigma ſimple, often capitate. *Capſule* ſuperior, of ſeveral cells, and ſeveral valves, both margins of each valve inflexed, and connected with the central axis, (or *columella*,) ſo that each forms a cell, containing numerous minute ſeeds. *Stem* ſhrubby, more or leſs lofty. *Leaves* alternate, or more rarely oppoſite; the young ones, in many inſtances, revolute at the margin.

Section 1. *Corolla monopetalous.*

Kalmia, Rhododendrum, and *Azalea*; all Linnæan genera; to which is to be added MENZIESIA; ſee that article.

Sect. 2. *Corolla imperfectly polypetalous.*

Rhodora, Ledum, Befaria, (now more correctly written *Bejaria*, by Ventenat and others; the Spaniards having pointed out the error, which originated in a miſtake of Linnæus, in reading Mutis's manuſcript,) and *Itea*; all likewiſe Linnæan genera.

Juſſieu conſiders the *Rhododendra* as eſſentially diſtinguiſhed from his *Ericæ*, by the want of horns to the anthers, and eſpecially by the inflexed margins of the valves of the capſule. It does not appear to us that theſe characters are, either of them, ſtrictly abſolute. Mr. Saliſbury has long ago obſerved, that the leaves of the *Rhododendra* have always a remarkable glandular tip.

RHODODENDRUM, from ῥόδον, *a roſe*, and δένδρον, *a tree*, a name adopted by Linnæus from Dioſcorides, whoſe ῥοδόδενδρον however is but a ſynonym to his νήριον, our *Nerium*, or Roſe-bay; the ῥοδοδάφνη of the modern Greeks.—Linn. Gen. 218. Schreb. 294. Willd. Sp. Pl. v. 2. 603. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 3. 49. Purſh v. 1. 297. Juſſ. 158. Lamarck Illuſtr. t. 364. Gærtn. t. 63. —Claſs and order, *Decandria Monogynia*. Nat. Ord. *Bicornes*, Linn. *Rhododendra*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, in five deep ſegments, permanent. *Cor.* of one petal, widely funnel-ſhaped; its limb ſpreading, with five rounded unequal ſegments. *Stam.* Filaments ten, thread-ſhaped, about the length of the corolla, declining; anthers incumbent, oval, abrupt, of two cells, opening by two terminal pores. *Piſt.* Germen with five angles, abrupt; ſtyle thread-ſhaped, the length of the corolla; ſtigma obtuſe. *Peric.* Capſule ovate, ſomewhat angular, of five or ten cells, formed by the inflexed margins of the valves, which finally ſeparate from the five or ten-angled central column. *Seeds* numerous, minute.

Eſſ. Ch. Calyx inferior, in five diviſions. Corolla of one petal, ſomewhat funnel-ſhaped, irregular. Stamens declining. Capſule of five or ten cells; partitions from the inflexed margins of the valves.

1. R. *ferrugineum*. Ruſty-leaved Rhododendrum. Linn. Sp. Pl. 562. Willd. n. 1. Ait. n. 1. Jacq. Obſ. faſc. 1. 26. t. 16. Auſtr. t. 255.—Leaves ſmooth; ruſty beneath. Cluſters terminal. Corolla with a cylindrical leprous tube. Calyx fringed.—Native of heathy plains on the alps of Switzerland, Savoy, Auſtria, Siberia, and the Pyrenees, flowering in Auguſt. It is not difficult of culture with us, in bog earth, on an open border, and is one of the moſt elegant of ſhrubs. The *ſtem* is about two feet high, very buſhy. *Leaves* evergreen, ſtalked, alternate, elliptic-oblong, an inch or an inch and a half in length; convex, ſmooth, and dark ſhining green above; ruſty beneath, but deſtitute of all pubeſcence. *Flowers* above half an inch long, in terminal roundiſh cluſters; their *corolla* of a peculiarly rich and beautiful crimſon, externally dotted with white. Haller ſays there is a rare white-flowered variety. The plain of mount Cenis glows with the rich bloſſoms of this plant in July and Auguſt, exhibiting one of the moſt lovely ſcenes in nature. See Smith's Tour on the Continent.

2. R. *hirſutum*. Hairy Rhododendrum. Linn. Sp. Pl. 562. Willd. n. 4. Ait. n. 3. Jacq. Auſtr. t. 98. (Ledum alpinum; Cluſ. Hiſt. v. 1. 82. Ger. Em. 1290. Balſamum alpinum Geſneri; Lob. Ic. 367.)—Leaves elliptic-obovate, ſharpiſh, fringed; dotted beneath. Corolla with a cylindrical leprous tube.—Native of the Swiſs and Auſtrian alps. Cultivated, like the former, in this country; flowering rather earlier. This is moſt nearly related to *R. ferrugineum*, next to which therefore we prefer placing it. The chief diſtinction conſiſts in the *leaves* being fringed with rigid hairs; their form more obovate and flat, and their under ſide leſs ruſty. We never could perceive much difference in the *flowers*, except perhaps thoſe of *hirſutum* being rather paler, and more of a pink hue.

3. R. *dauricum*. Daurian Rhododendrum. Linn. Sp. Pl. 562. Willd. n. 2. Ait. n. 2. Pall. Roſſ. v. 1. t. 32. Curt. Mag. t. 636. Andr. Repoſ. t. 4. (Chamærhododendros folio glabro majuſculo, amplo flore roſeo; Amm. Ruth. 181. t. 27.)—Leaves elliptic-oblong, dotted, naked. Corolla nearly wheel-ſhaped.—Native of Siberia, in mountainous ſituations. It ſucceeds in our gardens with the ſame treatment as the two foregoing, but flowers much earlier, and though evergreen in its own country, is leſs perfectly ſo with us; requiring moreover ſome ſhelter for its bloſſoms, during the ſeverity or uncertainty of our winter or early ſpring. The *leaves* are dotted on both ſides with minute ſcales, and their midrib is, when young, a little downy. *Flowers* roſe-coloured, nearly ſeſſile; their corolla widely expanded, with ſcarcely any tube, its outſide ſlightly hairy, not leprous. Mr. Andrews ſeems to have printed "*petiolis longiſſimis*," by miſtake for "*breviſſimis*," as the *footſtalks* are in fact very ſhort.

4. R. *camtſchaticum*. Barberry-leaved Rhododendrum. Pall. Roſſ. v. 1. p. 1. 48. t. 33. Willd. n. 3. (Chamærhododendros berberis folio, flore amplo roſeo; Gmel. Sib. v. 4. 126.)—Leaves obovate, fringed, ſmooth, reticulated with veins. Corolla wheel-ſhaped. Found by Steller, in mountainous ſpots in Beering's iſland, and the north-eaſt part of Kamtſchatka, flowering in July and Auguſt. The ſhrubby *ſtems* are procumbent, branched, about a foot long. *Leaves* ſtalked, obovate, an inch or more in length, blunt, with a very ſmall point, fringed at the margin, but ſmooth on both ſides, deſtitute of dots or ſcales, of a thin texture, ſtrongly and copiouſly reticulated with interbranching ribs and veins. *Flowers* roſe-coloured, larger than the laſt, being nearly two inches wide, each on a long, ſolitary, hairy, terminal ſtalk. *Segments* of the calyx flat, oblong, obtuſe, ribbed and veiny, ſometimes very hairy externally, ſometimes only fringed at the edges. This very ſhowy plant is mentioned in Mr. Aiton's Epitome of Hort. Kew. 373, as having come into the hands of our cultivators in 1799, but we have never met with it in any garden.

5. R. *Chamæciſtus*. Thyme-leaved Rhododendrum. Linn. Sp. Pl. 562. Willd. n. 5. Ait. n. 4. Jacq. Auſtr. t. 217. Curt. Mag. t. 488. (Ledum foliis ſerpilli, ad margines cilii inſtar piloſis, flore purpureo; Mich. Gen. 225. t. 106. Ciſtus humilis auſtriaca Cluſii; Ger. Em. 1278.)—Leaves obovate, acute, fringed, poliſhed, almoſt veinleſs. Corolla wheel-

wheel-ſhaped.—Native of the alps of Auſtria, Carniola, and the north of Italy. Firſt raiſed from ſeed in England, in 1786, by the ſkilful Mr. Loddiges of Hackney. A ſhrubby nearly procumbent plant, much ſmaller than the laſt, and differing eſſentially in the more thick and coriaceous texture of its *leaves*, which are of a dark green, and highly poliſhed, with ſcarcely any viſible veins. The elegant purpliſh *flowers* are not above an inch broad. Their *calyx* has hairy, convex, not flat, ſegments. Anthers deep purple.

6. R. *caucaſeum*. Caucaſian Rhododendrum. Pall. Roſſ. v. 1. p. 1. 46. t. 31. Willd. n. 6. Ait. n. 5. Curt. Mag. t. 1145.—Stem decumbent. Leaves rugged above; downy and ruſty beneath. Umbels terminal. Corolla nearly wheel-ſhaped.—Native of the loftieſt ſummits of mount Caucaſus, near perpetual ſnow, where, according to Pallas, nothing elſe, beſides Whortle-berries and Juniper, grow. Introduced at Kew, by ſir Joſeph Banks, in 1803. Mr. Loddiges finds it flower more freely under his care than the following. A low ſhrub, ſpreading on the ground, but of a ſtouter habit, with larger more coriaceous foliage, than any of the foregoing. The *leaves* are elliptical, ſtalked, three or four inches long; convex and of a dark ſhining green, with a rugoſe ſurface, above; concave, veiny, and covered with fine ruſty down, underneath. *Footſtalks* alſo downy. *Flowers* large, moderately concave; white or pale fleſh-coloured within, their upper ſegments dotted about the baſe with green; the outſide crimſon. They form terminal *umbels*, with large, oblong, concave, permanent *bracteas* at the baſe.

7. R. *chryſanthum*. Yellow Rhododendrum. Linn. Suppl. 237. Willd. n. 7. Ait. n. 6. Pall. Roſſ. v. 1. p. 1. 44. t. 30. (R. officinale; Saliſ. Parad. t. 80. Andromeda, n. 9; Gmel. Sib. v. 4. 121. t. 54.)—Stem decumbent. Leaves reticulated, ſmooth on both ſides; paler beneath. Umbels terminal. Corolla nearly wheel-ſhaped. Native of the mountains of Siberia, Kamtſchatka, and Beering's iſland. Introduced by Mr. Joſeph Buſh, in 1796, into our gardens, where it flowers, though rarely in the middle of ſummer, like the laſt. Some have imagined theſe two ſpecies to be varieties of each other; but the preſent differs eſſentially in having the *leaves* quite ſmooth and naked beneath, not to mention the uniformly yellow colour of the *flowers*. An infuſion of the young leaves is much celebrated in Ruſſia as a cure for the rheumatiſm. This medicine is taken internally, to promote perſpiration. Some have recommended it for venereal complaints. Willdenow juſtly obſerves, that this ſhrub is altogether different from *R. dauricum*, to which the younger Linnæus, by ſome ſtrange miſtake, compares it.

8. R. *ponticum*. Purple Rhododendrum. Linn. Sp. Pl. 562. Willd. n. 8. Ait. n. 7. Jacq. Ic. Rar. t. 78. Pall. Roſſ. v. 1. p. 1. 43. t. 29. Curt. Mag. t. 650. Andr. Repoſ. t. 379. (Chamærhododendros pontica maxima, folio laurocerasi, flore cæruleo-purpuraſcente; Tourn. Voyage, v. 2. 99.)—Leaves oblong, ſmooth and even on both ſides. Corymbs terminal. Segments of the calyx oval, obtuſe. Corolla bell-ſhaped, ſpreading.—Native of the Levant, in moiſt ſhady places. Common in the European gardens, where it blooms magnificently in the open ground in June, and, by forcing in a pot, may be had much earlier, as almoſt every window and balcony in London evinces. This ſhrub is uſually five or ſix feet high, with brown ſpreading *branches*. The *leaves* are evergreen, a ſpan in length, elliptic-lanceolate, or oblong, more or leſs acute; ſhining, dark green, even and ſmooth above; equally ſmooth, but paler beneath, contrary to Willdenow's definition. The large purple *flowers* grow, many together, in large, terminal, corymboſe cluſters. The gardeners obtain mule varieties, ſome of them with deciduous leaves, between this plant and the Azaleas. Tournefort thought the poiſonous quality of the honey about Pontus, mentioned by ancient authors, might be partly owing to this plant; at leaſt this ſeems to be what produced a ſort of honey called *Moenomenon*, becauſe, as Pliny relates, it took away the reaſon of thoſe who ate it. What is generally reported of the honey of Pontus appears, however, by what Tournefort has collected, to belong to that yielded by *Azalea pontica*, our beautiful yellow Azalea; and this is confirmed by what the Turks told him of the dangerous effluvia of the flowers of this laſt mentioned plant.

9. R. *arboreum*. Indian Tree Rhododendrum. Sm. Exot. Bot. v. 1. 9. t. 6.—Leaves elliptic-lanceolate; ſmooth and ſhining above; downy beneath. Corymbs terminal. Capſule of ten cells. Stem arboreous.—Found by lieutenant-colonel Hardwicke, in the Sewalic chain of mountains, which ſeparates the plains of Hindooſtan, from the Himmaleh mountains. It generally grows in foreſts of oak, in elevated ſituations, where the ſoil is black vegetable mould, on a ſtony bed. The flowers appear in March and April; the ſeeds are ripened in May or June. The natives know this tree by the name of *Boorans*, and uſe the wood for the ſtocks of muſquets. The *ſtem* is truly arboreous, riſing in a columnar form to the height of twenty feet; its diameter being from ſixteen to twenty-four inches. The *bark* is light as cork, flaking off in large portions. *Branches* aſcending, crooked and brittle, leafy at their extremities. *Leaves* ſhaped much like the laſt, but diſtinguiſhed by the denſe, white, ſilky downineſs of their under ſurface. *Flowers* in large terminal cluſters, of a rich deep crimſon, of little fragrance and ſhort duration, their *corolla* ſhaped much like the laſt, but we do not find it ſpotted within. Segments of the *calyx* ſhallow. *Germen* elliptical, white and downy, with ten furrows. *Capſule* of the ſame ſhape, with ten cells, an unique inſtance, as far as we know, in the preſent genus; but certainly, all things conſidered, not authoriſing any generic ſeparation of this ſpecies from the reſt. We know not whether the ſeeds of this noble tree have vegetated in England. It would probably ſucceed in the moderate warmth of a conſervatory.

10. R. *maximum*. Laurel-leaved Rhododendrum. Linn. Sp. Pl. 563. Willd. n. 9. Ait. n. 8. Purſh n. 1. Curt. Mag. t. 951. (R. foliis nitidis ovalibus, &c.; Trew Ehret. t. 66. Kalmia foliis lanceolato-ovatis, &c.; Mill. Ic. t. 228.)—Leaves oblong; convex and reticulated above; ſmooth and pale beneath. Corymbs ſurmounted by the branches. Segments of the calyx oval, obtuſe. Corolla bell-ſhaped, ſpreading.—Native of mountainous ſituations in North America, near rivulets and lakes, flowering from June to Auguſt. *Purſh*. Though, according to Mr. Aiton, introduced by Peter Collinſon in 1736, twenty-ſeven years before the *ponticum*, it is beyond compariſon leſs common in our gardens. Botaniſts have not very clearly defined the ſpecific difference between theſe two ſpecies. The *leaves* of the preſent are moſt convex, and more ſenſibly reticulated with minute ſunk veins, on their upper ſide, while the under is ſtill more pale, than in *ponticum*. The *flowers* of the *maximum* are more delicately coloured, having the red and white tints of an apple-bloſſom, while the green and yellow dots on their upper ſegment are ſtrikingly conſpicuous. All their ſegments are more elliptical, concave, and far leſs dilated and wavy than in *ponticum*. The *infloreſcence* moreover is almoſt umbellate, and more denſe, ſtanding between two branches of the preſent year, which always riſe conſiderably above it. There are mule varieties in the gardens between theſe ſpecies. Mr. Purſh mentions two American varieties, or perhaps ſpecies: one with flatter *leaves*, and ſmaller

ſmaller whitiſh flowers: the other much taller, even twenty feet high, with large purple *flowers*, and much larger *leaves*, whoſe two ſides are more alike in colour than the common *maximum*. This laſt variety, which we too have ſeen in Mr. Vere's curious garden at Kenſington Gore, merits further examination, having certainly more reſemblance to *ponticum* than to *maximum*, except its gigantic ſtature, which far exceeds both.

11. R. *punctatum*. Carolina Dotted-leaved Rhododendrum. Willd. n. 10. Ait. n. 9. Purſh n. 2. Andr. Repoſ. t. 36. Venten. Jard. de Cels, t. 15.—Leaves elliptic-oblong, acute; ſmooth above; ſprinkled with minute reſinous dots beneath. Umbels ſurmounted by the branches. Segments of the calyx rounded, very ſhort. Corolla funnel-ſhaped, leprous externally.—Native of the mountains of South Carolina, from whence it was brought to England by the late Mr. John Fraſer, in 1791. It ſucceeds well in our gardens on a peat border, flowering early in the ſummer. This is a much humbler ſhrub than any of the varieties of the *maximum*, though its mode of infloreſcence accords with that ſpecies. The *corolla* is roſe-coloured, dilated and wavy as in *R. ponticum*, but ſmaller; its outſide rough or glandular, as in the *ferrugineum*. The *leaves* are elliptical, coriaceous, acute at both ends; dark green and very ſmooth above; paler, ſomewhat ruſty, and very thickly beſprinkled with glandular reſinous dots, beneath.

12. R. *catawbienſe*. Catawba Rhododendrum. Michaux Boreal-Amer. v. 1. 258. Purſh n. 3 Ait. Hort. Kew. Epit. 373. Curt. Mag. t. 1671.—Leaves oval, rounded at each end, ſmooth, paler beneath. Umbels ſurmounted by the branches. Segments of the calyx elongated. Corolla bell-ſhaped.—Native of the high mountains of Virginia and Carolina, particularly on the head waters of the Catawba river, flowering in May and June. *Purſh*. Mr. Fraſer introduced it here in 1809, and brought a report of the *flowers* being ſcarlet; but they have ſince proved of a pale purpliſh roſe-colour, with very ſlight traces of thoſe green dots within, which make ſo great a part of the beauty of *R. maximum*. The *ſhrub* is of a very humble ſize, hardly three feet high, and flowering before it attains even that height; but all its parts are large. The *leaves* are broad, coriaceous, rounded and blunt at both ends; paler beneath, and very obſcurely dotted on the veins. The ſegments of the *calyx* are ſaid to be remarkably elongated, an eſſential mark of diſtinction, which ought to have been ſhewn in the, otherwiſe excellent, figure. We cannot help wiſhing alſo that the uncouth name, given by Michaux, had not been retained; but who ſhall cleanſe the Augean ſtable of modern botanical nomenclature?

Rhododendrum, in *Gardening*, contains plants of the hardy, deciduous, and evergreen, flowering, ſhrubby kinds, the dwarf roſe-bay, of which the ſpecies cultivated are, the ruſty-leaved rhododendrum (R. ferrugineum); the hairy rhododendrum (R. hirſutum); the dwarf rhododendrum, or roſe-bay (R. chamæciſtus); the purple rhododendrum (R. ponticum); and the broad-leaved rhododendrum (R. maximum).

Method of Culture.—Theſe plants may be increaſed by ſowing the ſeeds, which are very ſmall, as ſoon as poſſible after they are procured, either in a ſhady border, or in pots filled with freſh loam, having them very lightly covered with a little fine mould, and plunging the pots up to their rims in a ſhady border, and in hard froſt covering them with bell or hand-glaſſes; taking them off in mild weather. When they are ſown early in autumn, the plants come up the following ſpring, when they muſt be kept ſhaded from the ſun, eſpecially the firſt ſummer, and duly refreſhed with water; in the autumn following removing them to a ſhady ſituation, on a loamy ſoil, covering the ground about the roots with moſs, to guard them from the froſt in winter and keep the ground moiſt in the ſummer ſeaſon. They may alſo be increaſed from ſuckers or offsets, which they produce plentifully where they grow naturally, but ſeldom in this climate.

And they are very ornamental in the border, clumps, and other parts of ſhrubberies.

Rhododendrum *Cryſanthemum*, golden-flowered rhododendrum, in the *Materia Medica*. The leaves of this ſpecies are uſed in medicine. They are inodorous, and have an auſtere, aſtringent, bitteriſh taſte. Water extracts their virtue either by infuſion or decoction. Theſe leaves are reckoned ſtimulant, narcotic, and diaphoretic. Upon being taken, they firſt increaſe the arterial action and heat of the body, producing diaphoreſis, which effects, according to Dr. Home, are followed by a proportional diminution of excitement: the pulſe in one caſe having been reduced 38 beats. In large doſes, they produce nauſea, vomiting, purging, delirium, and all the ſymptoms of violent intoxication. The plant and its effects were firſt deſcribed by Gmelin and Steller in 1747, as a Siberian remedy for rheumatiſm; but it was not much noticed till after 1779, when Kœlpin ſtrongly recommended it in this diſeaſe, and alſo in gout and lues venerea. It has not been much uſed in this country; but from the reſult of ſome trials of it in Scotland, it obtained a place in the Edinburgh Pharmacopeia. It has been given in the form of decoction, made by boiling ℥iv of the leaves in f℥x of water, in a cloſe veſſel, over a ſlow fire, for 12 hours. The doſe of the ſtrained liquor is from f℥j to f℥ij given twice a day, and generally increaſed. Woodv. Med. Bot. Thomſon's Lond. Diſ.

RHODOLÆNA, in *Botany*, from ῥοδον, *a roſe*, and χλαινα, *a cloak*, or *outer covering*; a genus ſo named by Aubert du Petit-Thouars, in his *Plantes des Iſles d'Afrique*, faſc. 3, becauſe of the fine roſe colour of the flowers, which are ſaid to be very large and ſplendid. *De Theis*.

RHODOMAN, Lawrence, in *Biography*, a learned German, was born, in 1546, at Saſſowerf, in Upper Saxony. He ſtudied at the college of Ilfield, and acquired ſuch a knowledge of claſſical literature, that he became an able inſtructor both in public and private. He taught in ſeveral ſeminaries of learning, and was profeſſor of Greek at Jena ſeven years, and of hiſtory at Wittemberg for four years. He died in 1606, at the age of 60. He was deeply learned in the Greek language; but his chief ſervice to literature was by his Latin verſion of Diodorus Siculus: he was author of a hiſtory of Martin Luther, in Greek verſe, and many other pieces. Bayle.

RHODOMELON, a name given by the ancients to a confection made of roſes, quinces, and honey, uſed as a grateful aſtringent and detergent in many caſes.

RHODON, in *Pharmacy*, from ῥοδον, *roſa*, a name applied to ſome compoſitions, where roſes are the chief ingredient, as *diarrhodon*, *&c.* Hence alſo *rhodoſaccharum*, *i. e. ſugar of roſes*. See Rose.

RHODOPE, in *Biography*, a famous courtezan and player on the flute, in antiquity, was born in Thrace. She was at firſt a ſlave in the ſame houſe as Æſop. Charaxus, the brother of Sappho, was violently enamoured of her, and having purchaſed her, gave her her liberty. She eſtabliſhed herſelf at Mucrates, where ſhe became a courtezan, and amaſſed immenſe riches. Pliny ſays that ſhe built, at her own expence, the moſt beautiful of the Egyptian pyramids; but Herodotus, and Bayle from his authority, reject this tale; nor do they give any more credit to the following ſtory.

One day, when ſhe was bathing, and her attendants watching

watching her clothes, an eagle pounced upon one of her ſhoes, and carrying it away, flew with it to Memphis, where he let it fall near king Pſammiticus. This prince, admiring the beauty of the ſhoe, ordered the officers of his houſehold to ſeek, throughout all Egypt, the perſon to whom the ſhoe appertained. She was found and brought to him; and he eſpouſed her. But how are we to reconcile this fact with her being married to Æſop? It is, however, certain, ſay the Encyclopædiſts, that this fabuliſt, notwithſtanding his deformity and uglineſs, had the art to make himſelf beloved by her.

RHODOPUS GALLINULA, in *Ornithology*, a name given by ſome authors to the bird more uſually known by the name *tringa*.

RHODORA, in *Botany*, ſo called by Linnæus, from ῥοδον, *a roſe*, in alluſion to the colour of its flowers, and probably, at the ſame time, to preſerve an analogy with its near relation *Rhododendrum*.—Linn. Gen. 218. Schreb. 294. Willd. Sp. Pl. v. 2. 603. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 3. 49. Purſh v. 1. 298. Juſſ. 159. Lamarck Illuſtr. t. 364. Claſs and order, *Decandria Monogynia*. Nat. Ord. *Bicornes*, Linn. *Rhododendra*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, minute, of one leaf, with five teeth, permanent. *Cor.* Petals three, unequal; the two lowermoſt lanceolate, equal; the upper one wedge-ſhaped, aſcending, three-lobed, the middle lobe rather longeſt. *Stam.* Filaments ten, thread-ſhaped, declining, the length of the corolla; anthers rounded, two-lobed. *Piſt.* Germen ovate, furrowed, ſuperior; ſtyle thread-ſhaped, declining, rather longer than the ſtamens; ſtigma thickeſt, abrupt, convex. *Peric.* Capſule ovate-oblong, with five furrows, of five cells and five valves, the partitions from the inflexed margins of the valves. *Seeds* numerous, minute.

Eſſ. Ch. Calyx five-toothed. Corolla of three petals, unequal. Stamens declining. Capſule ſuperior, of five cells; the partitions from the inflexed margins of the valves.

1. R. *canadenſis*. Canadian Roſe-bloſſom. Linn. Sp. Pl. 561. Willd. n. 1. Ait. n. 1. L'Herit. Stirp. v. 1. 141. t. 68. Curt. Mag. t. 474. (Chamærhododendros; Duham. Sem. Append. 10. t. 27. f. 2, 3.)—Native of Canada and Newfoundland; very hardy in our gardens, except that, flowering in April and May, its bloſſoms are often injured. Curtis ſays it bears gentle forcing remarkably well. Sir Joſeph Banks brought this ſhrub to England in 1767; but it flowered at Paris, for the firſt time, in March 1756. Duhamel ſuggeſted the propriety of eſtabliſhing it as a new genus, which Linnæus adopted and named; but afterwards, having never ſeen the plant, he ſtruck it out, nor did he aſſign any reaſon for this meaſure. The accuracy of Duhamel is, at length, confirmed, and the *Rhodora* re-eſtabliſhed. The *ſtem* is buſhy, erect, two or three feet high, with round, ſmooth, grey or reddiſh branches, never quite ſtraight. *Leaves* deciduous, alternate, ſtalked, elliptical, acute, entire, veiny, hairy, ſlightly glaucous, about an inch and half long, and half an inch wide. *Flowers* appearing before the leaves, in terminal ſolitary umbels, four or five in each umbel, of a bright elegant roſe colour, with violet *anthers*, inodorous. *Petals* ſpreading, each an inch long. *Capſule* clothed with ruſty down.

RHOE, in *Ancient Geography*, a river of Aſia Minor, in Bithynia.

RHŒADEÆ, in *Botany*, the 27th natural order, among the *fragmenta* of Linnæus; of which there is no explanation in his *Prælectiones*, publiſhed by Giſeke. The genera referred hither, at the end of the Gen. Pl., are *Argemone*, *Chelidonium*, *Papaver*, *Podophyllum*, *Sanguinaria*, *Bocconia*. We place them according to the manuſcript corrections of the author, who has ſubjoined *Cytinus*, *Ariſtolochia*, and *Aſarum*.

This order, without the additions, which certainly do not belong to it, is equivalent to the firſt ſection of Juſſieu's PAPAVERACEÆ. (See that article.) Its name is taken from the Greek appellation of the field poppy, ῥοιας, *Papaver Rhœas* of Linnæus; which was ſo called from ῥεω, *to fall off*, becauſe of the ſhort duration of its petals.

RHŒAS, in *Surgery*, a diminution of the caruncula lachrymalis from diſeaſe.

RHŒTICO, in *Geography*, a mountain of Germany, in the county of Pludentz; 6 miles S. of Pludentz.

RHŒTUM, or RHŒTIUM, in *Ancient Geography*, a town of Aſia Minor, in the Troade, on the coaſt of the Helleſpont. According to Strabo, it was built on an eminence near the tomb of Ajax. The promontory called "Rhœtium" was four miles diſtant from that of Sigæum.

RHŒXUS, a port of Aſia, on the coaſt of Cilicia, at the mouth of the river Sarus. Steph. Byz.

RHŒZIA, in *Geography*, a city of Perſia, in the province of Mingrelia, ſituated on the Hippus, the uſual reſidence of the princes of Mingrelia, but which they changed in ſummer for Taqueri, a very pleaſant ſpot, ſeven verſts S. of Ghoni. In Rhœzia much ſilk is cultivated; and all that is prepared in the other parts of Mingrelia is alſo carried thither, to be ſold or manufactured. The manufacture, however, of that commodity is not well underſtood, as they only make a poor ſort of handkerchiefs, or common taffeties.

RHOGE, in *Ancient Geography*, an iſland on the coaſt of Lycia, placed by Pliny in the vicinity of that of Cyprus. Steph. Byz.

RHOGME, in *Surgery*, a rupture or fracture.

RHOGMOI, in *Ancient Geography*, a port of Aſia, on the coaſt of Cilicia. Steph. Byz.

RHOGOMANIS, or RHOGONIS, a river of Aſia, in the Perſide. Ptolemy places the mouth of this river in the ſouthern part of the Perſide, on the Perſian gulf. According to Nearchus, it was a ſmall river, 200 ſtadia from the river Granis.

RHOITES, the name of a medicine among the ancients, which is a ſort of rob of the juice of pomegranates. Dioſcorides deſcribes it as the ſimple juice of the fruit, evaporated over the fire to the conſiſtence of an extract; but Paulus Ægineta gives the receipt to be three parts juice of pomegranate, and one part honey, boiled to the evaporation of a third part. So that the rhoites of Dioſcorides was a true rob of pomegranates; the other rather honey of pomegranates, like our honey of roſes.

RHOMB. See RHOMBUS.

RHOMBITES, in *Ancient Geography*, a river of Aſiatic Sarmatia. Ptolemy.

RHOMBO, in *Ichthyology*, the name of a peculiar fiſh of the rhombus, or turbot kind, called *rhombus aculeatus* by Aldrovand, Geſner, and other writers. It is a large fiſh, of an aſh-coloured green on the back, and white on the belly. It has no ſcales; but the ſkin of its back is divided by lines, ſomething in the manner of the ſkins of ſnakes. The mouth is very large, and is well furniſhed with teeth; and the palate has a number of tubercles, armed alſo with a ſort of teeth. It feeds on fiſh, and its fleſh is very delicate. It is very common in the markets at Venice, and is caught in the neighbouring ſeas, and in many other places. See PLEURONECTES *Maximus*.

RHOMBOIDÆUS *Major* and *Minor*, in *Anatomy*, names given by Albinus to what he makes two muſcles, though Winſlow and others account it only one. What Winſlow

Winflow calls the inferior portion of the rhomboidalis, Albinus calls rhomboidæus major; and what he calls the upper portion of that mufcle, Albinus calls rhomboidæus minor. See RHOMBOIDEUS.

RHOMBOIDALIS. See RHOMBOIDÆUS.

RHOMBOIDES, in *Geometry*, a quadrilateral figure, whofe oppofite fides and angles are equal, but which is neither equilateral nor equiangular; or, it is an oblique-angled parallelogram.

Such is the figure N O P Q, *Plate* XII. *Geometry*, *fig.* 1. For the method of finding the area of a rhomboides, fee RHOMBUS.

RHOMBOIDES, in *Ichthyology*. See CHÆTODON *Argus*, *Striatus*, &c.

RHOMBOIDEUS, in *Anatomy*, a mufcle of the fhoulder, fo called on account of its fhape; dorfo-fcapulien of Chauffier.

It is a broad, flattened, quadrilateral mufcle, placed obliquely at the lower part of the neck and upper part of the back, and extending from the lower portion of the ligamentum nuchæ, and the fuperior fpinous proceffes of the back, to the bafis of the fcapula. The whole of its fibres go obliquely from the fpine downwards and outwards to the fcapula; thus as it is regularly quadrilateral, it has a correct rhomboid figure. Its pofterior furface is chiefly covered by the trapezius; the latiffimus dorfi lies on a fmall portion of it below; and between thefe two mufcles its fibres are covered by the fkin only. The ferratus fuperior pofticus, fplenius, longiffimus dorfi, facrolumbalis, the ribs, and the external intercoftal mufcles, are covered by its anterior furface. Its upper edge goes from the lower part of the ligamentum nuchæ, obliquely outwards and downwards, to the bafis of the fcapula oppofite to the commencement of the fpine of the bone. In great part of its extent this edge is in contact with the levator fcapulæ. The lower margin reaches from the fpinous procefs of the fourth or fifth dorfal vertebra to the inferior angle of the fcapula. The two edges are nearly of equal length, and parallel to each other. The internal edge is attached to the lower portion of the ligamentum nuchæ, to the laft cervical fpinous procefs, to the four or five fuperior dorfal fpines, and to the interfpinal ligaments of thofe bones. The outer edge is fixed to the bafis of the fcapula, from its inferior angle to above the origin of the fpine, between the fupra and infra fpinatus behind, and the ferratus magnus in front.

The rhomboideus is partly mufcular, partly aponeurotic. Its inner edge is attached by aponeurotic fibres, having the fame direction as the flefhy one, fhort above, and longer below. It is fixed to the upper part of the fcapula by fhort aponeurofes; its infertion in the remainder of the bafis is by an aponeurofis attached only at its upper and lower extremities, leaving a paffage between thefe points for branches of the tranfverfalis colli artery. The mufcular fibres are all directed obliquely from within outwards, and from above downwards.

The mufcle is generally divided into two portions, united by cellular tiffue to a fuperior fmaller, and an inferior larger one: thefe are called the rhomboideus minor and major.

By drawing the bafis of the fcapula obliquely upwards and backwards, the rhomboideus carries the inferior angle towards the fpine, and makes the anterior angle of the bone, conftituting the fhoulder, roll forwards and downwards. Thus it reftores the fcapula to its fituation after the fhoulder has been raifed. It concurs in this action with the levator fcapulæ.

RHOMBOIDIA, in *Natural Hiftory*, the name of a genus of fpars, given them from their being of a rhomboidal form. They owe this figure to an admixture of particles of iron, and confift of fix planes.

Of this genus there are only two known fpecies, *viz.* a white thin one with very thin crufts, and a whitifh-brown thick one with thicker crufts. They are both found in the foreft of Dean in Gloucefterfhire, and in other places, where there are iron-ores. Hill.

RHOMBUS, Ῥομβος, is formed of ῥομβος, of ῥομβειν, *to encompafs* or *turn round*, in *Geometry*, an equilateral rhomboid; or a quadrilateral figure, whofe fides are equal and parallel, but the angles unequal; two of the oppofite ones being obtufe, and the other two acute. Such is the figure A B C D, *Plate* X. *fig.* 11.

To find the Area of a Rhombus, or Rhomboides.—Upon C D, which is here affumed as a bafe, let fall a perpendicular A E, which will be the altitude of the parallelogram: multiply the bafe by the altitude, the product is the area. Thus, if C D be $= 456$, and A E $= 234$, the area will be found 106704.

For it is demonftrated, that an oblique-angular parallelogram is equal to a rectangle upon the fame bafe C D, and of the fame altitude A E (fee PARALLELOGRAM). But the area of a rectangle is equal to the factum of the bafe into the altitude; therefore the area of an oblique-angular parallelogram is equal to the fame. See RECTANGLE.

The area of a parallelogram, rhombus or rhomboides, may be found by means of the following proportion: As radius, *i. e.* fine of 90° or tangent of 45°, is to the fine of any angle of a parallelogram, fo is the product of the fides including the angle to the area of a parallelogram: that is, $AD \times DC \times$ nat. fine of the angle $D =$ the area. For having drawn the perpendicular A E, the area, by the firft rule, is $AE \times DC$; but as rad. 1 (fin. $< E$) : fin. $< D$ :: $AD : AE =$ fin. $< D \times AD$; therefore $AE \times DC = DC \times$ fin. $< D \times AD$ is the area; or, 1 : fin. $< D$ :: $AD \times DC$: fin. $< D \times AD \times DC =$ the area of the parallelogram.

N.B. As the angles of a fquare and rectangle are each 90°, whofe fine is 1, this rule is the fame as the former.

E. G. 1. What is the area of a rhomboides, whofe length is 36 feet, flope-height 25.5 feet, and one of the lefs angles 58°? Here rad. or 1 : .8480481 (nat. fine of 58°) :: 918 ($= 25.5 \times 36$) : 778.5081558, the area. Or, by ufing the logarithms, rad. (10.0000000) : fin. 58° (9.9284205) :: log. of 918 (2.9628427) : 778.5081, the number correfponding to the log. (2.8912632).

2. What is the area of a parallelogram whofe angle is 90°, and the including fides 20 and 12.25 chains? Anf. 245 acres.

3. What is the area of a rhombus, each of whofe fides is 21 feet 3 inches, and each of the lefs angles 53° 20′? Anf. 362.208757 feet.

4. How many acres are in a rhomboides whofe lefs angle is 30°, and the including fides 25.35 and 10.4 chains? Anf. 13 acres 29.12 perches.

The area of either of the forementioned figures may alfo be had by the following rule, which is common to all quadrilaterals. As radius is to the fine of the angle which the interfecting diagonals of a parallelogram make with each other, fo is the product of the diagonals to double the area: that is, $\frac{AC \times BD \times \text{nat. fine of the angle } R}{2} =$ the area.

N. B. Becaufe the diagonals of a fquare and rhombus interfect at a right angle, whofe fine is 1, half the product of their diagonals is the area; that is, $\frac{1}{2} AC^2$ in the fquare and $\frac{1}{2} AC \times BD$ in the rhombus is the area.

E. G.

E. G. 1. How many acres are in a piece of land, in the form of a rhombus, whose diagonals are 30 and 20 chains? Anf. 30 acres.

2. How many yards of painting are in a rectangle, whose diagonals, interfecting in an angle of 30°, are each 32 feet? Anf. $28\frac{4}{9}$.

3. What is the area of a rhomboides, whose diagonals, making an angle of 60°, are 30 and 25 feet? Anf. 324.7595 feet. Hutton's Menfuration.

RHOMBUS, *Solid*, two equal and right cones joined together at their bafes.

RHOMBUS, in *Ichthyology*, a fpecies of the *Pleuronectes*; which fee. See alfo PLEURONECTES *Maximus* and TURBOT, and P. *Paffer*.

RHOMBUS, in *Conchology*, the name given by the generality of authors to a genus of the fhell-fifh, much more properly called by fome *cylindrus*.

RHOMBUS, among *Surgeons*, denotes a fort of bandage of a rhomboidal figure.

RHON, in *Ancient Geography*, a river of India, among the people called Gandarii. Steph. Byz.

RHONDE, in *Geography*. See RONDE.

RHONE, a river of France, formed by the union of three fprings, which rife in mount Sufberg, a part of the Grimfell, at the eaftern extremity of the Valais. It paffes through the lake of Geneva to Seiffel, &c. and thence to Lyons, where it joins the Sâone, and after watering Vienne, Valence, Viziers, Avignon, Arles, &c. difcharges itfelf by feveral mouths into the Mediterranean.

RHONE, *Mouths of the*, *Bouches de Rhône*, one of the twelve departments of the S.E. region of France, bounded on the N. by the county of Venaiffin, on the N.E. by the department of the Lower Alps, on the E. by the department of the Var, on the S. by the Mediterranean, and on the W. by the department of the Gard: 5315 kiliometres in extent, or 269 fquare leagues, and containing a population of 320,072 perfons. It is divided into three circles or diftricts, including 26 cantons and 108 communes. The circles are, Marfeilles, having 142,058 inhabitants; Aix, 97,938; and Tarafcon, 80,076. According to M. Haffenfratz, its extent in French leagues is 30 in length and 20 in breadth; its circles are 5, its cantons are 40, and its population confifts of 446,643 perfons. It is a portion of Lower Provence, and lies in N. lat. 43° 40′. Its capital is Aix. Its contributions to the land-tax, &c. amounted, in the 11th year of the French era, to 3,612,199 fr.; and its expences, adminiftrative, judiciary, and for public inftruction, to 354,531 fr. 33 cents. Many of the hills in the northern diftricts are bare rocks, deftitute of foil and verdure. The chief productions of the department are grain, wine, filks, olives, fruits, and paftures. It has mines of iron, alum, vitriol, with quarries of marble, &c. Pools and marfhes are difperfed near the coaft.

RHONE, or *Rhone and Loire*, one of the eleven departments of the E. region of France, bounded on the N. by the department of the Sâone and Loire, on the E. by the departments of the Ain and the Ifere, on the S. by the departments of the Ardêche and the Upper Loire, and on the W. by the departments of the Puy de Dôme and the Allier: to the E. it is bounded by the river Rhine, and the Loire paffes nearly through its centre from N. to S. Its extent is 2935 kiliometres, or 147 fquare leagues, and its population confifts of 345,644 perfons. It is divided into 2 circles, 25 cantons, and 261 communes. Its circles are Villefranche, including 106,262 inhabitants, and Lyons, having 239,382. According to Haffenfratz, its extent in French leagues is 20 in length, and 9 in breadth; its circles are 2, its cantons 32, and its population is 323,177. It lies in N. lat. 46° between Ain and Loire, and comprehends the provinces formerly called Lyonnais and Beaujolais. Its capital is Lyons. The plains yield fcanty crops of grain and pafture; the gentle eminences are covered with vineyards, and the fummits of the mountains are clothed with pines. This department has mines of copper, lead, coal, quarries of marble, freeftone, &c.

RHOPALA, in *Botany*, a name altered by Schreber from the *Roupala* of Aublet, which, being of barbarous origin, and unexplained by the publifher, he contrived, by the above alteration, to derive from ῥόπαλον, *a club*, or *ftake*. This may very well apply to the fize and nature of the woody ftem, which rifes to the height of three or four feet, before it fends off any branches. Vahl and Willdenow have contrived to retain the barbarifm, without adding any thing to the fenfe.—Schreb. 62. Brown. Tr. of Linn. Soc. v. 10. 190. (Roupala; Aubl. Guian. v. 1. 83. Juff. 79. Lamarck Illuftr. t. 55. Gærtn. fuppl. t. 217. Rupala; "Vahl Symb. v. 3. 20." Willd. Sp. Pl. v. 1. 536.)—Clafs and order, *Tetrandria Monogynia*. Nat. Ord. *Proteaceæ*, Juff. Brown.

Gen. Ch. *Cal.* none. *Cor.* Petals four, fpatulate, regular, concave, recurved at the extremity. Nectary of four glands, feparate or combined, at the bafe of the germen. *Stam.* Filaments four, fhort, inferted above half way up the petals; anthers oblong, two-lobed, projecting beyond their recurved extremities. *Pift.* Germen fuperior, ovate, with rudiments of but two feeds; ftyle awl-fhaped, permanent, the length of the corolla; ftigma vertical, club-fhaped, undivided. *Peric.* Follicle ovate, fomewhat woody, of one cell. *Seeds* two, bordered, winged at each end, the kernel central.

Eff. Ch. Calyx none. Petals four, regular, recurved. Stamens inferted into the middle of each petal. Nectary of four glands. Stigma vertical, club-fhaped. Follicle of one cell. Seeds two, bordered, winged at each end.

The habit of the genus is arborefcent. *Leaves* alternate, rarely whorled; fimple, entire or toothed, rarely pinnate, or ternate, on the fame branch. *Spikes* axillary, fometimes terminal, racemofe, the *flowers* in pairs with a fingle *bractea* to each pair.

1. R. *montana*. (Roupala montana; Aubl. Guian. v. 1. 83. t. 32. Lamarck t. 55. Rupala montana; Willd. n. 1.)—Leaves alternate, entire, ovate, folded, fhort-pointed, reticulated with veins. Spikes axillary, folitary, longer than the leaves. Flower-ftalks, petals and germen clothed with rufty down.—Native of the Serpent Mountain in Guiana, flowering in Auguft. *Aublet.* A fmall *tree*, feven or eight feet high; its trunk three or four feet. *Bark* wrinkled and cracked, whitifh, as well as the *wood*. Both exhale, when cut, a ftrong fetid fcent, like that of the ferpents of the fame country. *Leaves* fmooth, of a firm dry texture, about three inches long. *Footftalks* an inch long, inflated at the bafe. *Flowers* about eight or ten alternate feffile pairs, in each lax *fpike*.

2. R. *media*. Brown n. 2.—Leaves alternate, entire, ovate, flat, pointed, running down the footftalk, with depreffed veins. Clufters axillary, folitary, longer than the leaves. Partial flower-ftalks and petals fomewhat hairy. Germen downy.—Gathered in the fame country by Von Rohr, who fent fpecimens to fir Jofeph Banks. This feems very nearly related to the foregoing.

3. R. *nitida*. Br. n. 3. (Ropala nitida; Rudge Guian. v. 1. 26. t. 39.)—Leaves alternate, entire, elliptical, fhort-pointed, flat. Clufters axillary, folitary, about the length of the leaves. Partial flower-ftalks, petals and germen fmooth.—Gathered by Jofeph Martin in Guiana. *Brown.*

4. R.

4. R. *moluccana* Br. n. 4.—Leaves alternate, entire, elliptical, flat, finely veined, somewhat reticulated, longer than the clusters. Partial flower-stalks and petals smooth.—Gathered in the Molucca islands, by the late Mr. Christopher Smith. *Herb. Banks.*

5. R. *cochinchinensis.* Br. n. 5. (Helicia cochinchinensis; Lour. Cochinch. 83, on the authority of a specimen seen by Mr. Brown, in sir Joseph Banks's collection, from the author.)—Leaves alternate, elliptic-ovate, short-pointed, flat, somewhat serrated above half way down. Clusters axillary, solitary, about the length of the leaves. Partial flower-stalks, petals and germen smooth.—Native of woods in Cochinchina. (See Helicia.) Mr. Brown observes, that what Loureiro describes as a four-cleft *calyx*, are really the nectariferous glands, united at their base, and remaining after the petals are fallen. Such a mistake might well render his description unintelligible, without a sight of the plant.

6. R. *serrata.* Br. n. 6.—Leaves alternate, broadly elliptical, scarcely pointed, serrated; somewhat contracted and entire at the base; paler beneath. Clusters axillary, solitary, shorter than the leaves. Partial flower-stalks, petals and germen downy.—Gathered by Mr. Christopher Smith in the Molucca isles.

7. R. *dentata.* Br. n. 7.—Leaves alternate, ovato-lanceolate, folded, toothed, tapering at each end; with a linear point. Clusters axillary, solitary, rather longer than the leaves. Petals and germen downy.—Gathered by Mr. Alexander Anderson in Guiana. *Herb. Banks.*

8. R. *peruviana.* Br. n. 8. ("Embothrium monospermum; Fl. Peruv. et Chil. v. 1. 63. t. 98.")—Leaves alternate, ovate, serrated, woolly; rusty beneath. Clusters axillary, solitary, longer than the leaves.—Native of the colder mountains of Peru.

9. R. *diversifolia.* Br. n. 9. ("Embothrium pinnatum; Fl. Peruv. et Chil. v. 1. 63. t. 99.")—Leaves alternate, simple or pinnate, very veiny; downy beneath. Clusters axillary, solitary, longer than the leaves. Follicles cimeter-shaped, downy.—Native of waste ground, and the borders of fields, in Peru.

10. R. *sessilifolia.* Br. n. 10. (Roupala sessilifolia; Richard Act. Soc. Hist. Nat. Par. v. 1. 106. Poiret in Lamarck Dict. v. 6. 316. Rupala sessilifolia; Willd. n. 2. Ropala hameliæfolia; Rudge Guian. v. 1. 22. t. 31.)—Leaves four in each whorl, nearly sessile, oblong, somewhat wedge-shaped, slightly pointed, entire. Clusters terminal, umbellate. Flowers whorled.—Native of Guiana. The *leaves* are, in the figure, precisely obovate, tapering at the base, a span long. *Clusters* about the same length, erect, stalked, forming an umbel at the top of the branch or stem; their partial stalks hairy, imperfectly whorled, very numerous.

RHOPALIC Verses, among the *Ancients*, a kind of verses which began with monosyllables, and were continued in words growing gradually longer and longer to the last, which was the longest of all.

They had their name from the Greek ῥόπαλον, *a club*, which, like them, begins with a slender tip, and grows bigger and bigger to the head. Such is that verse of Homer:

Ω μάκαρ Ατρείδη μοιρηγενὲς, ὀλβιόδαιμον.

And this Latin one of Ausonius:

"Spes deus æternæ stationis conciliator."

RHOPALOSIS, a distemper of the hair described by the ancients, and seeming to be the same with what we call the *Plica Polonica*; being a sort of matting together of the hair into long and thick tresses.

RHOPE, formed of ῥέπω, *to preponderate*, a word used by the Greek writers to express a violent tendency of the humours to any particular part of the body.

RHOPIUM, in *Botany*, from Ῥώπιον, *a slender shoot*, the flower-stalks of this plant having a delicate, twiggy appearance.—Schreb. 608. Willd. Sp. Pl. v. 4. 150. (Meborea; Aubl. Guian. 826. Juss. 437. Lamarck Illustr. t. 731.)—Class and order, *Gynandria Triandria.* Nat. Ord. *Euphorbiæ*, Juss. See Meborea.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, permanent, cloven into six, lanceolate, acute segments, each having a little bordered cavity at the base. *Cor.* none. *Stam.* Filaments none; anthers three, cloven, each adhering to a single style under the stigma, with distant cells, bursting transversely. *Pist.* Germen superior, roundish or triangular; styles three, erect, approximated; stigmas flat, acute, bent down over the anthers. *Peric.* Capsule composed of three obtuse-angled lobes, with six cells, and six valves: partitions from the middle of the valves. *Seeds* two, one adhering to each side of the partition, ovate.

Eff. Ch. Calyx six-cleft. Corolla none. Anthers three, with remote cells, and placed in the middle of the styles. Styles three. Capsule three-lobed, of three cells, each with two seeds.

1. R. *citrifolium.* Willd. (Meborea guianensis; Aubl. Guian. t. 323.)—Native of woods in Guiana, where it flowers and bears fruit in January. The *stem* of this shrub is from three to four feet in height, branched towards the summit. *Leaves* alternate, ovate, acute, smooth, entire, nearly sessile. *Stipulas* twin, small, deciduous. *Flowers* corymbose, axillary and terminal, of a yellowish-green colour, each standing on a long, slender stalk, which is furnished with a scale at its base.

RHOPOGRAPHI, Ῥωπογράφοι, formed of ῥῶπος, *toys* or *odd ware*, and γράφω, *I paint*, in *Antiquity*, an appellation given to certain painters, who confined themselves to low subjects, such as animals, plants, landscapes, &c.

The same appellation has been also given to such as cut figures of men, &c. in box, phillyrea, yew, &c. in gardens.

RHOSOLOGIA, in *Ancient Geography*, a town of Asia, in Galatia, in the country of the Teitsages, between Venzala and Sarmalia. Ptolemy.

RHOSOS, a town situated on the gulf of Issus, at the eastern extremity of the Mediterranean sea, between two defiles, one of which led to Syria, and was called the "gates of Syria;" and the other formed by mount Amanus and the sea-coast, communicating with Cilicia, and called the "Amanic gates." Ptolemy places this town in Syria, and Strabo places it in Cilicia. After the death of Seleucus Nicator, Demetrius caused the statue of Fortune to be conveyed hither. It was famous for the manufacture of earthen vessels, mentioned by Cicero, when he was governor of Cilicia, in a letter to Atticus. Sapor, king of Persia, burnt this city, after he had taken prisoner the emperor Valerian, A.D. 260. It was pillaged under the reign of Arcadius, in the year 404, by the Isaurians, a savage people, who inhabited the mountains. Jupiter was worshipped in this town; and the statue of this deity was engraven on the medals of Rhosos.

RHOSSICUS Scopulus, a promontory of Asia, in Syria, near the gulf of Issicus.

RHOT, in *Geography*, a river of Switzerland, which runs into the Aar, 5 miles W. of Zoffingen.

RHOTANUM, in *Ancient Geography*, a river of Corsica, the mouth of which is placed by Ptolemy on the eastern side, between Valeria Colonia and the port of Diana.

RHOX, a word ufed by fome authors to exprefs the tunica uvea of the eye.

RHUBARB, Rhabarbarum, in *Botany*. See Rheum.

Rhubarb, *Rheum Palmatum*, in the *Materia Medica*. The rhubarb, called the rhabarbarum officinale, was fuppofed, in the year 1732, to be fupplied by fome plants fent from Ruffia, to Juffieu of Paris, Rand at Chelfea, and Linnæus at Upfal. Accordingly thefe plants were adopted by Linnæus, in his firft edition of the Species Plantarum, under the name of rheum rhabarbarum. This, however, was not very generally received as the genuine rhubarb plant. But in order to afcertain this matter more completely, Kauw Boerhaave procured, from a Tartarian rhubarb merchant, the feeds of thofe plants, which he annually fold, and which were admitted at Peterfburgh to be the true rhubarb. Thefe feeds were foon difcovered by de Gorter to produce two diftinct fpecies; *viz.* the R. rhabarbarum of Linnæus, or R. undulatum, as it has been fince called; and another fpecies, declared by Linnæus to be a new one, and firft mentioned in the fecond edition of the Species Plantarum, in 1762, under the name of R. palmatum. But before this time, de Gorter had repeatedly fent its feeds to Linnæus, and the young plants conftantly perifhed: at length he obtained the frefh root, which fucceeded very well at Upfal, and enabled the younger Linnæus to defcribe this plant in the year 1767. However, two years antecedent to this, Dr. Hope's account of the rheum palmatum, as it grew in the Botanic garden near Edinburgh, had been read before the Royal Society at London; and of the great eftimation in which this plant was held by him we have the following proof. "From the perfect fimilarity of this root with the beft foreign rhubarb in tafte, fmell, colour, and purgative qualities, we cannot doubt our being at laft poffeffed of the plant which produces the true rhubarb, and may reafonably entertain the agreeable expectations of its proving a very important acquifition to Britain." (See Phil. Tranf. for the year 1765.) But from the relation above given, it appears that the feeds of both R. undulatum and R. palmatum were tranfmitted to Peterfburgh as thofe of the true rhubarb: we are therefore to conclude, that the former fpecies has an equal claim to this importance with the latter; and from further inquiries made in Ruffia, there is the beft authority for believing that the R. compactum alfo affords this very ufeful drug. Bergius fays, "Rheum palmatum producit *rhabarbarum* in officinis *Sibiricum* appellatum: certe e feminibus a Bucharis e montofis Tibeti in Ruffiam apportatis, et poftea fatis hocce rheum palmatum enatum eft." (Vide Pallas Reife, &c. vol. iii. p. 157.) "*Rhabarbarum* vero *Chinenfe* ex alia fpecie rhei defumptum effe videtur." (Vide Georgi Reife, &c. vol. i. p. 211.) The feeds of the rheum palmatum were firft introduced into Britain in 1762, by Dr. Mounfey, who fent them from Ruffia, and were fuppofed to be a part of thofe already mentioned; and fince their profperous cultivation by the late profeffor of botany at Edinburgh, the propagation of this plant has been gradually extended to moft of our Englifh gardens, and with a degree of fuccefs which promifes in time to fuperfede the importation of the foreign root. The R. rhaponticum is a different fpecies from either of thefe. This is fuppofed to be the rhabarbarum of the ancients. It is well known that the ancient rhubarb had not the purgative virtues of the modern. Two forts of rhubarb are ufually imported into this country for medical ufe, *viz.* the Chinefe and the Tartary rhubarb. Mr. Bell informs us, in his travels, that the beft rhubarb grows in that part of the Eaftern Tartary called Mongallia, which ferves as a boundary between Ruffia and China; or, on the chain of mountains in Tartary, which ftretches from the Chinefe town Selin to the lake Kokonor, near Thibet. This plant, he fays, does not run and fpread itfelf like docks, but grows in tufts at uncertain diftances, as if the feed had been dropped with defign. As the Mongalls do not think it worth cultivating, the marmots, which burrow under the fhade of its fpreading leaves, and probably feed on its leaves and roots, contribute to its increafe, partly by the manure which their dung affords it, and principally by cafting up and loofening the earth, into which the ripe feeds, blown by the wind, fall, and where they immediately take root. After digging and gathering the rhubarb, the Mongalls cut the large roots into fmall pieces, in order to make them dry the more readily. The roots are taken up in autumn, according to Mr. Bell's account; but according to Pallas, in April and May: and after being cleaned, and cut tranfverfely into pieces of a moderate fize, thefe pieces are placed on tables, and turned three or four times a day for five or fix days. In the middle of every piece they fcoop a hole, through which a cord is drawn, in order to fufpend them in a convenient place, but fheltered from the fun, and expofed to the air and wind; and by this practice they deftroy fome of the beft part of the root.

The proper exficcation of this root is certainly attended with great difficulty, and the cultivators of rhubarb in this country have not yet agreed as to the beft mode of accomplifhing it. The recent root, in this procefs, according to the experiment of fir William Fordyce, lofes nearly ninetenths of its weight; and as others fay, feven-eighths. In China the roots are not dug up till winter; and the cultivators, after cleaning, fcrape off the bark, and cutting them, dry the flices by frequently turning them on ftone flabs, heated by a fire underneath; after which, the drying is completed by hanging them up in the air, expofed to the greateft heat of the fun. Part of the Tartarian rhubarb is carried to Turkey through Natolia; but the greateft part is conveyed by the Bucharians to Kiachta, on the Ruffian frontier, where it is examined by a Ruffian apothecary, and the beft pieces only are felected and fent to Peterfburgh. The Chinefe is conveyed to Canton, and there purchafed by the agents of the Eaft India Company.

Of the two forts of rhubarb above mentioned, the Chinefe is chiefly obtained in the province of Xenfi or Shenfee, under the name "Taihoung." It comes immediately from the Eaft Indies, in oblong pieces, flattifh on one fide, and convex on the other; compact, hard, heavy, internally of a dull red colour, variegated with yellow and white; and when recently powdered, appears yellow; but on being kept, becomes gradually redder. The fecond is the moft valuable, and is brought to us from Turkey and Ruffia, in roundifh pieces, with a large hole through the middle of each; it is more foft and friable than the former fort, and exhibits, when broken, many ftreaks of a bright red colour. This fort, unlefs kept very dry, is apt to grow mouldy and worm-eaten; the other is lefs fubject to thefe inconveniences. Some of the more induftrious artifts are faid to fill up the worm-holes with certain mixtures, and to colour the outfide of the damaged pieces with powder of the finer forts of rhubarb, and fometimes with cheaper materials. The marks of the goodnefs of rhubarb are, the livelinefs of its colour when cut, its being firm and folid, but not flinty or hard; its being eafily pulverable, and appearing, when powdered, of a fine bright yellow colour; its imparting to the fpittle, on being chewed, a deep faffron tinge, and not proving flimy or mucilaginous in the mouth. Its tafte is fubacrid, bitterifh, and fomewhat ftyptic; the fmell is flightly aromatic.

Turkey rhubarb is generally preferred to the Eaſt India ſort, though the latter is more aſtringent, but has ſomething leſs of an aromatic flavour. Tinctures made from both, with equal quantities of rectified ſpirit, have nearly the ſame taſte; on drawing off the menſtrua, the extract left by the tincture of the Eaſt India rhubarb proves in taſte conſiderably ſtronger than the other. They ſeem both, ſays Dr. Lewis, to be the produce of the ſame climate, and roots of the ſame ſpecies of plant, taken up probably at different ſeaſons, or cured in a different manner. Lewis's Mat. Med.

The Ruſſian rhubarb and Turkey rhubarb, ſometimes diſtinguiſhed in the ſhops, ſeem to be the root of the ſame ſpecies of plant, grown in the ſame place, and prepared in the ſame manner; but Mr. A. T. Thomſon (Lond. Diſp.) inclines to believe, that the Eaſt Indian is the root of a different ſpecies, very probably of the "undulatum;" and the mode of preparation appears to be evidently different, from the aſpect of the pieces.

Good Ruſſian or Turkey rhubarb, ſays Mr. Thomſon, has a peculiar, ſomewhat aromatic odour, and a bitter, ſlightly aſtringent, ſubacrid taſte; feels gritty between the teeth when chewed, and tinges the ſaliva of a bright yellow colour. It breaks with a rough hackly fracture, is eaſily pulverized, and affords a powder of a bright buff yellow colour. Water at 212° takes up 24 parts in 60; the infuſion is of a brown colour, nearly clear, and reddens litmus paper. Alcohol extracts 2.7 from 10 parts, and gives a tincture of a rich golden colour, which reddens tincture of litmus; is not altered in its tranſparency by the addition of water; and ſtrikes a blackiſh olive hue with ſolution of ſulphate of iron, but no immediate precipitate falls. Sulphuric ether takes up 1.5 in 10 parts of this rhubarb; the tincture is of a golden yellow hue, and when evaporated on water, leaves a thin pellicle of yellow reſin, and abundance of extractive diſſolved in the water, combined, however, with tannin. Eaſt Indian or Chineſe rhubarb has a ſtronger odour, and is more nauſeous to the taſte than the Turkey; breaks with a more compact and ſmoother fracture; and affords a powder of a redder ſhade. Water takes up 30 parts in 60; the infuſion is not ſo deep coloured as that of Ruſſian rhubarb, more turbid, and reddens alſo litmus paper. Alcohol extracts 4 parts in 10; the tincture is of a much deeper colour, and browniſh; gives a deeper red to litmus tincture; is rendered ſlightly turbid by the addition of water; and ſtrikes a green, not black, olive with ſulphate of iron, which it alſo quickly and copiouſly precipitates. Ether takes up 2 parts in 10; the tincture is deeper coloured, and when evaporated on water, affords the ſame reſults as the former kind, except that the compound of tannin and extractive is more ſoluble.

The infuſion of Chineſe rhubarb is more copiouſly precipitated by ſolution of iſinglaſs than that of the Ruſſian. Infuſion of yellow cinchona throws down a copious greeniſh precipitate from infuſion of Ruſſian rhubarb, and a leſs copious, but more denſe, bright yellow precipitate from that of Chineſe rhubarb.

The following tables ſhew the effects of re-agents on the aqueous infuſion of the two varieties of rhubarb.

Table I.—Precipitates formed by Acids, Alkalies, and Neutral Salts.

Variety of Rhubarb.	Sulphuric Acid.	Nitric Acid.	Muriatic Acid.	Oxymuriatic Acid.	Solution of Potaſs.	Solution of Subcarbonate of Potaſs.	Lime Water.	Muriate of Barytes.	Silicated Potaſs.
Ruſſian.	copious, greeniſh-yellow.	ſcanty, flocculent, pale yellow.	ſcanty, very ſlowly formed, yellow.	ſlowly formed, pale olive.	none, but ſtrikes a deep lake colour.	none, but ſtrikes a reddiſh-brown.	ſcanty, ſlowly formed, brown.	ſcanty, olive-green.	none, but ſtrikes a deep brown.
Chineſe.	more copious, browniſh-yellow.	leſs ſcanty, pale yellow.	ſcanty, quickly formed, browniſh-yellow.	ſlowly formed, orange-yellow.	none, a deeper lake.	none, but renders it turbid, and deep reddiſh-brown.	copious, quickly formed, brown.	leſs ſcanty, orange-yellow.	none, but ſtrikes a deep brown.

Table II.—Precipitates formed by Solutions of Metallic Salts.

Variety of Rhubarb.	Solution of Oxyſulphate of Iron.	Solution of Nitrate of Silver.	Solution of Nitrate of Mercury.	Solution of Nitrate of Lead.	Solution of Muriate of Mercury.	Solution of Acetate of Lead.	Solution of Tartarized Antimony.
Ruſſian.	copious, nearly black.	ſcanty, pale greeniſh-yellow.	copious, olive-yellow.	ſcanty, ſlowly formed, yellow.	ſcanty, ſlowly formed, pale olive.	ſcanty, greeniſh-yellow.	ſcanty, ſlowly formed, whitiſh.
Chineſe.	copious, deep olive-green.	copious, orange-yellow.	copious, heavy, bright yellow.	ſcanty, ſlowly formed, deeper yellow.	copious, quickly formed, heavy yellow.	copious, yellow.	ſcanty, ſtill more ſlowly formed.

When the refidue, after the action of water, is digefted in muriatic acid, and folution of ammonia added in excefs, the liquid becomes milky, and depofits oxalate of lime. What remains confifts of woody matter, a fmall portion of alumen, and filex. Of the fpecimens which we examined, one drachm of the Ruffian rhubarb yielded twenty-fix grains of the oxalate, while the fame weight of Eaft Indian yielded only eighteen grains.

From the refults of the above experiments, rhubarb appears to contain a large portion of extractive matter, a fmall portion of refin, mucus, tannin, gallic acid, a colouring matter, oxalate of lime, and minute proportions of alumen and filex. They fhew that the two varieties differ from each other in feveral refpects. The Ruffian contains more tannin, oxalate of lime, and refin; the Chinefe more extractive and gallic acid. But the purgative principle is ftill unafcertained, although it appears to be combined with the extractive, and hence is foluble in water.

The yellow colour of rhubarb, it is faid, is much lefs deftructible than many other vegetable yellows. Aqua fortis, and other acids which deftroy the colour of faffron, turmeric, &c. make no change in that of rhubarb, or at moft render it only turbid. Volatile fpirits heighten the colour, and incline it to red. Fixed alkaline falts have this effect in a greater degree. Mr. Model affirms that a confiderable quantity of felenites is contained in rhubarb. In one experiment he obtained fix ounces of felenites from four pounds of rhubarb; and in the other, no lefs than an ounce of felenites from two ounces and five drachms of old rhubarb. Rozier's Journal for July, 1775.

Rhubarb is a mild cathartic, and commonly confidered as one of the fafeft and moft innocent of the fubftances of this clafs. Befides its purgative virtue, it has a mild aftringent one, difcoverable by the tafte, and by its ftriking an inky blacknefs with chalybeate folutions: hence it is found to ftrengthen the tone of the ftomach and inteftines, to leave the belly coftive, and to be one of the moft ufeful purgatives in diarrhœas, dyfenteries, and all diforders proceeding from a debility and laxity of the fibres: it is frequently given with a view to this ftomachic and corroborating virtue, rather than to its producing any confiderable evacuations. It tinges the urine of a high yellow colour. Rhubarb in fubftance purges more effectually than any preparation of it: the dofe is from a fcruple to a drachm. From ℈j to ʒß of the powdered root opens the bowels freely; and from grs. vi to grs. x may be given for a dofe, when its ftomachic properties only are required. By roafting it with a gentle heat, till it becomes eafily friable, its cathartic power is diminifhed, and its aftringency fuppofed to be increafed. The purgative virtue of rhubarb is extracted more perfectly by water than by rectified fpirit; the root remaining after the action of water is almoft, if not wholly, inactive; whereas, after repeated digeftion in fpirit, it proves ftill very confiderably purgative: when the rhubarb has given out to fpirit all that this menftruum can extract, it ftill imparts a deep colour, as well as a purgative impregnation, to water. A drachm of the extract, formed by infpiffating the watery infufion, is not more efficacious than a fcruple of the root in fubftance; but half a drachm of the extract, formed from the fpirituous tincture, proves moderately purgative, though fcarcely more fo than an equal quantity of the powder. The fpirituous extract diffolves almoft wholly in water; and hence the tincture, like the fpirituous infufions of moft other vegetables, does not turn milky on being mixed with aqueous liquors: of the watery extracts fcarce above one-fourth is diffolved by rectified fpirit, and the part that does not diffolve proves more purgative than that which does. Hence it appears, that rhubarb contains much more gummy or mucilaginous than refinous matter; and its purgative quality feems to refide chiefly in a combination of gummy and faline matter.

"The qualities of this root," fays Dr. Cullen (Mat. Med. vol. ii.), "are that of a gentle purgative, and fo gentle that it is often inconvenient by reafon of the bulk of the dofe required, which in adults muft be from half a drachm to a drachm. When given in a large dofe, it will occafion fome griping, as other purgatives do; but it is hardly ever heating to the fyftem, or fhews the other effects of the more draftic purgatives. The purgative quality is accompanied with a bitternefs, which is often ufeful in reftoring the tone of the ftomach, when it has been loft; and for the moft part, its bitternefs makes it fit better on the ftomach than many other purgatives do. Its operation joins well with that of neutral laxatives; and both together operate in a leffer dofe than either of them would do fingly.

"Some degree of ftipticity is always evident in this medicine; and as this quality acts when that of the purgative has ceafed, fo in cafes of diarrhœa, when any evacuation is proper, rhubarb has been confidered as the moft proper means to be employed. I muft, however, remark here, that in many cafes of diarrhœa, no further evacuation than what is occafioned by the difeafe is neceffary or proper. The ufe of rhubarb in fubftance for keeping the belly regular, for which it is frequently employed, is by no means proper, as the aftringent quality is ready to undo what the purgative had done; but I have found that the purpofe mentioned may be obtained by it, if the rhubarb is chewed in the mouth, and no more is fwallowed than what the faliva has diffolved. And I muft remark, in this way employed it is very ufeful to dyfpeptic perfons. Analogous to this is the ufe of rhubarb in a folution, in which it appears to me that the aftringent quality is not fo largely extracted as to operate fo powerfully, as when the rhubarb was employed in fubftance."

The operation of rhubarb is quickened by the addition of neutral falts and calomel, the purgative powers of which it alfo reciprocally augments; fo that a compound, formed of fmall portions of rhubarb and a neutral falt or calomel, acts with more certainty, and quicker, than large dofes of either feparately taken. Rhubarb is particularly adapted for the greater number of cafes of diarrhœa, as it evacuates any acrid matter that may be offending the bowels, before it acts as an aftringent. As a ftomachic and aftringent, it is ufefully given in dyfpepfia, hypochondriafis, and in a weakened relaxed ftate of the bowels, combined with ginger, nutmeg, foda, or bitters. Externally its powder is fometimes fprinkled over ulcers, to affift their granulation and healing.

Its officinal preparations are as follow: *viz. Infufum rhei,* Lond. Pharm., infufion of rhubarb, prepared by macerating for two hours a drachm of rhubarb root, fliced, with half a pint of boiling water, in a lightly covered veffel, and ftraining it.

Infufum rhei palmati, Edinb. Pharm., infufion of rhubarb, prepared by macerating half an ounce of bruifed rhubarb root with eight ounces of boiling water, in a covered veffel, for twelve hours, and then adding one ounce of fpirit of cinnamon, and ftraining it. Thefe infufions differ chiefly in their ftrength; but that of the Edinburgh difpenfatory is rendered pleafanter by the addition of the fpirit. The colour of both is a reddifh-brown, much deepened by the addition of alkalies. The following fubftances either occafion precipitation,

precipitation, or alter the properties of this infusion, and are therefore incompatible in formulæ with it: *viz.* the strong acids and lime-water, solution of sulphate of iron, sulphate of zinc, nitrate of silver, oxymuriate of mercury, superacetate of lead, and tartarized antimony; infusions of catechu, cinchona, and cusparia.

These infusions are the best form in which rhubarb can be given, when they are intended for acting on the bowels. The dose of the former may be from f℥j to f℥iv, and of the latter half the quantity, united with neutral salts or aromatics, as circumstances may direct.

Extractum rhei, Lond. Pharm., extract of rhubarb, is obtained by macerating for four days, in a gentle heat, a pound of bruised rhubarb root, with a pint of proof spirit, and seven pints of water; then straining the solution, and setting it apart that the feculencies may subside. Pour off the clear liquor, and evaporate it to a proper consistence. The virtues of rhubarb are impaired during this process of inspissation, and the simple infusion is preferable. The dose is from grs. x to ʒß, given in the form of pills, or dissolved in peppermint water.

Tinctura rhei, Lond., tincture of rhubarb, is prepared by macerating for fourteen days two ounces of rhubarb root sliced, half an ounce of cardamom seeds bruised, two drachms of saffron, in two pints of proof spirit, and filtering. The Dublin pharmacopeia directs to take of rhubarb root sliced, two ounces; lesser cardamom seeds husked and bruised, and liquorice bruised, of each half an ounce; saffron, two drachms; and proof spirit, two pints: to digest for seven days, and then filter.

Tincture rhei palmati, Edinb., tincture of rhubarb, is prepared by digesting for seven days three ounces of rhubarb root sliced, half an ounce of lesser cardamom seeds bruised, in two pounds and a half of proof spirit, and filtering through paper.

Tinctura rhei composita, Lond., compound tincture of rhubarb, is prepared by macerating for fourteen days two ounces of rhubarb root sliced, half an ounce of liquorice root bruised, ginger root sliced, and saffron, of each two drachms, in a pint of water, and twelve fluid ounces of proof spirit, and then filtering.

Tinctura rhei et aloes, tincture of rhubarb and aloes, formerly *elixir sacrum*, or sacred elixir, Edinb., is prepared by digesting for seven days ten drachms of rhubarb root sliced, six drachms of soccotorine aloes powdered, half an ounce of lesser cardamom seeds bruised, in two pounds and a half of proof spirit, and filtering through paper.

Tinctura rhei et gentianæ, tincture of rhubarb and gentian, Edinb., formerly *tinctura rhei amara*, or bitter tincture of rhubarb, is obtained by digesting for seven days two ounces of rhubarb root sliced, half an ounce of gentian root sliced, in two pounds and a half of proof spirit, and filtering through paper.

All these tinctures of rhubarb are purgative and stomachic; but they are not generally used in the first intention, on account of the strength of the menstruum, and are therefore more usually employed as adjuncts to saline purgatives, for giving them warmth, and to stomachic infusions in dyspepsia, flatulent colic, diarrhœa, the costiveness of old people, and of cold phlegmatic habits. The dose for operating as a purgative is fʒvj, and from fʒj to fʒiij for producing their stomachic effects.

Pilulæ rhei compositæ, Edinb., compound rhubarb pills. See PILLS.

Vinum rhei palmati, Edinb., wine of rhubarb, is prepared by macerating for seven days two ounces of rhubarb root sliced, a drachm of canella bark bruised, in two ounces of proof spirit, and fifteen ounces of Spanish white wine, and filtering through paper. This wine, when newly prepared, has the same properties, and may be applied to the same uses, as the tincture; but it is liable to undergo decomposition. The dose is from f℥ß to f℥j, or more. Rhubarb is also an ingredient in a variety of compositions. Woodv. Med. Bot. Thomson's Lond. Disp.

The Indian rhubarb sown in our gardens has this peculiar property, that it yields a fine and clear gum. This is perfectly white and pellucid, and in the months of June and July is so plentiful, that an ounce may sometimes be gathered at a time from one plant of it. It exudates of itself from all parts of the stalks and ribs of the leaves, and sometimes from the under part of the leaves themselves. It stands in some places in large drops, and in others the stalks, &c. seem only to be covered with a thin layer of it; and the under part of the leaves in some have it in form of twisted wires or long icicles. The plant may always be seen wounded by a sort of caustic in the places where the germen makes its way out, and these may be followed with any pointed instrument through the skin. In some parts of the plant this juice is found to be turned gummy within it, and looks like clear ice. As this is the only known herbaceous plant that yields a true gum like that of trees, it would be worthy of observation, whether or not some of our own plants have some tendency of nature to form a juice of the same kind. It would be most proper to look for this in the plants of the same genus, and as nearly related to the rhubarb as we can. The docks, so common about our fields, are of the same genus; and the sorrel shews, by its taste, that it is particularly allied to the plant; for both are alike of the dock kind, and both alike sour. It would be proper to look carefully about the leaves of sorrel a little before it flowers, to see whether any thing like the same gum appears on it.

There is yet this farther analogy between this rhubarb and our common sorrel; that the husks of our sorrel, boiled in water, with a little alum, turn it to a fine red colour; and the husks of rhubarb do the same, and both the one and the other often turn red in decaying.

The juice of the roots of this rhubarb, extracted by bruising and steeping it in common water, when the liquor is strained and evaporated, becomes only a clear uninflammable gum, and melts in the flame of a candle. This gum, as well as that of the stalks and leaves, is of an insipid taste; and it is observable, that though the plant naturally yields it in so large a quantity, yet it will not flow from wounds made by art in any part of the plant. Upon the consideration of the insipid taste of this gum, and its solubility in water, we may found some probable conjecture, in regard to the different virtues of this plant in purging and binding.

The woody fibres have a strong taste; and, in all probability, are alone endued with the astringent quality. An infusion of rhubarb is said to purge, and a powder of it to bind: the reason is easily seen on this consideration. The water in infusion takes up all this gummy juice, and its other juices, but leaves the fibrose part behind, in consequence of which, it ought to purge without binding; but in case of giving the powder, the juices are in great part evaporated in the drying, and the woody part left almost alone; it therefore purges but little, and proves powerfully astringent. Phil. Trans. N° 224.

RHUBARB, in *Agriculture*, a plant of the thick, fleshy, tap-rooted, perennial kind, that may in some cases be probably cultivated in the field with advantage. There are two sorts, the *common*, and the *palmated* or true kind. In the first the root strikes to a great depth, and is thick and branching, having

having roundiſh ſmooth heart-ſhaped leaves, and an upright ſtrong ſtem, three feet in height; while, in the latter, the root is thick and fleſhy, and the leaves large and palmated, having the ſtem five, ſix, or more feet in height. Beſides the uſe of the roots as a drug, parts of the young ſtalks of the plants, as well as of the leaves, may be made uſe of, when cut, peeled, and prepared in the ſpring ſeaſon, as an article of food.

This plant is uſually raiſed by ſowing the well ripened ſeed in the autumn or early ſpring ſeaſons, as about September, or in February, on beds of rich, deep, well-manured earth, either in the drill or broadcaſt manner: the plants being afterwards kept clean from weeds, and properly thinned. But the autumn is ſaid to be the better, as the plants are more ſtrong for planting in the ſpring. When the plants have attained four or five inches in growth, they ſhould be planted out on hills, made at the diſtance of four feet, by digging out the earth to the depth of three feet, and filling in with well-rotten manure, and the mould taken out, ſo as to raiſe the plants a little above the natural ſurface of the land. Some, however, direct that a deep, rich, well prepared ſoil, that is neither too moiſt nor too dry, ſhould be choſen for this ſort of culture, the ſeeds being ſown upon it in the early autumn, ſo as to remain without tranſplanting, as by this means the plants ſuffer no check in their growth, and the roots become larger and more fair. The plants, in both modes, muſt be conſtantly kept clean and free from all ſorts of weeds, and in the latter they ſhould be ſet out in the different hoeings to the diſtance of ſix or eight inches at firſt, and afterwards to two or three feet, or more. When the leaves and ſtems decay in the autumn, the ground ſhould be well cleaned; and in the ſpring, on the plants protruding, be dug well, or hoed between them. In the third year the roots will, in moſt caſes, be in a ſtate to be taken up for uſe.

Another method has been ſuggeſted for raiſing theſe plants, as being more eaſy, ſecure, and expeditious, which is by planting the off-ſets, eyes, or buds, ſeparated from the upper parts of the roots, with a ſmall proportion of the old root, having ſome root fibres to them; theſe may be taken from the old roots of three or four years' growth. In this way a year is ſaved, and the plants leſs expoſed to danger from ſlugs, as well as more certain in growing, leſs tender, and the ſize of the roots equal. In Mr. Hayward's practice in this mode, the off-ſets were ſlipped from the heads of large plants in the ſpring, and ſet, by means of a dibble, at the diſtance of about a foot. And on further experience, when he took up his roots in the ſpring or autumn, he divided the head into many parts, which he planted directly at two feet diſtance, where intended for further removal, but if to remain for a crop, at four feet and a half.

It may be noticed, that in the culture of this root, a gentle declivity is the beſt ſituation; it ſhould not be too much ſhaded, either on the ſouth or weſt. But it is eſſential that there be a great depth and richneſs of ſoil, which is beſt when of the light loamy kind, and perfectly free from any ſtagnation of moiſture. Where the ſituation is flat, the land is beſt raiſed into ridges or beds, with deep furrows or trenches between them.

And when the ſeed-ſtems are removed in the autumn, the crowns of the plants ſhould be well covered over with mould, ſo as to form a ſort of hillock, as by this means the moiſture will be more effectually kept from the plants.

But where the tranſplanting method is practiſed, it is adviſed that great care ſhould be taken that the nurſery beds are well watered, and protected from inſects, as the ſtronger the plants are here, the better they ſucceed afterwards. In forming plantations, and filling up vacancies in them, the fineſt and moſt healthy plants are always to be made uſe of. Where the chief bud is deſtroyed, they never anſwer well.

The particular injuries to which theſe young plants are expoſed, are the attacks of ſlugs and inſects, and too much expoſure to froſt in their more early growth; but afterwards they are ſufficiently hardy.

In general the roots are proper for being taken up about the third or fourth year, or as ſoon as the plants have flowered perfectly. And the autumn is the beſt ſeaſon for the purpoſe, when the ſtems decay, when they ſhould be well dried, cleaned, and cut into thin pieces, ſtringing them upon packthread, and hanging them up to dry in a gradual manner.

It has been obſerved by the writer of the Perthſhire Agricultural Report, that it is ſurpriſing the culture of rhubarb has not claimed more attention, and been adopted on a more extenſive ſcale, as it is calculated to bring large profits.

The palmated rhubarb has been cultivated in Suſſex by the earl of Egremont, for medicinal purpoſes, who has it dried and cured in as good order and preſervation as any imported from abroad. It is taken out of the ground in autumn, after ſtanding ſeven or eight years, and then waſhed clean, and dried, either in the ſun, or on the flue of a hot-houſe, after being cut into thin pieces. In uſing it, no difference is found between it and the foreign, and great ſaving might be made in this way in the importation of the article.

Rhubarb, *Monk's*, is a ſpecies of dock. See Rumex.

The root of this plant is more aſtringent than rhubarb, but is much inferior in its purgative virtue, though given, as uſually directed, in double its doſe; nauſeating the ſtomach, without producing any conſiderable evacuation. It communicates a deep yellow tincture, both to water and ſpirit. Lewis.

Rhubarb, *White*. See Mechoacan.

RHUBRA, in *Ancient Geography*, a town ſituated on the ſouthern coaſt of the iſland of Corſica, between the port of Syracuſe and the promontory Graniacum. Ptolemy.

RHUBRICATA, a town of Hiſpania, in the Tarragoneſe, in the country of the Lacetanians. Ptolemy.

RHUBUNA, a town of Africa, on the northern bank of the river Gira, between Artagira and Lynxama. Ptolemy.

RHUDA, a town of Aſia, in Parthia, between Paſacarta and Simpſimida. Ptolemy.

RHUDDLAN, or Rhyddlan, in *Geography*, a borough town in the cwmwd of Rhuddlan, cantref of Tegeing (now called the hundred of Rhuddlan), county of Flint, North Wales, is ſituated on the eaſtern bank of the river Clwyd, at the diſtance of five miles N. from the city of St. Aſaph, and 215 miles N.W. from London. It is a town of great antiquity, and, as appears from tradition, and likewiſe from the remains of its caſtle, was a place of conſiderable importance in early times. A large common in the immediate vicinity was the theatre of a dreadful battle fought between the Welſh, under prince Caradoc, and the Saxons, commanded by Offa, king of Mercia. In this action the Welſh were defeated, and their leader ſlain; and to add to their misfortunes, Offa put to death all the men and children who fell into his hands, but ſpared the women. The memory of the above tragical occurrence is commemorated in a ballad called "Morfa Rhuddlan," the air of which is characteriſed by Pennant as being "moſt tenderly plaintive." This town was conſtituted a free borough by king

Edward I., who held a parliament here in 1284, when the ſtatute of Rhuddlan was paſſed. At a private houſe is ſtill ſhewn a "Gothic window," which is ſaid to have been part of the building uſed on the occaſion of theſe parliamentary meetings. Another houſe is alſo pointed out as having been honoured by the reſidence of the monarch himſelf during his ſtay at Rhuddlan, but it is more likely that he occupied the caſtle; and certain it is, that queen Eleanor's accouchment of a daughter occurred there in 1283. A copy of the roll of the king's expences, while at Rhuddlan, is printed in the Archæologia, and exhibits ſeveral intereſting and curious particulars relative to the prices of proviſions and labour at that early period. Rhuddlan caſtle is built of a reddiſh free-ſtone, and is nearly ſquare in form. At two of the oppoſing corners were formerly two towers, though the other corners had only one each. Of theſe, the three on the northweſt ſide of the fortreſs are tolerably entire, but the remainder is much dilapidated. By whom this caſtle was originally built is uncertain; ſome writers attributing it to Llewellin-ap-Sitſyllt, about the commencement of the 11th century, and others to Robert de Rodelent, who lived towards the cloſe of the ſame century. Be this as it may, however, it was deſtroyed by Gruffydd-ap-Crinan in the reign of Henry II., and was ſubſequently re-erected and fortified by that monarch. In 1399 it was ſeized and garriſoned by the earl of Northumberland, previous to the depoſition of the unfortunate king Richard II., who dined here on his way to Flint caſtle. During the civil wars between king Charles I. and his parliament, Rhuddlan caſtle was at firſt occupied by the royaliſts, but, after a ſhort ſiege, the garriſon were forced to ſurrender to the parliamentary troops, commanded by general Mytton. This event happened in July 1646, and in the following December, the fortreſs was diſmantled by order of parliament. It was ſurrounded by a deep ditch, and had an additional one on the north ſide: both of theſe ditches are ſtill remaining. The walls are very ſtrong, and well calculated for defence. South from the caſtle is a fortification, commonly ſuppoſed to have been conſtructed by the parliamentary troops as a battery during the ſiege above-mentioned; but though it may have been uſed for that purpoſe, it is doubtleſs of much higher antiquity. Near this ſpot formerly ſtood a houſe of Black friars, which muſt have been founded previous to 1268, as it is recorded, that in that year, Anian de Schonan, one of its priors, was made biſhop of St. Aſaph. It ſuffered greatly in the wars between king Edward I., and prince Llewellin ab Gruffydd; but it recovered and ſubſiſted till the reign of Henry VIII. when it was diſſolved, and its buildings granted to Henry ap Harry. Tanner ſtates that there was another religious houſe in the immediate vicinity of Rhuddlan, as old as the year 1281, but no traces of its ſcite can now be diſcovered.

Edward I., in his charter conſtituting Rhuddlan a borough, appointed the conſtable of the caſtle mayor, and ordered that two bailiffs ſhould be choſen annually, as his aſſiſtants, from among the burgeſſes. Since the time of Oliver Cromwell, there having been no conſtable, there has conſequently been no mayor, ſo that the bailiffs are now the chief officers of the town. The burgeſſes contribute towards the new election of a repreſentative in parliament for the borough of Flint. The voters muſt either inhabit the town itſelf, or that part of the pariſh called Rhuddlan Franchiſe, which extends to the diſtance of a mile. At preſent no regular market is held here, but there are fairs for cattle on the 2d of February, 25th of March, and the 8th of September. The pariſh, according to the parliamentary returns of 1811, contains 131 houſes, and 831 inhabitants.

The river Clwyd, upon which Rhuddlan is ſituated, is only navigable for veſſels of about twenty tons burden as high up as the town; but about two miles below it is a port, into which veſſels of conſiderable magnitude can enter and remain with ſecurity. Carliſle's Topographical Dictionary of Wales, 4to. 1813. Pennant's Tour in Wales, 1770, Lond. 2 vols. 4to. 1778.

RHUDEN, or Ruthen, a town of Germany, in the duchy of Weſtphalia; 64 miles E. of Duſſeldorp.

RHUDIANA, in *Ancient Geography*, a country of Aſia, in Carmania. Ptolemy.

RHULA, in *Geography*, a town of Saxony, in the principality of Eiſenach, famous for its manufacture of knives; four miles S.S.E. of Eiſenach.

RHUMB, Rumb, or *Rum*, in *Navigation*, a vertical circle of any given place; or the interſection of a part of ſuch a circle with the horizon.

Rhumbs, therefore, coincide with *points* of the world, or of the horizon.

And hence the mariners diſtinguiſh the rhumbs by the ſame names as the points and winds. But we may obſerve, that the rhumbs are denominated from the points of the compaſs in a different manner from the winds: thus, at ſea, the north-eaſt wind is that which blows from the north-eaſt point of the horizon towards the ſhip in which we are; but we are ſaid to ſail upon the north-eaſt rhumb, when we go towards the north-eaſt.

They uſually reckon 32 rhumbs, which are repreſented by the 32 lines in the roſe, or card, of the compaſs.

Aubin defines a rhumb to be a line on the terreſtrial globe, ſea-compaſs, or ſea-chart, repreſenting one of the 32 winds which ſerve to conduct a veſſel. So that the rhumb a veſſel purſues is conceived as its route, or courſe.

Rhumbs are divided and ſubdivided like points. Thus, the whole rhumb anſwers to the cardinal point. The half rhumb to a collateral point, or makes an angle of 45° with the former. The quarter rhumb makes an angle of 22° 30′ with it. And the half-quarter rhumb makes an angle of 11° 15′.

Sometimes navigators divide the 32 points into four quarters, and call the rhumb next the eaſt the firſt rhumb, the next to that the ſecond rhumb, &c.

For a table of the rhumbs, or points, and their diſtances from the meridian, ſee Wind.

Rhumb-*Line*, *Loxodromia*, is a line prolonged from any point of the compaſs in a nautical chart, except the four cardinal points; or it is the line which a ſhip, keeping in the ſame collateral point, or rhumb, deſcribes throughout its whole courſe. See Loxodromy.

The great property of the rhumb-line, or loxodromia, and that from which ſome authors define it, is, that it cuts all the meridians under the ſame angle.

This angle is called the *angle of the rhumb*, or the loxodromic angle.

The angle which the rhumb-line makes with any parallel to the equator, is called the *complement of the rhumb*.

An idea of the origin and properties of the rhumb-line, the great foundation of navigation, may be conceived thus: a veſſel beginning its courſe, the wind with which it is driven makes a certain angle with the meridian of the place; and as it is ſuppoſed, the veſſel runs exactly in the direction of the wind, it makes the ſame angle with the meridian which the wind makes.

Suppoſing then the wind to continue the ſame, as each point

point or inſtant of the progreſs may be eſteemed the beginning, the veſſel always makes the ſame angle with the meridian of the place where it is each moment, or in each point of its courſe, which the wind makes.

Now a wind, *e. gr.* that is north-eaſt, and which, of conſequence, makes an angle of 45° with the meridian, is equally north-eaſt, wherever it blows, and makes the ſame angle of 45° with all the meridians it meets. A veſſel, therefore, driven by the ſame wind, always makes the ſame angle with all the meridians it meets with on the ſurface of the earth.

If the veſſel ſail north and ſouth, it makes an angle infinitely acute with the meridian, *i. e.* it is parallel to it; or rather ſails in it. If it run eaſt and weſt, it cuts all the meridians at right angles.

In the firſt caſe, it deſcribes a great circle; in the ſecond, either a great circle, *viz.* the equator, or parallel to it. If its courſe be between the two, it does not then deſcribe a circle; ſince a circle, drawn in ſuch a manner, would cut all the meridians at unequal angles, which the veſſel cannot do.

It deſcribes, therefore, another curve, the eſſential property of which is, that it cuts all the meridians under the ſame angle. This curve is what we call the *loxodromic curve, rhumb-line,* or *loxodromy.*

It is a kind of ſpiral, which, like the logarithmic ſpiral, makes an infinity of circumvolutions without ever arriving at a certain point, to which it yet ſtill tends, and towards which it approaches at every ſtep.

This aſymptotic point of the rhumb-line is the pole: at which, were it poſſible for it to arrive, it would find all the meridians conjoined, and be loſt in them.

The courſe of a veſſel then, except in the two firſt caſes, is always a rhumb-line; which line is the hypothenuſe of a right-angled-triangle, whoſe two other ſides are the ſhip's way or diſtance run in longitude and latitude. Now, the latitude is uſually had by obſervation, and the angle of the rhumb, with one or other of the two ſides, by the compaſs. See LATITUDE, and COMPASS.

All, therefore, that is required by calculation in ſailing, is the value of the length of the rhumb-line, or the diſtance run.

But as ſuch curve line would prove very perplexing in the calculation, it was neceſſary to have the ſhip's way in a right line; which right line, however, muſt have the eſſential porperty of the curve line, *viz.* to cut all the meridians at right angles. See CHART.

If P A, P F, P G, &c. (*Plate* II. *Navigation, fig.* 5.) be ſuppoſed meridians, A I the equator, and E B, K L, M N, parallels; A O will repreſent a rhumb-line, which makes equal angles with the meridians, and conſequently different from thoſe made by a great circle, which cuts the meridians at unequal angles; whence it follows that the rhumb is not a great circle of the ſphere. If a ſhip, therefore, be at firſt directed towards E, and conſtantly perſiſt in the ſame rhumb, it will never arrive at the place E, but at the place O, which is farther from the equator A I.

Hence, as on the ſurface of a ſphere the ſhorteſt way between A and O is an arc of a great circle between A and O; the rhumb-line is not the ſhorteſt way, or leaſt diſtance from one place to another.

RHUMB-*Lines, Uſe of the.* 1. If the meridians P A, P B, P C, P D, &c. (*fig.* 6.) be not very far apart, the rhumb-line A I H G is divided by the equidiſtant parallels L E, M F, N G, &c. into equal parts.

Hence, 1. The parts of the rhumb A I and A G are as the latitudes A L and A N of the places A and G. 2. Since the arcs A B, I K, H F, are equal in magnitude, and therefore unequal in number of degrees; the ſum of the arcs, called the *latus mecodynamicum,* or *miles of longitude,* is not equal to the difference of longitude A D of the places A and G.

2. The length of the rhumb-line A G is to the change or difference of latitude G D, in the ſame ratio as the whole ſine to the co-ſine of the angle of the rhumb.

Hence, 1. The rhumb ſailed on being given, together with the difference or change of latitude, turned into miles, the length of the rhumb-line, or the diſtance from the place A to the place G upon the ſame rhumb, is had by the rule of three. 2. The rhumb being given, together with the quantity of the ſhip's way on the ſame rhumb, *i. e.* the length of the rhumb A G; the difference of latitude D G is had, by the rule of three, in miles, to be converted into degrees of a great circle. 3. The difference of latitude D G being given in miles, as alſo the length of the rhumb-line A G, the angle of the rhumb, and conſequently the rhumb ſailed on, is had by the rule of three. 4. Since the co-ſine of an angle is to the whole ſine, as the whole ſine to the ſecant of the ſame angle; the difference of latitude G D is to the length of the rhumb-line A G, as the whole ſine to the ſecant of the angle of the rhumb.

3. The length of the rhumb-line, or of the ſhip's way in the ſame rhumb, A G, is to the latus mecodynamicum or mecodymanic ſide A B + I K + H F, as the whole ſine to the ſine of the loxodromic angle G A P.

Hence, 1. The rhumb, or angle of the rhumb, being given; as alſo the ſhip's way in the ſame rhumb-line A G, the mecodynamic ſide is had, by the rule of three, in miles, *i. e.* in the ſame meaſure in which the length of the rhumb is given. 2. In like manner, the mecodynamic ſide A B + I K + H F being given, as alſo the rhumb-line or ſhip's way A G, the rhumb ſailed is found by the rule of three.

4. The change of latitude G D is to the mecodynamic ſide A B + I K + H F; as the whole ſine to the tangent of the loxodromic angle P A G or A I B.

Hence the rhumb or loxodromic angle P A G, and the change of latitude G D being given, the mecodynamic ſide is found by the rule of three.

5. The mecodynamic ſide A B + I K + H F is a mean proportional between the aggregate of the rhumb A G, and the change of latitude G D, and their difference.

Hence the change of latitude G D, and the rhumb-line A G being given in miles, the mecodynamic ſide is found in the ſame meaſure.

6. The mecodynamic ſide A B + I K + H F being given, to find the longitude A D.

Multiply the change or difference of latitude G D by ſix, which reduces it into parts of ten minutes each; divide the mecodynamic ſide by this product, and the quotient gives the miles of longitude, anſwering to the difference of latitude in ten minutes; reduce theſe miles of longitude in each parallel into differences of longitude from a loxodromic table, and the ſum of theſe is the longitude required.

7. If a ſhip ſail on a north or a ſouth rhumb, it deſcribes a meridian; if on an eaſt or weſt rhumb, it deſcribes either the equinoctial, or a parallel to it. Wolfii Elem. Math. tom. iv. cap. 11.

1. *To find the rhumb between two places by calculation, or geometrically,* we have two canons, or proportions: the firſt, as the radius is to the co-ſine of the middle latitude, ſo is the difference of longitude to the whole departure from the meridian, in the courſe between the two places propoſed.

The fecond, as the radius is to the half fum of the co-fines of both latitudes, or (rather for geometrical fchemes) as the diameter is to the fum of the co-fines of both latitudes, fo is the difference of longitude to the departure from the meridian. For the application of thefe principles, fee SAILING.

RHUN, PULO, in *Geography*. See POOLAROX.

RHUNE, a river which rifes in the New Foreft, and runs into the Seine; two miles N.W. of Nordheim.

RHUS, in *Botany*, an ancient name, ῥοῦς, or ῥοῦς, of the Greeks, generally fuppofed of doubtful etymology. De Theis deduces this, and many fimilar words, which have a reference to a red colour, from the Celtic *rhudd* or *rub*, red. Hence, according to him, we have not only *Rubia*, but *Rofa*. The fruit of the original ῥοῦς of Diofcorides, *Rhus Coriaria*, well juftifies this explanation.—Linn. Gen. 146. Schreb. 197. Willd. Sp. Pl. v. 1. 1477. Mart. Mill. Dict. v. 4. Sm. Prodr. Fl. Græc Sibth. v. 1. 206. Purfh 204. Ait. Hort. Kew. v. 2. 161. Juff. 369. Lamarck Illuftr. t. 207. Gærtn. t. 44.—Clafs and order, *Pentandria Trigynia*. Nat. Ord. *Dumofæ?* Linn. *Terebintaceæ*, Juff.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five deep, erect, permanent fegments. *Cor.* Petals five, ovate, moderately fpreading. *Stam.* Filaments five, very fhort; anthers fmall, fhorter than the corolla. *Pift.* Germen fuperior, roundifh, as large as the corolla; ftyles fcarcely any; ftigmas three, heart-fhaped, fmall. *Peric.* Berry roundifh, of one cell. *Seed* folitary, roundifh, bony.

Obf. Some fpecies have dioecious flowers.

Eff. Ch. Calyx in five deep fegments. Petals five. Berry fuperior, with one feed.

An extenfive fhrubby or arborefcent genus, whofe fpecies are found in North America, Japan, China, the Cape of Good Hope, and a few in the fouth of Europe. Their qualities are of a cauftic nature, in certain inftances highly virulent, whence fome fpecies have acquired the name of Poifon-trees. Others are celebrated for producing valuable refins for varnifh. Willdenow has collected together the characters of thirty-three fpecies; but many of them he had not feen, particularly thofe found by Thunberg at the Cape. The genus is divided into three fections, by the ftructure of the leaves, of which we fhall give a few examples. Purfh has two fpecies not in Willdenow. Twenty-one are cultivated in the Englifh gardens. *Aiton.*

Section 1. *Leaves pinnate.* Thirteen fpecies, to which the two defcribed by Purfh are to be added; fee hereafter.

R. *Coriaria.* Elm-leaved Sumach. Linn. Sp. Pl. 379. Willd. n. 1. Ait. n. 1. Sm. Fl. Græc. Sibth. t. 290, unpublifhed. Woodv. Med. Bot. t. 261. Ger. Em. 1474. (Rhus; Matth. Valgr. v. 1. 195.)—Leaves pinnate; leaflets oval, bluntly ferrated, downy beneath; their common ftalk winged in the upper part.—Native of the Levant. Frequent in our gardens and fhrubberies, ever fince the days of Gerarde, (though lefs common than the American *R. typhinum*,) flowering in July, and retaining its denfe, branched, ample, upright *clufters*, of deep-red, rough, coriaceous *berries*, even till winter, after the leaves are fallen. The tree is of a dwarf bufhy habit, with fpreading, afcending, round, downy branches, of a foft fpongy texture. *Leaves* from eight inches to a foot long, of about five pair of leaflets, with an odd one; paler, downy, and veiny beneath. *Flowers* greenifh, each with a large hoary *germen*, which becomes a globular, crimfon, hairy *berry*, the fize of an Elder-berry. The tafte of this fruit is very acid and aftringent. It has been ufed in Greece, from the moft remote antiquity, for tanning leather; as have alfo the leaves, to the prefent day. Both have likewife been employed in medicine, either for their tonic or cooling qualities, nor do they appear to poffefs any of the dangerous qualities for which fome fpecies of this genus are remarkable. Dr. Woodville's figure of this plant ought to have been quoted in Hort. Kew. as not cited by Willdenow, and being moreover an Englifh publication.

R. *javanicum.* Java Sumach. Linn. Sp. Pl. 380. Willd. n. 3. Ait. n. 3. Thunb. Jap. 121.—Leaves pinnate, ovate, pointed, ferrated; very downy and foft beneath.—Native of Japan, flowering in September. Introduced into the ftoves at Kew, by fir Jofeph Banks, in 1799. The *branches*, and all the *ftalks*, as well as the backs of the *leaves*, are clothed with extremely foft, denfe, velvet-like pubefcence, as is the upper fide of the foliage in fome degree. Each *leaf* has three pair, with an odd one, of ftalked, ovate, taper-pointed leaflets, ftrongly ferrated, and about an inch and a half long. *Flowers* very fmall, in long, flender, lax, fimple, axillary clufters.

R. *glabrum.* Smooth Sumach. Linn. Sp. Pl. 380. Willd. n. 4. Ait. n. 4. Purfh n. 2. Kalm's Travels, v. 1. 66. 75. (R. virginicum, paniculâ fparfâ, ramis patulis glabris; Dill. Elth. 323. t. 243. f. 314.)—Leaves numeroufly pinnate, lanceolate, ferrated, fmooth on both fides; glaucous beneath.—Common in North America, flowering in July and Auguft, nor is it rare in our fhrubberies. Kalm fays that neglected corn-fields are foon overrun with this tree, whofe roots fubfequently render ploughing the ground very difficult. The *leaves* confift of from eight to twelve pair of longifh taper-pointed leaflets, fmooth and naked on both fides. The *fruit* much refembles the firft fpecies in colour and mode of growth, but is lefs hifpid. According to Mr. Purfh, the *R. elegans*, Ait. Hort. Kew. n. 5. Willd. n. 5, is only a variety of this, with dioecious *flowers*, and a more fcarlet-coloured *fruit*.

R. *viridiflorum.* Green-flowered Sumach. Lamarck Dict. v. 7. 504. Purfh n. 3. (R. canadenfe; Mill. Dict. ed. 8. n. 5.)—Leaves numeroufly pinnate, ovato-lanceolate, ferrated; glaucous, and fomewhat downy beneath. Clufters erect.—On the edges of woods in dry funny fituations, in Pennfylvania and Virginia, flowering in July and Auguft. This is one of the fpecies added by Mr. Purfh, after Poiret in Lamarck, but not without a doubt of its being diftinct from the laft. We can find no important difference in a fpecimen from the French gardens, except that the *leaflets* are rather more ovate. The *flowers* are yellowifh-green. *Leaves* not always downy.

R. *pumilum.* Dwarf Poifon Sumach. Michaux Boreal-Amer. v. 1. 182. Purfh n. 4.—Leaves numeroufly pinnate, oval, fcarcely pointed, deeply toothed; downy beneath. Branches and footftalks downy. Fruit clothed with velvet down.—Native of Upper Carolina, flowering in July. The *ftem* is not above a foot high. This fpecies is unknown in our gardens. Mr. I. Lyon, who gathered it, affured Mr. Purfh, that it was the moft poifonous of the genus, he having been "poifoned all over his body, and lamed for a confiderable time," in confequence of collecting the feed.

R. *Vernix.* Varnifh Sumach. Linn. Sp. Pl. 380. Willd. n. 6. Ait. n. 6. Purfh n. 5. Kalm's Travels, v. 1. 68. 77. (Toxicodendron, foliis alatis, fructu rhomboide; Dill. Elth. 390. t. 292. f. 377.)—Leaves pinnate, very fmooth, as well as the branches; leaflets elliptical, entire, fomewhat abrupt, pointed. Clufters compound, lax. Flowers dioecious. Fruit polifhed.—Found in low copfes, from Canada to Carolina, flowering in July. *Purfh.* It has been in our

our gardens for a century paſt, but is not common. Kalm ſpeaks of its dangerous effects, to various perſons, whoſe ſkin, and whole body, in ſome caſes, are affected with inflammation, ſwelling and pain, in conſequence of their touching any part of this tree, or expoſing themſelves to its effluvia; whilſt others, even of the ſame family, can cut or handle it with impunity. Kalm himſelf was generally unhurt by this poiſon, but on one occaſion he did not entirely eſcape its effects. The whole *tree* is very ſmooth. *Leaflets* about ſix pair with an odd one. *Berries* the ſize of a pea, white and remarkably poliſhed, both in a freſh and dry ſtate. Miller contended that this was the ſame with the true Varniſh-tree of Japan, deſcribed in Kæmpfer's Am. Exot. 791. t. 792; which opinion was combatted by Ellis, in the Philoſophical Tranſactions, n. 112. We believe the latter to be in the right. The two trees, indeed, ſeem very nearly akin, but the *leaflets* in Kæmpfer's plate are broader than thoſe of the American plant, nor does his deſcription of the fruit exactly anſwer. Yet Thunberg calls the Japaneſe plant *Rhus Vernix*. Nothing ſeems to be known in America, as to the tree in queſtion affording any varniſh, though that point is certainly worth enquiry, conſidering its near relationſhip, at leaſt, to one whoſe produce is ſo valuable. Kæmpfer ſpeaks of the poiſonous effects of the effluvia of his varniſh-tree, like what we have related of the other.

Section 2. *Leaves ternate or quinate.* Eighteen ſpecies.

R. *Toxicodendron.* Trailing Poiſon-oak, or Sumach. Linn. Sp. Pl. 381. Willd. n. 17. Ait. n. 11. Purſh n. 7. (Edera trifolia canadenſis; Cornut. Canad. 96. t. 97. Barrel. Ic. t. 228.) *β*. R. radicans; Linn. Sp. Pl. 381. Willd. n. 16. Ait. n. 10. Kalm's Travels, v. 1. 67. 177. (Toxicodendron triphyllum glabrum; Duham. Arb. v. 2. 341. t. 98.)—Leaves ternate; leaflets ſtalked, ovate, angular, cut, or crenate. Stem creeping.—Common in woods, fields, and hedges, from Canada to Georgia, flowering in June and July. *Purſh.* We readily concur with Mr. Purſh, in conſidering theſe two Linnæan ſpecies as mere varieties. The *leaves* when young are more downy beneath, in ſome inſtances than in others; but that character, as well as their notches, is certainly variable. We ſpeak with confidence on this ſubject, having been at no ſmall trouble formerly, to determine which was the plant recommended in paralytic and rheumatic complaints, by ſome eminent phyſicians in England and France; and after much examination, finding no certain or permanent difference between the two. Kalm ſpeaks of the poiſonous qualities of the preſent ſpecies, as like thoſe of *R. Vernix*; but it had no effect on him, even when he made the raſh experiment of dropping the juice into his eye. The *ſtem* never grows erect, but when it meets with ſupport, will climb, like ivy, to the tops of the loftieſt trees. The *leaflets* are of a broad, ovate, or rhomboidal form, pointed, always more or leſs downy, at leaſt about the ribs, and ſometimes quite covered with ſoft down at the back; their margin occaſionally almoſt entire, but moſt generally, in the downy variety, ſtrongly crenate, cut, or lobed. *Flowers* in compound axillary cluſters, greeniſh, dioecious. *Berries* white. Both varieties have long been known in our gardens, but have nothing to recommend them to general culture, even were they unexceptionable as to danger.

R. *tomentoſum.* Woolly-leaved Cape Sumach. Linn. Sp. Pl. 382. Willd. n. 24. Ait. n. 15. (Vitex trifolia minor indica ferrata; Commel. Hort. v. 1. 179. t. 92.)—Leaves ternate; leaflets ſtalked, rhomboid, ſomewhat angular; white and very downy beneath.—Native of the Cape of Good Hope. It was introduced very early by the Dutch, into the European gardens, but we know not whether it has been preſerved, or noticed, though an extremely handſome evergreen ſhrub, the backs of whoſe *leaves* are elegantly white and downy, with reddiſh veins. We know nothing of the *flowers* or *fruit*. Commelin miſtook this plant for the Eaſt Indian *Vitex trifolia*.

Several other three-leaved ſpecies of *Rhus*, from the Cape, elegant evergreen ſhining-leaved ſhrubs, are cultivated in our more curious collections, as may be ſeen in Aiton. We ſubjoin one ſpecies to this ſection, which Willdenow has not admitted here.

R. *pentaphyllum.* Five-leaved Morocco Sumach. Deſfont. Atlant. v. 1. 267. t. 77. (Rhamnus pentaphyllus; Jacq. Obſ. faſc. 2. 17. Linn. Syſt. Veg. ed. 14. 233. R. ſiculus; Syſt. Nat. ed. 12. v. 3. 229. R. ſiculus pentaphyllos; Bocc. Sic. 43. t. 21.)—Leaves ternate or quinate; leaflets linear-lanceolate, dilated upwards, obtuſe, nearly ſmooth; cut or undivided. Stem thorny.—Native of uncultivated hills in Morocco and Sicily. A thorny *ſhrub*, or ſmall *tree*, with numerous, round, ſmooth, grey *branches*. *Leaves* alternate, ſtalked, digitate, of from three to five narrow-wedge-ſhaped, obtuſe *leaflets*, above an inch long; ſomewhat downy when young; either quite entire, or unequally toothed, ſometimes pinnatifid. *Flowers* pale yellow, in axillary compound cluſters, dioecious. *Berry* red, reſembling hawthorn, but with three tubercles at the top; its flavour ſlightly acid, not unpleaſant. The *bark* is uſed for tanning, and for dyeing red. *Deſfont.*

Section 3. *Leaves ſimple.* Two ſpecies.

R. *Cotinus.* Venice Sumach, or Coccygria. Linn. Sp. Pl. 383. Willd. n. 32. Ait. n. 21. Jacq. Auſtr. t. 210, Coggygria Theophraſti, and Cotinus coriarius Plinii; Ger. Em. 1476. Cotinus; Duham. Arb. v. 1. t. 78.)—Leaves ſimple, obovate, or orbicular.—Native of Auſtria, Switzerland, Italy, and Greece, in hilly ſituations. Common with us in plantations, for the ſake of the very ſingular and ornamental appearance of its elongated feathery fruit-ſtalks. The *ſtem* is buſhy, the height of a man. *Leaves* ſmooth, orbicular, entire. *Flowers* greeniſh, ſmall, in terminal compound panicles. *Fruit* gibbous. The *leaves* and *ſtalks*, when bruiſed, have an aromatic but pungent and acid ſcent. The whole plant is uſed for tanning in Italy, and called *Scotino*; ſee Smith's Tour. The wood is much uſed by the modern Athenians, according to Dr. Sibthorp, for dyeing wool of a moſt beautiful and rich yellow.

R. *atrum.* Black Sumach. Forſt. Prodr. 23. Willd. n. 33.—"Leaves ſimple, ovate-oblong. Flowers polygamous."—Found by Forſter in New Caledonia. A *ſhrub* or *tree*. We know nothing more of this ſpecies, the only one, except *Cotinus*, with ſimple *leaves*.

Rhus, in *Gardening*, contains plants of the tree and ſhrub kinds, ſumach and toxicodendron; of which the ſpecies cultivated are, the elm-leaved ſumach (R. coriaria); the ſtag's-horn Virginian ſumach (R. typhinum); the ſcarlet ſumach (R. glabrum); the Carolina ſumach (R. elegans); the lentiſcus-leaved ſumach (R. copallinum); the Venice ſumach (R. cotinus); the trailing poiſon-oak, or ſumach (R. toxicodendron); the varniſh ſumach (R. vernix); the rooting poiſon-oak, or ſumach (R. radicans); the woolly-leaved ſumach (R. tomentoſum); the narrow-leaved ſumach (R. anguſtifolium); and the ſhining-leaved ſumach (R. lucidum).

The branches in the firſt ſort are uſed inſtead of oak bark for tanning leather, and it is ſaid that Turkey leather is all tanned with this ſhrub.

In the third ſort there are ſeveral varieties; as the New England ſumach, in which the ſtem is ſtronger, and riſes higher than that of the ſecond ſort; the branches ſpread more horizontally, they are not quite ſo downy, and the

down

down is of a brownifh colour; the leaves are compofed of many more pairs of leaflets, and are fmooth on both fides: the flowers are difpofed in loofe panicles, and are of an herbaceous colour. The Canada fmooth red fumach, which has fmooth branches of a purple colour, covered with a grey pounce; the leaves are compofed of feven or eight pairs of leaflets, which are four inches and a half long, and one inch broad in the middle, terminating in acute points, and a little ferrate, of a lucid green on their upper furface, but hoary on their under, and fmooth: panicle large, compofed of feveral fmaller, each on feparate footftalks, the whole covered with a grey pounce; the flowers are of a deep red colour.

In the fixth fort the root is ufed for dyeing: the leaves and young branches dye black; and the bark is ufed for tanning leather.

In the eighth fpecies Martyn fays, that the milky juice ftains linen a dark brown. The whole fhrub is, in a high degree, poifonous; and the poifon is communicated by touching or fmelling any part of it.

The ninth fpecies having, in common with ivy, the quality of not rifing without the fupport of a wall, tree, or hedge, it is called in fome parts of America creeping ivy. It will climb to the top of high trees in woods, the branches every where throwing out fibres that penetrate the trunk. When the ftem is cut, it emits a pale brown fap of a difagreeable fcent, and fo fharp, that letters or marks made upon linen with it cannot be got out again, but grow blacker the more it is wafhed. Like rhus vernix it is poifonous to fome perfons, but in a lefs degree. Kalm relates, that of two fifters, one could manage the tree without being affected by its venom, whilft the other felt its exhalations as foon as fhe came within a yard of it, or even when fhe ftood to leeward of it, at a greater diftance; that it had not the leaft effect upon him, though he had made many experiments upon himfelf, and once the juice fquirted into his eye; but that on another perfon's hand, which he had covered very thick with it, the fkin, a few hours after, became as hard as a piece of tanned leather, and peeled off afterwards in fcales.

There is a variety with a ftraight and ftout trunk, having a brownifh afh-coloured bark: the leaves fmooth, veined, bright green above, fomewhat paler underneath, pendulous, and fomewhat bent back: in the male plant the leaves are rather wider and longer, and are drawn more to a point; in the female they are fhorter and blunter, and the petioles are reddifh, whereas in the others they are green: the flowers axillary, in racemes; the males larger, whitifh-yellow; the females fmaller, herbaceous, on the germ inftead of the ftyle there are two, fometimes three black dots: fruits round, the fize and form of coriander feeds, ftreaked with five lines, remaining on the tree till new flowers come out; when the outer rind comes off, and a cretaceous fubftance comes into view, in which an afh-coloured, hard, horny feed is involved, flightly divided on the upper part, and fomewhat kidney-fhaped.

Method of Culture.—The firft nine forts of thefe plants are capable of being raifed by feeds and layers, and fome of them alfo by fuckers, or their rooting branches. In the firft method fuch of them as do not fend up fuckers fhould have the feed procured from abroad, and fown in pots of a large fize, or in beds of light mould, being covered in about the depth of half an inch in the autumn. Thofe in pots fhould be protected from the frofts during the winter, and if plunged in a moderate hot-bed in the early fpring, they will be rendered more forward, letting the plants have a free air when they appear. Thofe in the open ground often remain long before they vegetate; they fhould be kept free from weeds, be well watered in fummer, and have the protection of mats the firft winter. When the plants have had the growth of a year or two, they may be planted out in nurfery-rows till fit to be fet out in the places where they are to remain. The potted plants fhould have the protection of the frame the fecond winter, air being freely admitted in mild weather; and in the fpring following they may be fhaken out of the pots without injuring the roots, and be fet out in nurfery-rows, three feet apart, and a foot diftant in the rows, where they may remain two years, and then be planted out where they are to remain.

Such forts as have young branches fufficiently low, may have them laid down in the flit method; when they will moftly have ftricken root in the courfe of a year, and may be taken off and planted out where they are to remain, or in the nurfery.

And all thofe forts that fend up fuckers from the roots fhould have them taken up during the winter, and planted out in nurfery rows, in the manner of the feedlings, till of a proper growth to be planted out.

The feventh and ninth forts may likewife be increafed by their trailing branches, which have ftricken root as they reft on the ground, which fhould be taken up with their roots entire in the autumn, winter, or in early fpring, and be planted out, either where they are to remain, or in nurfery rows, till of fufficient growth for the purpofe they are intended.

The firft and fourth forts, being the moft tender, require the moft fheltered fituations.

Moft of thefe plants afford a milky juice, which is extremely acrid and corrofive.

The three laft forts may be raifed by cuttings and layers with great facility. In the firft method, the cuttings of the young fhoots fhould be planted out in pots of light frefh mould, in the fpring and early fummer months, plunging them in a moderate hot-bed, where they readily ftrike root, being occafionallly watered and fhaded: and when they have formed good roots, they may be potted off into feparate pots. And in the latter mode, any of the young wood may be laid down in the ufual manner, in the early fpring, when by the autumn they will moftly have ftricken good root, and may be taken off, and be potted out the fame way as the cuttings.

All the firft nine forts have a fine effect in mixture with other deciduous fhrubby plants, in the borders, clumps, and other parts of pleafure grounds, and the three laft afford variety among other potted greenhoufe plants of the lefs tender kinds.

Rhus *Cobbe*, in *Botany*. See Schmidelia.

Rhus, in the *Materia Medica*. This genus comprehends a variety of fpecies, which are known to be poifonous; but the *rhus coriaria*, or elm-leaved fumach, is perfectly innocent, and its leaves have been ufed occafionally for culinary purpofes. Its medicinal qualities are owing to its ftypticity or aftringency, which property renders it ufeful in dyeing, and alfo in tanning of leather, to which purpofe it was applied in the time of Diofcorides. The leaves and berries have been ufed in medicine; but the leaves are more aftringent and tonic, and have been commonly employed in complaints which indicate remedies of this clafs. The berries, which are of a red and compreffed figure, contain a pulpy matter, in which is lodged a brown, hard, oval feed, manifefting a confiderable degree of aftringency. The pulp, even when dry, is gratefully acid, and has been found to contain an effential falt fimilar to that of wood-forrel, or perhaps more nearly allied to cryftals of tartar. An infufion of the dry fruit is not blackened by a folution of iron, ſo that it appears to be deſtitute of aſtringency; but its acidity is very grateful, and hence the French have called it "le vinaigrier." Like many other acid fruits, theſe berries, which in eaſtern countries are uſed as a pickle, may be advantageouſly taken to allay febrile heat, and to correct bilious putreſcency. The *rhus toxicodendron* and *radicans* have of late been recommended in paralytic affections; the latter by M. Freſnoi, and the former by Dr. Alderſon of Hull: but the caſes in which theſe virulent plants were employed are but few and indeciſive. They excite, however, a ſenſe of heat and pricking, and irregular twitches in the affected limbs. It is ſuggeſted that ſome advantage has been derived from their uſe in herpetic eruptions. The doſe of the powdered leaves may be gr. ſs, given twice or thrice a day, and gradually increaſed to grs. iv, in the form of a bolus. The ſtems of the toxicodendron, when cut or broken, exude a milky juice, which inflames the ſkin whereever it touches, and becomes black when it is expoſed for a ſhort time to the action of atmoſpheric air. This juice forms an indelible black ſtain on linen cloth, and is uſed in Japan, where it is a native, as a varniſh. (Phil. Tranſ. vol. xlix. p. 158. See Varnish.) The leaves are inodorous, and their taſte is mawkiſh and ſubacrid. Their virtues are completely extracted by water, and partially by alcohol. The aqueous infuſion reddens litmus paper; precipitates the ſolution of iron black, that of nitrate of ſilver brown, and throws down a precipitate with gelatine. Hence it contains gallic acid and tannin; but its effects chiefly depend on a narcotic principle. Woodv. Med. Bot. Thomſon's Lond. Diſp. See Sumach and Toxicodendron.

RHUSELNIUM, in *Botany*, a name given by ſome authors to the ranunculus.

RHUSTICANA, or Rusticana, in *Ancient Geography*, a town of Hiſpania, in the interior of Luſitania, between Talebriga and Mendeculia. Ptolemy.

RHUSUNCORÆ, or Rusucurrum, a town of Africa, in Mauritania Cæſarienſis. Ptolemy. It had the title of a Roman colony.

RHUTHYN, or Ruthin, in *Geography*, a borough and market-town in the cwmwd of Llannerch, cantref of Dyffryn-Clwyd, (now called the hundred of Rhuthyn,) county of Denbigh, North Wales, is ſituated on the ſlope of a conſiderable hill, which riſes near the centre of the delightful vale of the Clwyd, at the diſtance of 205 miles N.W. from London. This town, from the etymology of its name, appears to have derived its origin from a caſtle, called Rhyddin, or the red fortreſs, in alluſion to the colour of the ſtone of which it is conſtructed. Although there was probably a walled fortreſs here anterior to the reign of king Edward I., yet the laſt caſtle erected here was moſt probably by this monarch. Camden, however, aſſigns its origin, as well as the town, to a baron named Roger Gray. Its hiſtory affords only a few events worthy of notice. In the year 1400 Owen Glyndwr attempted to take it by aſſault, but was unſucceſsful; ſo that after pillaging the inhabitants, and ſetting fire to the town, he retreated precipitately to the mountains. In the reign of king Charles I. it was garriſoned in the royal cauſe, till about the middle of April, A.D. 1646, when it was compelled to ſurrender, after having ſuſtained a ſiege of two months. Not long ſubſequent to that period, it was diſmantled by order of parliament, and has ſince gradually fallen into its preſent ruinous ſtate; only a few fragments of walls remaining to mark its ſcite and character.

Rhuthyn is deſcribed as having been formerly a populous town, and as poſſeſſing the beſt market of any in the vale. This pre-eminence, however, is now loſt; though it is yet a reſpectable and flouriſhing place, containing, according to the parliamentary reports of 1811, 271 houſes, and a population of 1292 perſons. The government is veſted in two aldermen and ſixteen common council-men, choſen annually in the lord's court. The number of burgeſſes is unlimited. Rhuthyn is a borough both by preſcription and by charter, and joins with Denbigh in returning a repreſentative to the national ſenate. It has two markets, weekly; one on Saturday for proviſions, and another on Monday for corn, &c.; beſides which, there are ſix annual fairs. The lordſhip of Rhuthyn, a manorial right belonging to the Middleton family of Chirk-Caſtle, compriſes three comots, *viz.* Coleigon, Dogfeilyn, and Llannerch; and is diſtinct with reſpect to government from the hundred, the lord appointing a ſteward to it. Here is a free-ſchool of equal, if not greater, celebrity than any other in North Wales. It was founded and endowed by Gabriel Goodman, D.D., who was dean of Weſtminſter in the reign of queen Elizabeth. His deſcendant, Godfrey Goodman, was likewiſe a benefactor to the town. From this ſchool young men are ſometimes admitted into orders, without having graduated at any univerſity. It has two maſterſhips, the head one of which is in the gift of Jeſus college, Oxford. The town-hall is ſituated near the market-place, and is fitted up with apartments for holding the hundred courts, the county aſſizes, and the quarter ſeſſions; which laſt are held alternately here and at Denbigh. The new gaol is a handſome and commodious building, erected according to deſigns furniſhed by Mr. Joſeph Turner. The debtors' apartments and thoſe of the felons are divided by a lofty wall; and both have ſpacious yards, with baths, attached to them. The church is a large ſtructure of conſiderable antiquity. It was originally conventual, having been attached to a religious houſe of the order of monks denominated Bonhommes. In the year 1310, however, it was made collegiate by John de Gray, who placed in it a chapter of ſeven regular canons, and conferred upon them conſiderable landed poſſeſſions, and numerous privileges. The apartments for the canons were connected with the church by a cloiſter, of which a portion is ſtill remaining, converted into a reſidence for the warden of an hoſpital, which was founded and endowed by Gabriel Goodman, the founder of the free-ſchool, as an aſylum for twelve decayed houſekeepers, *viz.* ten men and two women. The warden is *ex officio* rector of the pariſh of Rhuthyn, and has, beſides, the government of the free-ſchool. The interior of the church is much admired, and particularly its roof, which is a very curious piece of workmanſhip, conſiſting of ſmall ſquares, adorned with various ſculptures, and bearing the names of the different workmen employed in their formation. The collegiate eſtabliſhment here was diſſolved at the period of the general ſuppreſſion, when its lands were granted to William Winlove and Richard Fyld. There are no remarkable monuments in this church, excepting that of Dr. Gabriel Goodman, which diſplays a buſt of the deceaſed, in marble. The doctor was a native of Rhuthyn, where he was born in 1583. He was ſucceſſively advanced to be canon of Windſor, dean of Rocheſter, and biſhop of Glouceſter. See Fuller's Church Hiſtory, book xi. Worthies, and Chalmer's General Biographical Dictionary.

The vicinity of Rhuthyn preſents ſome objects worthy of notice. At a ſhort diſtance from the town is the neat village of Llanrhydd, which is noted for the fine ſculptural monuments and decorations in its church. Near this village is the Bathafarn, anciently a ſeat belonging to the lord Gray; and more to the ſouth-weſt lie Pool-Park and Bachymbyd, both ſeats of the lord Bagot. Stretching towards

wards the north is the vale of Clwyd, which is deſervedly celebrated by all travellers. Commencing at Rhuthyn, it extends not leſs than twenty-four miles in length, and from ſix to eight in breadth, exhibiting a rich ſcene of cultivation, happily blended with many of thoſe objects which conſtitute the picture ſque. On a ſmall eminence in this vale ſtands the village of Llan-Rhaiadar; and near it is a well, called Ffynnon Ddyfnog, which is much eſteemed by the inhabitants for its medicinal quality in the cure of rheumatiſm. The church here is an elegant ſtructure in the pointed ſtyle, and has a beautiful eaſt window, ornamented with ſtained glaſs. The ſubject is the root of Jeſſe, who is repreſented as extended upon his back, with the genealogical tree iſſuing from his loins, compriſing all the kings of Iſrael and Judah, down to the birth of Chriſt. Above is an outline roſe, including an eye ſurrounded with a radiance, and another roſe of Lancaſter to correſpond; which laſt emblem indicates that the work was executed after the acceſſion of Henry VII. to the throne. Here is a ſplendid but taſteleſs monument to the memory of Maurice Jones, eſq., who founded an alms-houſe in this pariſh, A.D. 1720; and in the church-yard is a ſtriking inſtance of genealogical vanity, in an inſcription to the memory of John ap Robert, whoſe pedigree is traced up to Cadel, king of Powis. Carliſle's Topographical Dictionary of Wales, 4to. 1813. A Tour in South Wales, by the Rev. W. Bingley, 8vo. 1801. Pennant's Tour through Wales, 1770, 2 vols. 4to.

RHYAS, from ῥεῖν, *to flow*, in *Surgery*. See RHŒAS.

RHYDDA, in *Ancient Geography*, a town of Paleſtine, belonging to the Arabs, according to Joſephus.

RHYME, RHIME, *Ryme*, or *Rime*, in *Poetry*, the ſimilar ſound or cadence and termination of two words which end two verſes, &c.

Or, rhyme is a ſimilitude of ſound between the laſt ſyllable or ſyllables of one verſe, and the laſt ſyllable or ſyllables of a verſe ſucceeding either immediately, or at a diſtance of two or three lines.

Rhyme is a modern invention, and the product of a Gothic age: Milton calls it the *modern bondage*. Yet ſome authors will have it, that the Engliſh, French, &c. borrow their rhyme from the Greeks and Latins. The Greek orators, they ſay, who endeavoured to tickle the ears of the people, affected a certain cadence of periods, which ended alike, and called them ὁμοιοτέλευτα. The Latins, who imitated them, called theſe chiming terminations, *ſimiliter deſinentia*.

This affectation increaſed as the Latin tongue declined; ſo that, in the later Latin writers, ſcarcely any thing is more common than rhyming periods.

The French, and from them the Engliſh, &c. adopted this cadence of rhyme, which ſeemed to them more pretty and agreeable than the metrical verſes of the Greek and Roman poets.

This kind of Latin poetry in rhyme was much in vogue in the twelfth century; and the verſes thus running were called Leonine verſes, for what reaſon Camden owns he does not know (for a lion's tail, ſays he, does not anſwer to the middle parts, as theſe verſes do); but, doubtleſs, they had their name from a French monk of St. Victor at Marſeilles, about the year 1135, called Leoninus, who firſt compoſed them with ſucceſs, and of whom we have ſeveral pieces in them remaining, addreſſed to pope Adrian IV. and Alexander III. It is certain, however, (ſays Dr. T. Warton, Hiſt. of Engliſh Poetry, vol. i.) that rhymed Latin verſes were in uſe at a much earlier period. Pelloutier (Mem. ſur la Lang. Celt. part i. vol. i. ch. 12.) has given a very early ſpecimen of Latin rhymes, occurring in the beginning of the ſeventh century. Latin rhymes ſeem to have been firſt uſed in the church hymns, but Leonine verſes are properly the Roman hexameters or pentameters rhymed, and it is not improbable, that they had their name from the above-mentioned monk, who was the moſt popular, and almoſt only Latin poet of his time in France. He wrote many Latin pieces not in rhyme, and in a good ſtyle of Latin verſification. The early French troubadours mention a ſort of rhyme in their vernacular poetry partly diſtinguiſhed from the common ſpecies, which they call Leonine or Leonime.

Camden has given us a collection of Latin rhymes of our ancient Engliſh writers; among whom, Walter de Mapes, archdeacon of Oxford, in the time of king Henry II. makes a principal figure, eſpecially for two pieces, the one in praiſe of wine beginning,

> "Mihi eſt propoſitum in taberna mori,
> Vinum ſit appoſitum morientis ori;
> Ut dicant, cum venerint, angelorum chori,
> Deus ſit propitius huic potatori."

The other againſt the pope, for forbidding the clergy to have wives, beginning,

> "Priſciani regula penitus caſſatur,
> Sacerdos per *hic* et *hæc* olim declinatur;
> Sed per *hic* ſolummodo nunc articulatur,
> Cum per noſtrum præſulum *hæc* amoveatur."

Since the reſtoration of learning in the ſixteenth century, attempts have been made to baniſh rhyme out of the modern poetry, and to ſettle the Engliſh and French verſes on the footing of the ancient Greek and Latin ones, by fixing the quantities of the ſyllables, and truſting wholly to thoſe, and to the numbers or meaſure.

This Milton has done, with great ſucceſs, in his Paradiſe Loſt, and other pieces; and after him Philips, Addiſon, and ſome others. Verſes of this kind we call *blank verſes*. See VERSE.

The French have attempted the ſame, but not with the ſame ſucceſs. Jodelet made the firſt eſſay, and after him Paſquier; but they both failed. Paſſerat and Rapin followed them, and failed, like them. Their hexameter and Sapphic verſes were neither imitated nor approved; and the cadence of rhyme was generally preferred to quantity, or the uſe of long and ſhort ſyllables. Des Portes, likewiſe, made ſome eſſays of verſes, conſtructed of long and ſhort lines, without rhyme, but the attempt only ſerved to convince the world, that this kind of meaſure is inconſiſtent with the genius of the French tongue.

To ſucceed in ſuch kind of verſes, there muſt be a liberty of varying the order of the words, or of changing their ſituation, as may beſt ſuit the occaſions of the poet; of making the ſubſtantive either go before or follow after the verb, as the verſe requires, &c. Now none of the modern tongues will admit of ſuch an arbitrary ſituation of the words, equally with the ancients; yet none will allow this more than the Engliſh, nor any leſs than the French.

The principal defect in rhyme is the full cloſe which it forces upon the ear at the end of every couplet; and in this reſpect it is far inferior to *blank verſe*; (which ſee.) Beſides, the conſtraint and ſtrict regularity of rhyme are unfavourable to the ſublime, or to the highly pathetic ſtrain.

An epic poem, or a tragedy, would be fettered and degraded by it. It is beſt adapted to compoſitions of a temperate ſtrain, where no particular vehemence is required in the

the ſentiments, nor great ſublimity in the ſtyle; ſuch as paſtorals, elegies, epiſtles, ſatires, &c. To theſe it communicates that degree of elevation, which is proper for them, and, without any other aſſiſtance, ſufficiently diſtinguiſhes the ſtyle from proſe. He who ſhould write ſuch poems in blank verſe, would render his work harſh and unpleaſing. In order to ſupport a poetical ſtyle, he would be obliged to affect a pomp of language unſuitable to the ſubject. Dr. Blair farther obſerves, that though he coincides in opinion with thoſe, who think that rhyme finds its proper place in the middle, but not in the higher regions, of poetry, can by no means join in the invectives which ſome have poured out againſt it, as if it were a mere jingling of ſounds, fit only for children, and owing to nothing but the corruption of taſte in the monkiſh ages. Rhyme might indeed be barbarous in Latin or Greek verſe, becauſe theſe languages, by the ſonorouſneſs of their words, by their liberty of tranſpoſition and inverſion, by their fixed quantities and muſical pronunciation, could carry on the melody of verſe without its aid. But it does not follow, that it muſt, therefore, be barbarous in the Engliſh language, which is deſtitute of theſe advantages. Rhyme was barbarous in Latin; and an attempt to conſtruct Engliſh verſes, after the form of hexameters and pentameters, and Sapphics, is as barbarous among us. It is not true, that rhyme is merely a monkiſh invention. On the contrary, it has obtained under different forms in the verſification of moſt known nations. It is found in the ancient poetry of the northern nations of Europe; and it is ſaid to be found among the Arabs, the Perſians, the Indians, and the Americans. This ſhews, that there is ſomething in the return of ſimilar ſounds, which is grateful to the ears of the greateſt part of mankind. And if any one, after reading Mr. Pope's Rape of the Lock, or Eloiſa to Abelard, ſhall not admit our rhyme, with all its varieties of pauſes, to carry both elegance and ſweetneſs of ſound, his ear muſt be pronounced to be of a very peculiar kind.

The preſent form of our Engliſh heroic rhyme in couplets is a modern ſpecies of verſification. The meaſure generally uſed in the days of queen Elizabeth, king James, and king Charles I., was the ſtanza of eight lines, ſuch as Spencer employs, borrowed from the Italian; a meaſure very conſtrained and artificial. Waller was the firſt who brought couplets into vogue; and Dryden afterwards eſtabliſhed the uſage. Waller firſt ſmoothed our verſe; Dryden perfected it. Mr. Pope's verſification has a peculiar character. It is flowing and ſmooth in the higheſt degree; far more laboured and correct than that of any who went before him. He introduced one conſiderable change into heroic verſe, by totally throwing aſide the triplets, or three lines rhyming together, in which Mr. Dryden abounded. Dryden's verſification, however, has great merit; and, like all his productions, has much ſpirit mixed with careleſſneſs. If not ſo ſmooth and correct as Pope's, it is however more varied and eaſy. He ſubjects himſelf leſs to the rule of cloſing the ſenſe with the couplet, and frequently takes the liberty of making his couplets run into one another, with ſomewhat of the freedom of blank verſe. Blair's Lect. vol. iii. See Verse.

Rhymes are either *ſingle*, or *double*, or *triple*, though the two laſt are now much diſuſed.

Rhymes, *Single*, are divided into perfect or whole rhymes, and imperfect or half rhymes. *A whole* or *perfect* rhyme is where there is a ſimilitude of ſound without any difference; or where a thorough identity of ſound appears in the pronunciation of the two ſyllables, notwithſtanding that there may be ſome difference in the orthography. *A half* or *imperfect* rhyme is where there is a ſimilitude, with a difference either in reſpect of the pronunciation, or the orthography, but chiefly the former.

Rhyme, *the feminine*, is that where the laſt ſyllable of the rhyme ends with an *e* mute, or quieſcent, as in *dove*, *belle*, &c.

Rhymes, *Maſculine*, are thoſe of all other words.

Menage obſerves, that the maſculine rhymes cloſe the periods better; but the feminines, being the ſofter and more languiſhing, end more agreeably, eſpecially in mournful ſubjects.

Rhymes, *Double*, by the French called *rich* rhymes, are thoſe where the two words terminate alike through the whole two laſt ſyllables, as *ſquabble* and *rabble*, &c.

Rhymes, *Plain*, are thoſe where the two rhyming verſes ſucceed immediately to each other.

Rhymes, *Croſs*, are thoſe where the verſes are ſo diſpoſed, as that the firſt rhymes with the third, and the ſecond with the fourth, &c.

Rhymes, *Aſſonant*. See Assonant.

RHYMNICI Montes, in *Ancient Geography*, mountains of Scythia, on this ſide of Imaus, in which the river Rhymnus had its ſource. The mouth of this river was in the Caſpian ſea, between that of the river Rha and that of the river Daïs.

RHYNBECK, or Rhinbeck, in *Geography*, a poſt-town of America, in Dutcheſs county, New York, on the E. ſide of Hudſon's river, oppoſite to Kingſton; 103 miles N. of New York. The townſhip is bounded S. by Clinton, and N. by Beckman. A curious cavern has been diſcovered, in 1792, at a place in this town, called by the Indians Sepaſcot.

RHYNCHÆ, in *Ancient Geography*, a country of Greece, in the iſle of Eubœa. Steph. Byz.

RHYNCHOSPORA, in *Botany*, ſo called from ῥύγχος, *a beak*, and σπορὰ, *ſeed;* becauſe the permanent baſe of the ſtyle forms a beak to the ſeed.—Vahl. Enum. v. 2. 229. Brown Prodr. Nov. Holl. v. 1. 229. Ait. Hort. Kew. v. 1. 127.—Claſs and order, *Triandria Monogynia*. Nat. Ord. *Calamariæ*, Linn. *Cyperaceæ*, Brown.

Eſſ. Ch. Glumes chaffy; the lower ones empty. Corolla none. Seed one, crowned with the hardened permanent ſtyle, whoſe baſe is as broad as the ſeed.

Vahl, the founder of this genus, deſcribes nineteen ſpecies, among which are *Schoenus albus* and *fuſcus* of Linnæus, and Sm. Fl. Brit. Mr. Brown adopts it, adding to the character, that "the ſeed is accompanied at its baſe by toothed briſtles, ſhorter than the glumes." He remarks, that it differs from Dichromena, (ſee that article,) in having theſe briſtles. This writer defines three New Holland ſpecies, one the *R. aurea* of Vahl, and other two nondeſcripts. The infloreſcence is ſaid to be very various, ſome ſpecies having the flowers panicled, whilſt in others they are either corymboſe, or capitate. We do not ſee the neceſſity of eſtabliſhing this genus; at leaſt, as it concerns the Britiſh Flora, we beg leave to ſuſpend our opinion. See Schoenus.

RHYNCOSIA, from ῥύγχος, *a beak*, becauſe the keel terminates in a long ſharp point.—Loureir. Cochin. 460. Claſs and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminoſæ*, Juſſ.

Eſſ. Ch. Corolla papilionaceous. Keel rhomboid, beaked. Legume membranous, with two ſeeds.

1. R. *volubilis*.—Found wild near Canton in China. *Stem* herbaceous, round, twining. *Leaves* ternate, roundiſh, downy. *Flower-ſtalks* axillary, in pairs, many-flowered. *Calyx* two-lipped. *Corolla* yellow. *Seeds* black and ſhining.

In

In ſo difficult a tribe, we dare not anſwer for the permanency of this genus, not having ſeen a ſpecimen. The plant may poſſibly be known to botaniſts, under ſome other name and genus.

RHYNCOTHECA, from ῥυγχος, *a beak*, and θηκη, *a capſule*, on account of its beaked or pointed ſeed-veſſel. De Théis Gloſſaire de Botanique, 402. Fl. Peruv. 71.

RHYNDACUS, in *Ancient Geography*, a river of Aſiatic Myſia, according to Pomponius Mela, who places its ſource in mount Olympus. According to Pliny it had been denominated Lycus.—Alſo, a town of Aſia, between Phrygia and the Helleſpont. Steph. Byz.

RHYNE, in *Botany*, a name uſed by ſome authors for the camphor tree.

RHYPÆ, RIPE, or *Rhypes*, in *Ancient Geography*, a town of the Peloponneſus, in Achaia, the territory of which was denominated Rhypidis. According to Strabo it was N. of Helice, and at ſome diſtance from the coaſts of the gulf of Corinth. Pauſanias ſays that in his time they could only perceive the ruins of Rhypæ, 30 miles from Ægium. Homer calls this town Répe.

RHYPARA, an iſland ſituated near that of Samos. Pliny.

RHYPTICS, RHIPTICS, Ῥυπτικα, in *Medicine*, detergent remedies, or cleanſers. See DETERGENT.

RHYSSADIUS, in *Ancient Geography*, a mountain of Africa, in Lybia interior, in which Ptolemy places the ſource of the river Stachir.

RHYSTROM, in *Geography*, a river of Holſtein, which runs into the Elbe at Gluckſtadt.

RHYTHM, RHYTHMUS, Ῥυθμος, in *Muſic*, the variety in the movement, as to the quickneſs or ſlowneſs, and length and ſhortneſs, of the notes.

Or the rhythmus may be defined, more generally, the proportion which the parts of a motion bear to each other.

In *ancient poetry* rhyth or rhythm denotes the meaſure of the feet, or the number and combination of long and ſhort ſyllables, called alſo *metre* and *quantity*.

A continued motion in every organized body that is capable of rhythm, is ſuſceptible of ſome kind of meaſure. This meaſure marks the ſeveral parts of motion, and enables us to judge of their proportions. It is to point out theſe proportions that the Greeks, among many other terms, have made uſe of ῥυθμος, *rhythm*, which they have applied to different purpoſes. They have not only expreſſed by it the kind of cadence, or vibration of the wings, in the flight of birds; the movement of the feet in the progreſſive motion of animals; and the geſtures, figures, and ſteps of dancers; but every ſpecies of regular motion, ſuch as is obſervable in the beating of the pulſe, and in reſpiration. They have even abuſed the original import of the word ſo far as to apply it to things abſolutely motionleſs and inanimate; ſuch as works in painting and ſculpture, in which they have called that ſymmetry and juſt proportion which reigns in all the parts by the name of rhythm.

But the moſt common application of this term has been to expreſs the *time* or duration of many ſounds heard in ſucceſſion; whether theſe ſounds are muſical, and ſuch as are produced by voices and inſtruments, or without any determinate tone, as in the ſtrokes of a hammer upon an anvil; in the beating of a drum; and in the articulations of the voice in common ſpeech, in repeating poetry, or pronouncing an oration.

But our enquiries here ſhall be confined to that ſpecies of rhythm, which more particularly concerns melody, and which merits diſcuſſion the more, on account of its great importance in muſic, and of the darkneſs in which it is uſually involved by writers on the ſubject.

From the ſtrict union of poetry and muſic among the ancients, which ſeem to have been almoſt inſeparable, an offence againſt time or rhythm was unpardonable, as it not only deſtroyed the beauty of the poetry, but ſometimes even the meaning of the words of which it was compoſed. Το παν παρα μουσικοις ὁ ῥυθμος, ſay the Greeks; it was the principal point in their muſic, without which they regarded melody as wholly unmeaning and lifeleſs. Hence Plato refuſed the title of muſician to every one who was not perfectly verſed in rhythm, as we ſhould now to a bad *timeiſt*. It is of ſuch importance, that, without it, muſic can have no power over the human paſſions. Pythagoras, according to Martianus Capella, uſed to call rhythm, in muſic, the *male*, and Melos the *female*; and Doni has compared rhythm with *deſign*, in painting, and Melos to *colouring*. It is certain that an ordinary melody, in which the time is ſtrongly marked, and the accents are well placed, has more effect than one that is deficient in thoſe particulars, though more refined and uncommon, and ſet off with all the richneſs of harmony, and learning of modulation.

Iſaac Voſſius, in his Diſſertation "De Poematum Cantu, et viribus Rhythmi," has attributed to rhythm all the miraculous powers of ancient muſic.

As vocal muſic was chiefly cultivated among the ancient Greeks, the firſt part of theſe rhythmical obſervations ſhall be confined to lyric poetry.

Ariſtides Quintilianus defines muſical rhythm συστημα εκ χρονων κατα τινα ταξιν συγκειμενων; "the aſſemblage of many parts of time, which preſerve a certain proportion with each other;" which, ſince the uſe of bars in muſic, may be called aliquot parts of a meaſure, or a given portion of time. For the better underſtanding of this definition, it is neceſſary to remember that the muſic in queſtion was conſtantly ſung to verſes, the words of which were all compoſed of *long* and *ſhort* ſyllables; that the ſhort ſyllable was pronounced as quick again as the long, and the ſhort ſyllable being regarded as one part or portion of this meaſure, the long was equal to two; ſo that, conſequently, the ſound which was applied to the long ſyllable, was equal in duration to two ſuch ſounds as were ſung to ſhort ſyllables, or, in other words, that one note was equal to two portions of time, and the other to one. It muſt likewiſe be remembered that the verſes thus ſung, were compoſed of a certain number of feet, formed by theſe long and ſhort ſyllables differently combined, and that the rhythm of the melody was regulated by theſe feet; as, whatever was their length, they were always divided into two parts, equal or unequal, the firſt of which was called αρσις, *elevation*, and the ſecond θεσις, *depreſſion*. A *foot* in poetry ſeems to anſwer to a *bar* in muſic. A *time*, among the ancients, was a proportion of that foot or bar; as, with us, a bar is divided into accented and unaccented parts. In like manner the rhythm of the melody, correſponding with theſe feet, was divided into two parts, equal or unequal, which we now call the *down* and *up* parts of a bar, expreſſed by *beating down* the hand or foot, and *lifting it up*. Thus far concerns *vocal* rhythm; what follows belongs to *inſtrumental*.

As the notes of the ancient muſic were conſtantly written over each ſyllable of the verſes which were to be ſung; as the quantity of each of theſe ſyllables was perfectly known to muſicians; and as the duration of each ſound was regulated by the ſyllables; it did not ſeem neceſſary that the time ſhould be marked by any particular ſign or character. However, for the eaſe and convenience of the muſician, a canon,

canon, or rule, was given of the rhythm at the beginning of a lyric poem. This canon consisted of nothing but the numbers 1 and 2, that is, the alpha and beta of the Greek alphabet, disposed according to the order of the breves and longs which composed each verse, and divided according to the number of its feet. The alpha, or unit, marked a breve, because it contained only one portion of time; and the beta, or binary, marked a long, being equal to two portions. Some of these poetical, or rhythmical canons, are still to be found in the Manual of Hephæstion.

Rhythm in Latin was called *numerus;* and this term, in process of time, was extended to the melody itself, subjected to certain numbers or rhythms, as appears from this line of Virgil:

"Numeros memini, si verba tenerem:"

"If I knew the words, I could remember the tune well enough."

The Romans had signs for rhythm, as well as the Greeks; and these signs were not only called *numerus*, but *æra*, that is, *number*, or the mark for time. *Numera nota*, says Nonius Marcellus. In this sense we find the word used in a verse of Lucilius:

"Hæc est ratio? perversa æra? summa subducta improbè?"

"Do you call that settling accounts? such a confusion of figures? and the sum falsely cast up?"

Though the word *æra* was at first only applied by musicians to the time, or measure of the melody, they afterwards made the same use of it as of *numerus*, to express the tune or melody itself; and it has been thought that the word *air*, or, as the Italians call it, *aria*, which includes a certain piece of music of a peculiar rhythm, or cadence, is derived from *æra*.

Such was the manner in which the ancients marked the measure in their written music; but to make it still more sensible in the execution, they beat time in several different ways. The most common was by the motion of the foot, which was lifted up and beat down alternately, according to what we call common, or triple time. To regulate the time was generally the office of the music master or director, called μεσοχορος and κορυφαιος, *coryphæus*, because he was placed in the middle of the orchestra, among the musicians, and in an exalted and conspicuous situation, in order to be seen and heard the more easily by the whole band.

The directors of the time were likewise called in Greek ποδοκτυποι and ποδοψοφοι, from the noise of their feet. In Latin they were called *pedarii*, *podarii*, and *pedicularii*, for the same reason. Their feet were generally furnished with wooden or iron sandals, in order to mark the time in a more distinct manner; these implements the Greeks called κρουπεζια, κρουπαλα, κρουπετα; and the Latins *pedicula*, *scabella*, or *scabilla*, because they resembled little pattens, or clogs.

But it was not only with the feet that the ancients beat the time, but with all the fingers of the right hand upon the hollow part of the left; and he who marked the time or rhythm in this manner, was called *manu-ductor*. For this purpose they sometimes used oyster-shells, and the shells of other fish, as well as the bones of animals, in beating time, as we do of castanets, tabors, &c. Both Hesychius, and the scholiast of Aristophanes, furnish passages to confirm this assertion. What a noisy and barbarous music! All rhythm, and no sound. The drums and systrums of the Idæi Dactyli could not have been more savage.

Many ancient instruments were monotonous, and of little use, but to mark the measure; such were the cymbalum and systrum; and it was for this reason, perhaps, that the cymbal was called *æra*, by Petronius. But it would afford us no very favourable idea of the abilities of modern musicians, who should require so much parade and noise in keeping together. The more time is beat, says M. Rousseau, the less it is kept; and, in general, bad music, and bad musicians, stand most in need of such noisy assistance.

However, if any thing like the power which ancient music is said to have had over the passions can be credited, it must have derived this power chiefly from the energy and accentuation of the rhythm. Aristides Quintilianus gives a long list of different metres, with their several properties of calming or agitating the mind, according to the nature of the syllables, or feet of the verses, as well as the sentiments which they were intended to express; and as it will afford the reader an opportunity of seeing how much stress was laid on this part of music, and how fanciful and ideal many of the distinctions seem to have been, we shall give the whole passage in English.

"Measure, which begins by a *down part* of the metrical division, is calm and gentle; whereas that which begins by an *up part*, expresses trouble and agitation. Full time, that is, always accompanied with melody, is noble in its effect; and that arising from catalectic verses, deficient in a syllable or note, if it be supplied by a rest or pause, has more simplicity. Time of equal proportions, is graceful; and that of odd numbers, or sesquialterate proportion, is more proper to excite commotion. Double time is a kind of mean betwixt the graceful and the turbulent. Among the movements of two even notes, if they are short, their effect is lively, impetuous, and proper for military dances, called *Pyrrhics*, in which the dancers are armed; and time, of which the movement is regulated by poetic feet composed of long syllables, is more grave, serious, and fit for hymns which are sung in honour of the gods, at festivals, and in sacrifices; the measure composed of a mixture of long and short notes, participates of the qualities of both these last mentioned.

"Among the duplicate proportions, the Iambic and Trochaic have the most vivacity and fire, and are peculiarly proper for dancing. Those called ορθιοι and σημαντοι, of which the arsis answers to two long syllables, are full of dignity. Compound measures are more pathetic than simple; and such as are confined to one genus, move the passions much less than those which pass from one genus to another."

After giving these characteristics of time, Aristides proceeds to prove their reality and foundation in nature, by drawing a parallel between some particular species of rhythm, and the gait and actions of man. He pretends, for instance, "that the motion which answers to the Spondaic measure, is a sign of moderation and fortitude; that Trochaics, or Pæans, indicate a greater degree of fire and vivacity; that the Pyrrhic has something low and ignoble in it; that an irregular velocity implies dissoluteness and disorder; and finally, that a movement resulting from all these, is wild and extravagant."

With respect to the excellence and effects of ancient music, it is very difficult to steer between the extremes of credulity and scepticism. Such enthusiasts as Aristides Quintilianus, by asserting too much, have thrown a ridicule upon the subject, and inclined us, perhaps, to believe too little. The simplicity of ancient melody, and its slavish dependence upon poetry, may probably have given birth to some of these fancies.

In addition to the account already given of the poetic feet under their respective articles, we shall here introduce a short

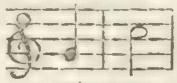
short description of each as they more immediately relate to music, at the same time rendering our dissertation on rhythm more complete.

A poetical foot consists of a certain number of syllables, which constitutes a distinct part of a verse, as a bar does of an air in music. An hexameter verse consists of six of these feet, a pentameter of five.

The Spondee, Iambus, Trochee, and Pyrrhic or Periambus, are dissyllabic feet, or of two syllables each.

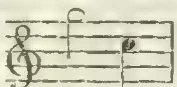
The Spondee consists of two long syllables, as *vertunt*. ¯ ¯

An Iambic foot has one short and one long syllable. Θεὸς, λέγω. *potens*, *amas*. ˘ ¯



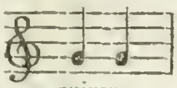
return.

The Trochee has one long and one short syllable, as *gratus*, *musa*. ¯ ˘



silent.

The Pyrrhic, or Periambus, two short syllables, as *mare*, *probus*. ˘ ˘



quiver.

The Dactyl, Anapæst, Molossus, Tribrach, Bacchius, Antibacchius, Amphibrachys, and Creticus, are trisyllabics, or of three syllables. To some of these we have no equivalents; however, the Dactyl, consisting of one long and two short syllables ¯ ˘ ˘  is very common in our language, as *tenderly*, *hastily*; and we have verses composed of dactyls as well as the Greeks and Romans:

> Mȳ | bānks thĕy wĕre | fūrnĭsh'd wĭth | bēes,
> Whōse | mūrmŭrs ĭn- | vīte ōne tŏ | slēep.

These may be compared with the following celebrated passages in Homer and Virgil, where the sound is manifestly, and intentionally, an *echo to the sense*. Homer (Odyssey, book xi.) after he has described in labouring Spondees the slow and painful manner in which Sysiphus rolled the stone up hill, makes use of nimble Dactyls in describing its swift descent:

> Αὖτις ἔπειτα πέδονδε κυλίνδετο λᾶας ἀναιδής.

And Virgil, lib. viii. v. 596, describes, in pure Dactyls, the galloping of the horse:

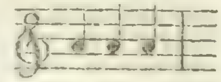
> " ———— It clāmŏr, ĕt āgmĭnĕ fāctō
> Quādrŭpĕdāntĕ pŭtrēm sŏnĭtū quătĭt ūngŭlă cāmpūm."

The Anapæst has two short and one long syllable; as *sapiens*, *recubans*, ˘ ˘ ¯ . Isaac Vossius, "De Viribus Rhythmi," p. 56, has said, that the French have no Dactyls, nor the English a perfect Anapæst in their language. Let the French speak for themselves; but as to our own part of the charge, it is easily confuted by the mere mention of the words *recommend* and *disappoint*.

We shall enumerate the rest of the poetic feet of the ancients, merely to shew what resources they had in varying their melody by different combinations of two kinds of notes.

The Molossus has three long syllables, ¯ ¯ ¯

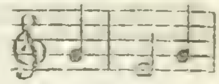
The Tribrach, three short, ˘ ˘ ˘



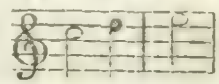
The Bacchius, which is the reverse of the Dactyl, has one short, and two long syllables, ˘ ¯ ¯

The Antibacchius, two long and one short, ¯ ¯ ˘

Amphibrachys, one short, one long, and one short, or one long between two short, ˘ ¯ ˘



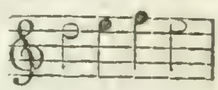
Creticus, one short between two long, ¯ ˘ ¯



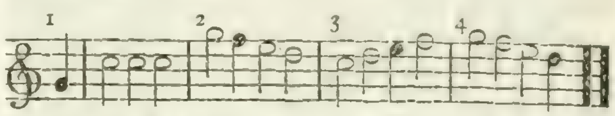
The quadrisyllabics are compounded of feet already mentioned.

The Proceleusmaticus is composed of four short syllables, or of two Pyrrhics, ˘ ˘ ˘ ˘

The Choriambus, two short between two long, or the junction of the Trochæus and Iambus, ¯ ˘ ˘ ¯



Epitrite; of this foot there are four species: 1. The Iambus and Spondee ˘ ¯ ¯ ¯: 2. The Trochee and Spondee ¯ ˘ ¯ ¯: 3. The Spondee and Iambus ¯ ¯ ˘ ¯: and 4. The Spondee and Trochee ¯ ¯ ¯ ˘.



The Pæan or Pæon, which is the contrary of this last, consists of one long syllable, and three short: ¯ ˘ ˘ ˘, ˘ ¯ ˘ ˘, ˘ ˘ ¯ ˘, ˘ ˘ ˘ ¯.

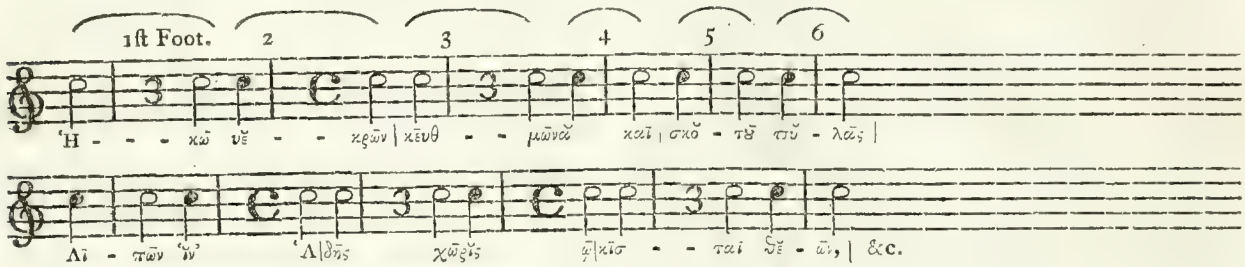
Servius reckons more than a hundred different kinds of verse among the Latins; and, according to Hephæstion, the number was still more considerable among the Greeks; consequently their melody might have been varied in as many different ways. There is not, however, the least appearance of the ancients having had in their vocal music that kind of measure which we call pointed; nor did they admit rests in the middle of a verse, though at the end of catalectic, or broken verses, the singer was allowed to make up the deficiency by a silence, equivalent to a rest in modern music; and though they had so great a variety of feet in their poetry, many of those already instanced are unfit for modern melody.

"After all the researches," says Dr. Burney, "which I have been able to make, it must be acknowledged that the subject of ancient music, in general, still remains, and probably ever will remain involved in much difficulty and uncertainty. It is fortunate, however, for those who wish to view as near as possible this dark angle of antiquity, that the prospect happens to be the clearest just in that part where all its admirers assure us it is best worth examining; for

for however ignorant we may be of the melody of ancient muſic, the rhythm, or time of that melody, being regulated entirely, as has been already obſerved, by the metrical feet, muſt always be as well known to us as the proſody and conſtruction of the verſe; ſo that we have nothing to do but to apply to the long and ſhort ſyllables any two notes, one of which is double the length of the other, in order to know as exactly as if we heard, in what manner any particular kind of metre was ſet by the ancients with reſpect to time and cadence, that boaſted rhythm, which we are ſo often told was *every thing* in their muſic. It may, therefore, afford ſome gratification to the curioſity of thoſe who have never conſidered the poetry of the ancients in this point of view, if I produce a few examples, which will, perhaps, help to throw a little light upon the *dramatic* muſic of the Greeks, and give ſome idea of the rhythmical reſources of the *poet-muſician* in one of the moſt intereſting provinces of his art.

"The firſt example ſhall be of the Iambic verſe, which chiefly prevails in the Greek tragedies, and in which the dialogue and ſoliloquy, indeed all but the chorus and ode, were generally written. I ſhall content myſelf with applying notes of correſpondent lengths to the ſyllables, and marking the time; leaving the melody to the imagination of the reader. Should I preſume to ſupply it, I might expect to be reproached as another Salmoneus for my temerity.

"Demens! qui nimbos et non imitabile fulmen, &c."



This meaſure, when pure and unmixt, conſiſted of ſix Iambic feet, as,

ĕquēs | ſŏnān|tĕ vēr|bĕrā|bĭt ūn|gŭlā.

Such verſes, however, ſeldom occur. The laws of this metre only required that the ſecond, fourth, and laſt feet ſhould be Iambics; in the other places, Spondees, Anapæſts, and Dactyls, were admitted. This metre anſwers to our Alexandrine, or verſe of twelve ſyllables; but more exactly in the *number* and *kind* of feet, than in its cadence, or general effect upon the ear. The pauſe after the third foot, ſo eſſential to a melodious Alexandrine, has no place but by accident, in the Iambic, which runs more ſwiftly, and has a more proſaic effect. This, undoubtedly, led the ancients to meaſure it *per dipodiam*, or by *double* feet (ſee Hor. Art. Poet. v. 252. pes citus: unde, &c.), which anſwer to double bars in modern muſic. Arioſto wrote ſome comedies in this Iambic meaſure. One of his lines will, perhaps, be as exact a repreſentation of the ancient Iambic as can be produced, in point of cadence.

Per dio ſon qua|ſi in penſier di | tornarmene.

The following Alexandrine of Spenſer may alſo ſerve for the ſame purpoſe.

"So in his angry courage fairly pacified."

The above Greek lines are the beginning of the Hecuba of Euripides, and were ſung by the ghoſt of Polydorus. The bars in the verſe are only to ſhew how the ancients divided it into three portions of two feet in each; but the bars of time, the theſis, or beat, muſt always fall in the middle of the foot: ˘ | ¯ | . For the ſake of diſtinguiſhing the feet more clearly, Dr. Burney barred them ſingly; though it would have been more conformable to the ancient manner of ſcanning this kind of verſe, and probably more expreſſive of its cadence and *effect*, to have made but three bars in each line. The Iambics of Greek comedy differ from theſe only in a little more liberty of conſtruction; thoſe of the Roman, in Plautus and Terence, are ſo licentious, as often not to differ perceptibly from proſe, even in the judgment of Cicero himſelf: "propter ſimilitudinem ſermonis, ſic ſæpe ſunt abjecti, ut nonnunquam vix in his numerus et verſus ſentiri poſſit." Orator, cap. 55.

Beſides this metre, the dialogue admitted, occaſionally, Trochaic verſes. They are generally introduced in ſcenes of hurry and diſorder; being, as Ariſtotle has deſcribed them, and as their name implies, a voluble and *dancing* meaſure. A character which the reader will not be inclined to diſpute, when he compares the ancient Trochaic with a meaſure exactly correſponding to it in our own language, but which we have not yet admitted into our tragedy.

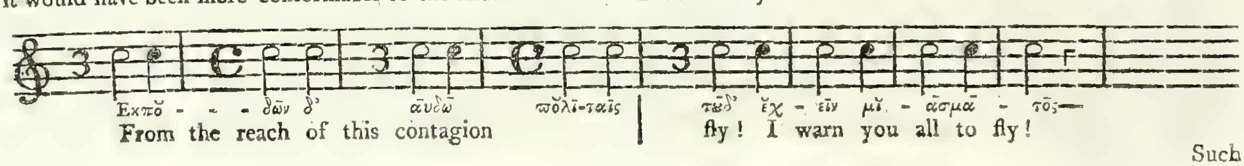
Πᾶ 'στιν οὗτος, ὃς πέφυκε | τοὐμὸν ἐκ δόμων ξίφος;

This is a pure Trochaic, and is preciſely in the meaſure of our

"Jōllў mōrtăls fīll yoūr glăſſĕs,
Nōblĕ deēds ăre dōne by wīne."

The whole difference is, that the ancient Trochaics were written in one line; but this is merely to the eye; for they really conſiſt of two verſes; the laſt ſyllable of the *fourth* foot being, as Dr. Burney believes, conſtantly, the end of a word.

Mr. Weſt, in his tranſlation of the "Iphigenia in Tauris" of Euripides, has given a whole ſcene of Trochaics in the correſpondent Engliſh meaſure. A ſingle line of the original, with his tranſlation, will be a ſufficient example of Trochaic rhythm.



Such

Such were the metres appropriated to the dialogue of the ancient tragedy, and ſuch muſt have been the rhythms or times of the muſic to which they were ſet.

We ſhall cloſe theſe obſervations with one example more, taken from the *choral* part of the drama, that part which was more particularly *muſical*, and the circle marked out for the muſician, where all the magic of his art, with all the wonders of rhythm, were to be diſplayed. Of the metre of this part, we ſhall only obſerve, in general, that it ſeems to have admitted of ſuch an unbounded variety in the mixture and arrangement of feet, and to have been fettered by ſo few reſtraints, that, to a modern ear, it is frequently not to be diſtinguiſhed from a ſmooth and elegant proſe. We can therefore be certain of nothing, concerning the muſic applied to the ancient chorus, except the *relative lengths* of the notes as they are determined by the proſody: in what manner the ancients divided them by beats, we do not even preſume to gueſs; and we believe it may be propoſed to the muſical reader as a problem, worthy, for its difficulty at leaſt, if not for its importance, to exerciſe his ſagacity, how the following ſpecimen ſhould be *barred*, in order to render it as little tormenting to the ear as poſſible.

The moſt ſtriking circumſtance in all theſe examples, is the perpetual change of time, occaſioned by the mixture of unequal feet. To the eye, indeed, the recitative of the old French opera preſents a ſimilar appearance; but where no ſtrict time is obſerved, the changes are leſs perceptible to the ear. No circumſtance relative to ancient muſic has been more frequently and triumphantly oppoſed to the modern, in proof of ſuperiority, than its inviolable adherence to the *fixed quantity* of ſyllables. It is, perhaps, equally difficult to diſprove this, and to conceive how ſuch a muſic could be rigorouſly executed, without throwing both the hearers and performers into convulſions. If, however, this was the caſe, we need no longer wonder at the noiſy expedients, to which the ancients had recourſe in beating time; for we believe the beſt modern band would find it difficult, if not impoſſible, to keep exactly together in the execution of a Greek chorus, though aſſiſted by all the clatter of an ancient coryphæus.

Upon the whole, perhaps, even the imperfect view which we have here attempted to give of the rhythmical reſources of ancient muſic, may be ſufficient to warrant ſomething more than a doubt, whether, after all that Iſaac Voſſius, and many others, have ſaid, a *fixed* proſody, and the rigorous, unaccommodating length of ſyllables, be any recommendation of a language *for muſic;* that is, whether a muſic formed and moulded cloſely upon ſuch a language, muſt not neceſſarily be cramped and poor, in compariſon of that free, unſhackled variety; that independent range of rhythmical phraſe, which conſtitutes ſo conſiderable a part of the riches of *modern* muſic. Let the moſt inventive compoſer try to ſet half a dozen Hexameters, pure Iambics, or any other verſes that will fall into regular common or triple time, and he will ſoon find that no reſources of melody are ſufficient to diſguiſe or palliate the inſipid and tireſome uniformity of the meaſure; and as for any thing like expreſſion, we may as well expect to be affected by the mechanical ſtrut of a ſoldier upon the parade. In other metres, ſuch as thoſe already given in the preceding examples, where feet of different times are intermixed, *ſome* variety is indeed acquired; but it is a miſplaced variety, which, without obviating the tireſome effect of a confinement to no more than *two* lengths of notes, adds to it that of an aukward and uncouth arrangement; the ear is ſtill fatigued with uniformity where it requires change, and diſtracted by change where it requires uniformity.

Modern muſic, on the contrary, by its diviſion into *equal* bars, and its *unequal* ſubdiviſion of theſe bars by notes of various lengths, unites to the pleaſure which the ear is by nature formed to receive from a regular and even meaſure, all the variety and expreſſion which the ancients ſeem to have aimed at by ſudden and convulſive changes of time, and a continual conflict of jarring and irreconcileable rhythms.

Nothing ſeems more eſſential to muſical pleaſure, than the diviſion of melody into equal portions of time, or bars. Quintilian attributed to this natural menſuration of the ear, the firſt production of poetry: "Poema—aurium menſurâ, et ſimiliter decurrentium ſpatiorum obſervatione eſſe generatum."[1] Hexameters and Iambics appear to have been the moſt ancient Greek metres; and the latter, if we may credit Horace, Art. Poet. 253, were at firſt *pure* and uncompounded. The mixture of *unequal* feet, and the Dithyrambic licence of lyric poetry, were later refinements. The progreſs of muſical rhythm was, of courſe, the ſame. Plutarch expreſsly ſays, in the dialogue de Muſicâ, that the compoſitions of Terpander, and other old maſters, were ſet to Hexameters, chiefly of Homer; that is, they were in regular common time. The change and intermixture of rhythms is ſpoken of as the innovation of modern artiſts. Plato rejects theſe complicated meaſures from the muſic of his republic; and even Iſaac Voſſius, the great champion of ancient rhythm, who aſſerts that "no man can be a good muſician, that is not a *good drummer*," owns, p. 11, that "vitioſum et incompoſitum imprimis, fiet carmen, ſi duorum, trium, quatuor, pluriumve temporum pedes, veluti Pyrrichii, Iambi, Dactyli, Pæones, Ionici, ſimul copulentur;" though this is done continually, not only in the lyric part, but even in the dialogue of the ancient drama.

It is evident, from the proofs already given, that the Greeks and Romans had but two different degrees of long and ſhort notes; and even the old lozenge and ſquare cha-

 racters

racters ſtill uſed in the canto fermo of the Romiſh church, under the denomination of Gregorian notes, are but of two kinds; the time of theſe may, indeed, have been accelerated or retarded, but ſtill the ſame proportion muſt have been preſerved between them; and all their variety muſt have ariſen from different combinations of theſe two kinds of notes, ſuch as any two of ours could afford; as ſemibreves and minims, minims and crotchets, or crotchets and quavers.

This accounts for the facility with which even the common people of Greece could diſcover the miſtakes, if any were committed, in the length and ſhortneſs of the ſyllables, both with reſpect to the poetry, and the muſic, a point of hiſtory in which all writers agree; for beſides the intervals peculiar to the melody, rhythm, or time, muſt have contributed to characterize the modes, though it has no kind of connection with our flat and ſharp keys; and this gives an idea quite different from what our modern modes, taken as keys, and our muſic, in general, furniſh. Tartini, upon this ſubject, ſays, that we make the proſody ſubſervient to the muſic, not the muſic to the proſody; and adds, "that as by the laws preſcribed to the ancient muſicians, they were obliged to preſerve rigorouſly in their muſic the quantity of ſyllables, it was impoſſible to protract a vowel, in ſinging, beyond the time which belonged to a ſyllable; we, on the contrary, prolong the vowels through many bars, though in reading they are oftentimes ſhort."

Tartini, however, in pure courteſy, allows to the ancients a diſcretionary power of making ſyllables longer or ſhorter than rigorous time would admit, in order to diverſify expreſſion, and to enforce the paſſion implied by the words; but if time was rigorouſly beaten, in the manner the ancients have related, it is not very eaſy to ſubſcribe to this opinion.

Having explained the nature, difference, and properties of ancient rhythm, Dr. Burney beſtows a few words on an examination of the modern, and endeavours to ſhew what it has, in common with the ancient, and what peculiar to itſelf.

We no longer know rhythm now under its ancient name; however, it has been continued, with a ſmall change of pronunciation, merely to expreſs the final cadence of verſes, or the agreement and ſimilarity of ſound in the laſt ſyllables of two or more lines in poetry; being at preſent what we call *rhyme;* whereas the proportion ſubſiſting between the different parts of a melody are called *time*, *meaſure*, *movement.*

And when we come to examine this proportion, we find that it only conſiſts of two kinds, differently modified; and theſe two are known by the names of *common time*, conſiſting of equal numbers, and *triple time*, of unequal.

Tartini has deduced all meaſure from the proportions of the octave and its fifth. "Common time, or meaſure," ſays he, "ariſes from the octave, which is as 1 : 2; triple time ariſes from the fifth, which is as 2 : 3. Theſe," adds he, "are the utmoſt limits within which we can hope to find any practicable proportions for melody. Indeed many have attempted to introduce other kinds of meaſure, which, inſtead of good effects, have produced nothing but the greateſt confuſion; and this muſt always be the caſe. Muſic has been compoſed of five equal notes in a bar, but no muſician has yet been found that is able to execute it."

By the improvement of inſtrumental muſic, and indeed by the liberties which we have taken with poetry in ſinging, we have multiplied notes, and accelerated the meaſure. Inſtead of one ſound to one ſyllable, or one portion of time for a ſhort ſyllable, and two for a long one, we frequently divide and ſubdivide the time of theſe ſeveral portions into all their aliquot parts, and ſometimes into incommenſurable quantities.

After the invention of muſical characters for time, different from thoſe in poetry, the ſtudy of their relations became one of the moſt laborious and perplexed parts of a muſician's buſineſs. Theſe characters were of different value and velocity, according to other characters placed at the beginning of a muſical compoſition, and likewiſe frequently occurring in the courſe of a piece, to announce a change of meaſure; as from common time to triple, from quick to ſlow, or the contrary. Theſe characters were called *moods*, but they were ſo extremely embarraſſing and ill underſtood, till the invention of bars, by which muſical notes were divided into equal portions, that no two theoriſts agreed in the definition of them.

Theſe modes, by which the kind of movement, with reſpect to quick and ſlow, as well as the proportions of the notes, uſed to be known, ſince the uſe of technical terms, chiefly taken from the Italian language and muſic, has been adopted, ſerve no other purpoſe than to mark the number and kind of notes in each bar.

But by this invention of muſical characters for time, and the uſe of bars, we have certainly advanced in the performance of inſtrumental muſic, by giving to it more energy and accentuation; it has now a cadence and feet of its own, more marked and ſenſible than thoſe of poetry, by which it uſed to move.

We have alſo, in our *airs*, a diſtinct ſpecies of muſic for poetry, wholly different from recitative and chanting; for in theſe we are no more tied down to ſtated meaſure than the ancients, but are governed by the accent and cadence of the words. However, our florid-ſong, it cannot be diſſembled, is not always ſufficiently ſubſervient to poetry; for in applying muſic to words, it frequently happens that the fineſt ſentiments and moſt poliſhed verſes of modern languages are injured and rendered unintelligible, by an inattention to proſody. Even the ſimple and plain rules of giving a ſhort note to a ſhort ſyllable, a long to a long; and of accentuating the muſic by the meaſure and natural cadence of the verſe, which the mere reading would point out to a good ear and underſtanding, are but too frequently neglected.

Modern melody requires, perhaps, more than a ſingle ſound to a ſingle ſyllable; and a fine voice deſerves, now and then, a long note to diſplay its ſweetneſs; but this ſhould be done upon long ſyllables, and to open vowels, and, perhaps, in general, after the words have been once ſimply and articulately ſung, for the hearer to know what paſſion is intended to be expreſſed, or ſentiment enforced, by future diviſions.

Expletives, particles, and words of ſmall importance, are forced into notice by careleſs or ignorant compoſers, who, only intent upon mere muſic, pay no regard to her ſiſter, poetry. But then, poetry, in revenge, is as little ſolicitous about muſical effects; for ſymmetry of air, or ſimplicity of deſign, are generally ſo little thought of, that every heterogeneous idea, which can be hitched into rhyme, is indiſcriminately crowded into the ſame ſong. Indeed muſic and poetry, like man and wife, or other aſſociates, are beſt aſunder, if they cannot agree; and on many occaſions, it were to be wiſhed, that the partnerſhip were amicably diſſolved.

Salinas tells us, from St. Auguſtine, that poets and muſicians have ever been at ſtrife concerning long and ſhort ſyllables, accents, and quantity, ſince they have ceaſed to be united in one and the ſame perſon, and have ſet up different intereſts.

There is ſome poetry ſo replete with meaning, ſo philoſophical, fophical, inftructive, and fublime, that it becomes wholly enervated by being drawled out to a tune, which affects no part of the head, but the ear.

And there is, again, fome kind even of inftrumental mufic, fo divinely compofed, and fo expreffively performed, that it wants no words to explain its meaning; it is itfelf the language of the heart and of paffion, and fpeaks more to both in a few notes, than any other language compofed of clafhing confonants, and infipid vowels, can do in as many thoufand.

And, upon the whole, it feems as if poetry were more immediately the language of the head, and mufic that of the heart; or, in other words, as if poetry were the propereft vehicle of inftruction, and modulated found that of joy, forrow, and innocent pleafure. "Let the mufician," fays M. Rouffeau, "have as many images or fentiments to exprefs as you pleafe, with few fimple ideas; for the *paffions* only *fing*, the *underftanding fpeaks*."

But, notwithftanding both poetry and profody are fo frequently injured by injudicious compofers, it muft not be imagined that in our fimple airs of the gavot and minuet kind, we have no mufical rhythm, or that it always clafhes with the poetical. Innumerable inftances may be given from well-known Englifh fongs, where the cadence of the verfe, and even the pronunciation of each fyllable, is carefully preferved by the air. For though our time-table furnifhes fix different degrees of long and fhort notes, without points, yet, if the divifions in fongs defigned to difplay a particular talent for difficult execution be excepted, we feldom ufe more than *two* kinds of notes in the fame air.

"Mirth, admit me of thy crew," by Handel, as well as feveral popular fongs by Dr. Arne, Mr. Jackfon, and others, are fufficiently conformable to poetical numbers and rhythm, to fatisfy the greateft admirers of ancient fimplicity, or even fuch as love poetry better than mufic, from whom complaints of non-conformity generally proceed.

Ifaac Voffius fays it is now above a thoufand years fince muficians have loft that great power over the affections, which arofe only from the true fcience and ufe of rhythm; and he accufes modern mufic of fuch a want of time and accent, as to be all of one ftyle and colour. We will not defend the age in which Voffius wrote from the charge, nor the mufic of the prefent ferious opera in France; but the compofitions of Italy and Germany are certainly free from the cenfure, as mufic is now more divided into phrafes, and fentences, than it was; time is more marked, and more eafily felt than it has ever been fince the days of Guido. What it was before, is not very well known; but to confefs the truth, it is our opinion, that whatever it has comparatively loft in fome particulars, it has gained in others.

RHYTHMICA, Rhythmice, Ῥυθμικη, in the *Ancient Mufic*, that branch of mufic which regulated the rhythmus. See the preceding article.

RHYTHMOPŒIA, one of the mufical faculties, as they are called, which prefcribes rules for the motions, or rhythm.

The ancient rhythmopœia is very defective. We find nothing of it in the books of the ancients, but fome general hints, which can fcarcely be called rules. In their explications there appears nothing but what belongs to the words and verfes of their fongs, which is a ftrong prefumption they had no other. See Rhythm.

RHYTIDOSIS, formed of ῥυτιδοω, *to wrinkle*, the name of a diftemper of the eye, in which it waftes and wrinkles up.

RHYTIS, in *Botany*, from ῥυτις, *a channel*, or *furrow*, fo named by Loureiro, becaufe it has a furrowed berry.—Loureir. Cochinch. 660.—Clafs and order, *Polygamia Dioecia*. Nat. Ord. . . .

Gen. Ch. Perfect Flowers, *Cal.* Perianth inferior, cloven into from three to fix, obtufe, fpreading fegments. *Cor.* none. *Stam.* Filaments three, thread-fhaped, erect, longer than the calyx, attached to the receptacle; anthers two-lobed. *Pift.* Germen fuperior, rather long; ftyle none; ftigmas three, cloven, reflexed. *Peric.* Berry flatly ovate, rugofe, flaccid, with one cell, and three, ovate, fmall *feeds*.

Female Flowers on a feparate plant, *Cal.* Perianth inferior, cloven into numerous, lanceolate, hairy, fpreading fegments. *Cor.* none. *Stam* none. *Pift.* and *Peric.* as in the perfect flowers.

Eff. Ch. Calyx from three to fix-cleft. Corolla none. Stamens three. Stigmas three. Berry three-feeded.

Female, Calyx cloven into many fegments.

1. R. *fruticofa*. Shrubby Rhytis. Loureir. Cochinch. 660.—Native of woods in Cochinchina.—A *fhrub* about fix feet high. *Stem* nearly erect, branched in a fpreading manner. *Leaves* alternate, ovate-oblong, flightly pointed, fmooth, entire. *Flowers* in long, flender, crowded, terminal *fpikes*. *Berry* channelled.

RHYTIUM, in *Ancient Geography*, a town of the ifland of Crete.

RHYZELIUS, Andrew, in *Biography*, a learned Swedifh bifhop, was born in Weft Gothland in 1677, and ftudied at Upfal. In 1711 he was appointed profeffor of theology at Abo, from thence he proceeded to Upfal, where he was ordained, and appointed under paftor of the congregation of St. Nicholas at Stockholm. In 1713 he was nominated by Charles XII. to be one of his chaplains, whom he afterwards accompanied to Norway. He obtained other high offices, and at length, in 1743, he was raifed to the epifcopal bench. He died in the year 1761, leaving behind him a high character for deep learning and accurate judgment. His works are numerous, fome of which are, 1. "Svio-Gothica munita," or an hiftorical defcription of the towns, fortreffes, caftles, and royal palaces in the kingdoms of Sweden and Gothland. 2. "Monafteriologia Svio-Gothica," or a defcription of monafteries. 3. "Mnemonica Hiftoriæ Svio-Gothica Epitome." 4. "Epifcopofcopia Svio-Gothica," or a chronicle of the Swedifh bifhops. Gen. Biog.

RIAÇA, or Riaza, in *Geography*, a river of Spain, which rifes in the mountains which feparate Old and New Caftile, and runs into the Duero near Roa.

RIADHIAT, in *Modern Hiftory*, a fuperftitious practice among the Mahometans, and chiefly among thofe of Hindooftan, which confifts in fhutting themfelves up for fifteen days, without any other nourifhment than bread and water, in a place where there is no light; during which time, the devout Muffulman inceffantly repeats the word *hou*, which denotes one of the attributes of God.

RIAITTE', in *Geography*, a town of France, in the department of the Lower Loire, and chief place of a canton, in the diftrict of Ancenis; 12 miles N. of Ancenis. The place contains 613, and the canton 5555 inhabitants, on a territory of 150 kiliometres, in 5 communes.

RIAL, in *Commerce*. See Real.

Rial, or *Royal*, is alfo the name of a piece of gold anciently current among us for ten fhillings.

In 1 Henry VI. by indenture of the mint, a pound weight of gold of the old ftandard was coined into 45 rials, paffing for ten fhillings a-piece, or a proportional number of half rials, paffing at five fhillings a-piece; or rial farthings, which went at two fhillings and two-pence.

In

In 1 Henry VIII. the gold rial was ordered to pass at eleven shillings and three-pence. In 2 Elizabeth, gold rials were coined at fifteen shillings a-piece, when a pound weight of old standard gold was to be coined into 48 rials. In 3 James I. rose-rials of gold were coined at thirty shillings a-piece, and spur-rials at fifteen shillings.

RIALEJO, in *Geography*, a town on the W. coast of the island of Teneriffe.

RIALEJO, or *Ria Lexa*. See REALEJO.

RIALP, a town of Spain, in the province of Catalonia.

RIANA, in *Botany*, a genus of Aublet's; but that author gives no account, or reason, why it is so called. We presume this may be its common name in Guiana.—Aubl. Guian. 237. Juss. 287. Lamarck Illustr. t. 135.—Class and order, *Pentandria Monogynia*. Nat. Ord. *Berberides*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, cloven into five, roundish, acute segments. *Cor.* Petals five, ovate, acute, joined at the base. Nectary of five scales. *Stam.* Filaments five, very short, inserted at the base of the nectary; anthers ovate-oblong, nearly sessile, two-celled. *Pist.* Germen superior, ovate, villous, with five streaks; style fleshy; stigma capitate, obtuse. *Peric.* Capsule oblong, of one cell, and three valves, compressed in the middle. *Seeds* three.

Obs. Aublet describes the five-scaled nectary, as five inner petals.

Ess. Ch. Calyx deeply five-cleft. Petals five. Nectary composed of five scales. Anthers nearly sessile. Capsule of one cell and three valves. Seeds three.

1. R. *guianensis*. Aubl. Guian. t. 94.—Native of woods in Aroura, where it flowers in August. This *shrub* is ten feet high, and has a branched *trunk*. *Branches* erect, knobbed. *Leaves* opposite, stalked, ovate-oblong, acute, toothed, smooth, rigid. *Stipulas* short, twin, opposite, acute, deciduous. *Flowers* white, arranged in an alternate manner, forming a terminal *spike*; each flower on a short *stalk*, which has four scales or bracteas at the base.

Jussieu suspects that this plant may be akin to *Passoura*, Aubl. Guian. t. 380.

RIANANTLA, in *Geography*, a town of Mexico, in the province of Tlascala; 60 miles S. of Puebla de los Angelos.

RIANJO, a town of Spain, in Galicia, at the mouth of the Ulla; 23 miles S.W. of Compostella.

RIANO, a town of Italy, in the Patrimonio; 13 miles N. of Rome.—Also, a town of Naples, in Abruzzo Ultra; 8 miles W. of Teramo.

RIANS, a town of France, in the department of the Var; 10 miles N.W. of St. Maximin.

RIAO, an island in the East Indian sea, about 25 miles in circumference, near the W. coast of Morty. N. lat. 2° 25'. E. long. 128° 2'.

RIAPA CREEK, a river of West Florida, which runs into the Missisippi, N. lat. 31° 2'. W. long. 91° 17'.

RIAVIA, a mountain of Africa; 60 miles W. of Tripoli.

RIAZAN, a town of Russia, and capital of a government, on the Oka; 80 miles S.S.E. of Moscow. N. lat. 34° 45'. E. long. 38° 54'.

RIAZANSKOE, a government of Russia, bounded on the N. by Vladimirskoi, on the E. and S. by Tambovskoi, and on the W. by Moskovskaia and Talskoe; 108 miles from N. to S. and 100 from E. to W. N. lat. 54° 40' to 55° 20' E. long. 38° to 41°.

RIAZSK, a town of Russia, in the government of Riazan; 56 miles S.E. of Riazan. N. lat. 54°. E. long. 40° 4'.

RIB, in *Rural Economy*, the small arched bones forming the chests of animals. Cattle and most other animals should be full in the rib.

In horses the chest or barrel formed by the ribs should be full and circular, taking their fullness quite from the back-bone. See HORSE.

RIB-*Furrowing*, in *Agriculture*, a mode of ploughing somewhat similar to that of ribbling.

RIB-*Grass*, a sort of grass much cultivated in some districts, and which is said to afford an herbage of which cattle are very fond. It is also asserted to be useful as a grass for milch cows, and also for fattening any sort of stock. It is an indigenous plant in this country, which frequently abounds in pasture or meadow lands where the soil is rather inclined to moisture. See PLANTAGO.

In the mode of cultivating it as a grass for cattle food under the modern system of husbandry, from four to six pounds of seed are stated by Mr. Donaldson to be sown upon the acre. It is a coarse sort of grass, however, that requires to be kept well fed down, in order to render it valuable and prevent its running to seed.

In Cheshire some farmers are fond of it, while others think that its place would be better supplied by some of the other grasses. In some places, some fields are sown with it, nearly without any admixture of grass seeds; and where plentiful crops of it have been produced no animal would eat it, which is supposed probable from its nature. And in the Staffordshire agricultural report, it is said that there is authority for asserting that cattle will not eat its leaves, but it is believed to be grateful in admixture with other herbage.

RIBA, or RIBAS, in *Geography*, a town of Spain, in New Castile, on the Xaramo, founded by William de Ribas of Segovia, a celebrated commander, in the year 1100; 9 miles from Madrid.

RIBA *de Sella*, a small sea-port of Spain, in Asturia, on the coast of the Atlantic; 36 miles E.N.E. of Oviedo. N. lat. 43° 28'. W. long. 5° 18'.

RIBADAVIA, a town of Spain, in Galicia, famous for its vineyards, which are said to produce some of the best wine in Spain; 15 miles S.W. of Orense.

RIBADENEIRA, PETER, in *Biography*, a Spanish Jesuit, was a native of Toledo. He studied at Paris and at Padua, after which he taught rhetoric with reputation at Palermo. He died at Madrid in 1611, aged 81. His works are "Lives of the Saints," folio, 1616; the "Lives of St. Ignatius Loyola, St. Francis de Borgia, and of the Father Lainez and Solmeron;" "A Treatise of the Schism of England;" another entitled "The Prince," which is full of bad political maxims; and the "Library of Writers among the Jesuits," 8vo.

RIBADEO, in *Geography*, a sea-port town of Spain, in Galicia, at the mouth of the Eo, with a good harbour defended by two castles; 15 miles N.E. of Mondonedo. N. lat. 43° 33'. W. long. 7° 5'.

RIBAGNAC, a town of France, in the department of the Dordogne; 5 miles S. of Bergerac.

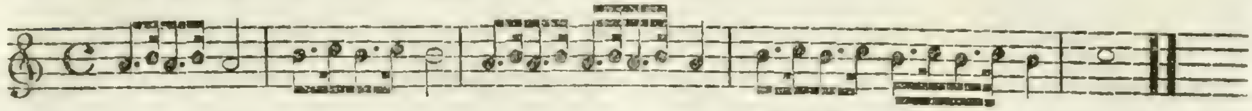
RIBAGORZA, a district of Spain, bordering on the E. part of Aragon, and W. part of Catalonia; watered by the river Noguera de Ribagorza, about 40 miles long and 18 wide, N. of Balaguers.

RIBAN, an island in the Red sea, near the coast of Arabia. N. lat. 17° 12'.

RIBAT-

RIBATTUTA, Ital. in *Muſic*, is iterating, ſtriking, or ſounding the ſame note again.

Ribattuta *di Gola* is one of the graces uſed in ſinging; it is performed by beating or ſtriking two diatonic notes, the one ſlow and the other quick, in the following manner.



It differs from the ſhake and the beat.

RIBAUDEQUEM, in *Ancient Artillery*, a projectile machine uſed in the 11th and 12th centuries, which was a large kind of croſs-bow: the croſs-bow was called in Latin baliſta, and ſometimes manubaliſta.

RIBAUVILLE', in *Geography*, a town of France, in the department of the Upper Rhine, and chief place of a canton, in the diſtrict of Colmar; 6 miles N. of Colmar. The place contains 4950, and the canton 14,219 inhabitants, on a territory of 85 kiliometres, in 9 communes.

RIBBAND, or Ribbond, a narrow ſort of ſilk, chiefly uſed for head ornaments, badges of chivalry, &c.

The knights of the Garter wear a blue ribband; thoſe of the Thiſtle, a green ribband, &c. ſcarfwiſe. See Collar, Garter, &c.

Ribbands, *Figured.* See Figured.

Ribband, or *Ribbon*, in *Heraldry*, is the eighth part of a bend. (See the article Bend.) It is borne a little cut off from the outlines of the eſcutcheon: thus; he beareth or, a ribband, gules.

Ribbands, from *rib* and *band*, in *Ship Building*, are long pieces of fir timber from four to eight inches ſquare, according to the ſize of the ſhip; theſe are nailed on at certain heights to the frame timbers of the ſquare body, as the *harpins*, which are oak of the ſame ſize, are nailed to the frames of the cant-bodies; but the latter are ſhaped to the form of the body by moulds and bevelling. The ends of the harpins forward are faſtened againſt the ſtem, and thoſe abaſt againſt the ſtern-poſt or tranſoms; the ribbands then uniting with the harpins, envelop the ſhip lengthways, and being judiciouſly arranged, with regard to their diſtance from each other, they not only ſupport the filling-timbers, but by being ſhored at every frame, the whole ſhip is ſupported, and kept to her true ſhape, until the plank is brought on, as they are in that caſe removed one at the time, the bottom being ſhored againſt the planks above. The difference between cant-ribbands and horizontal or ſquare ribbands is, that the latter are only ideal, and uſed in the laying-off.

RIBBING Nails. See Nail.

RIBBLE, in *Geography*, a river of Lancaſhire, England, has its ſource in the high moors of Craven, Yorkſhire, and paſſing the lofty mountains of Ingleborough and Pennigaut, enters the county of Lancaſter near the town of Clitherhoe, where it forms a boundary to the county. Taking a ſouth-weſtern courſe, and receiving, in its progreſs through Lancaſhire, ſeveral ſmaller ſtreams, and the tributary rivers of the Hodder, Calder, and Darwent, it paſſes by Ribcheſter and Preſton. Soon after leaving the latter town it gradually expands its ſtream, and in a few miles preſents a broad eſtuary, and unites its waters with the Iriſh ſea. At this place, the ferry from North Theols to Lytham, it is about five miles acroſs at high water. This river is navigable, for ſmall coaſters, as high as Preſton, and was formerly capable of conveying veſſels much higher up the country. At Preſton it is croſſed by an aqueduct, for the Lancaſter canal. See Aiton's Lancaſhire Gazetteer, Beauties of England, vol. ix. and Whitaker's Hiſtory, &c. of Whalley, 4to.

RIBBLING, in *Agriculture*, a term uſed in ſome diſtricts to ſignify a mode of ploughing ſimilar to that of ſlob-furrowing. It is practiſed in ſome northern counties as well as thoſe of the ſouth, and in the former appears to be the only kind of winter fallow which is beneficial to lands of looſe texture. Every furrow that is turned over on a foot of ſolid ground, from the beginning to the end of the ridge, that is every alternate furrow, is left untouched, and the ploughed furrow is turned over above it, ſo that the greateſt ſurface poſſible is expoſed to the ameliorating influence of the atmoſphere, while, at the ſame time, the looſe ſoil is out of the reach of any little rills which may run down in the different ruts. If the ſtubble has been, in ſome meaſure, luxuriant, and the ribbling done ſoon after the crop was taken from the ground, the two ſtrata of ſtubbles meeting and fermenting under cover of the rid furrow, form, it is ſuppoſed, an aid to the ſubſequent manure, while the weeds are no leſs ſmothered than when the whole land is turned over by a complete ploughing. Neverthleſs, it is believed, that when the uſe of green crops becomes general, and the planting and hoeing of them are neatly performed by the plough, this will ſtir the earth more perfectly, and pulverize and clean the ſoil more completely than any winter fallow or ribbling can poſſibly effect. See Tillage.

RIBCHESTER, in *Geography*, a village and pariſh in the hundred of Blackburn, and county palatine of Lancaſter, England, is ſituated at the diſtance of five miles and a half N.N.W. from the town of Blackburn, and eight miles N.E. from Preſton. Though now comparatively an inſignificant place, it was in Roman times an important and flouriſhing town. Much diſpute has taken place among antiquaries with reſpect to the original name of this ſtation. Horſley calls it the Coccium of Antoninus, and Camden the Rigodunum of Ptolemy, the identity of which places is clearly proved by the reaſonings of Dr. Whitaker, in his Hiſtory of Whalley. (See Coccium, in which article for *Rilcheſter* read *Ribcheſter*.) Mr. Whitaker, the author of the Hiſtory of Mancheſter, however, contends that Ribcheſter muſt have been the Rerigonium of Richard of Cirenceſter, and places Coccium at Blackrode. But whatever was the name of this place, it was indubitably among the number of Agricola's ſtations, and appears to have been not merely a military poſt, but the ſeat of manufacturing and commercial proſperity. At that period the river Ribble was navigable as high as Coccium to veſſels of no inconſiderable burden. Of this fact, tradition, the veſtiges of a dock, and numerous nautical relics, afford inconteſtible proof. To the filling up of the river, by the gradual accumulation of ſand, is to be attributed, in part at leaſt, the decay of this place after its abandonment by the Romans. Many votive ſtones, and others with inſcriptions, have been found here. Of theſe Dr. Whitaker has printed nine, but they do not furniſh any thing intereſting either with reſpect to the place or the people. Various ſmaller antiquities have likewiſe been dug up here at different periods; ſuch as ſilver and braſs coins, an intaglio in a ruby, gold rings, &c. "But," to uſe the words of the hiſtorian of Whalley, "the nobleſt diſcovery ever made here, or perhaps in Britain, was in the year 1796, when the ſhelving bank of the Ribble expoſed the following remains, which ſeemed to have been depoſited in an excavation of the earth, filled up with ſoil of a different quality. Theſe were,

were, 1. A large flat earthen veſſel, extremely thick, with the potter's ſtamp very diſtinct, "Boriedof, *Boriedi officina.*" 2. An entire patera of copper, about ſix inches diameter, with a handle. 3. The imperfect remains of a ſimilar veſſel. 4. A column, or colander of the ſame ſize and metal. 5. Several concave and circular plates of copper, with loops behind, which had evidently been intended to faſten them perpendicularly againſt a ſhaft, in order to form a Roman vexillum: ſuch are frequent upon ancient monuments; but for a particular illuſtration, the reader is referred to a monument of Lucius Duccius, ſignifer of the ninth legion, in Horſley, pl. 63. 6. A very fine helmet, of which the creſt was a ſphinx, afterwards unfortunately loſt, the head-piece enriched with baſſo relievos of armed men ſkirmiſhing with ſwords, and a viſor, conſiſting of an entire and beautiful female face, with orifices at the eyes, mouth, and noſtrils." Theſe remains were depoſited in the muſeum of Charles Townley, eſq. The helmet particularly merits attention. From the ſtyle of the head-piece, it is conjectured by the beſt judges not to be prior to the age of Severus; but the viſor is a much more delicate and exquiſite piece of workmanſhip, and is ſuppoſed not only to be Grecian, but, from the boldneſs of its lines, to belong to a period ſomewhat anterior to the laſt perfection of the arts in that wonderful country. For engraving of this helmet, with ſome obſervations thereon, ſee "Vetuſta Monumenta," vol. iv.

The chief remains of this ſtation, now viſible, are a mutilated rampart and foſſe, ſurrounding a ſmall eminence near the church, which is called Anchor-hill, from the circumſtance of ſeveral anchors having been dug up at its baſe. In the ſame place, ſome years ago, an entire veſſel was diſcovered at a great depth beneath the ſurface of the ground. From this place the Roman road, called Watling-ſtreet, ſtretches itſelf in a northern direction over Long Ridge Fell, marked by "a long ſtripe of green interſecting the brown heath of the mountain." Hence it is denominated Green Lane. It enters Yorkſhire a little below Dowford bridge, and proceeds by Newton and Bentham to the celebrated ſtation at Overborough.

The pariſh of Ribcheſter formerly conſtituted a portion of the original pariſh of Whalley, but was ſevered from it at the ſame time with that of Chipping. According to the parliamentary returns of 1811, it contained 649 houſes, and 3544 inhabitants, including the townſhips of Ribcheſter, Dilworth, Dutton, Alſton, and Hotherſal.

At Stede, in the vicinity of Ribcheſter, is a parochial chapel, which Dr. Whitaker ſtates to be the oldeſt building within the boundaries of ancient Whalley. It appears to have formerly belonged to a guild, or hoſpital, and, from the ſtyle of its architecture, was probably erected in the reign of king Stephen. The arches are ſlightly pointed, and are decorated with zigzag, and other Saxon ornaments. In the interior is a "coffin tomb" of high antiquity, placed in front of the pulpit, which is elevated upon an antique ſtone pediment. The floor is covered with ancient grave ſtones, ſome of which are inſcribed with Longobardic or Norman characters. An Hiſtory of the original Pariſh of Whalley and Honor of Clitheroe, in the Counties of Lancaſter and York, by Thomas Dunham Whitaker, L. L. D., F. S. A. 2d edit. 4to. Lond. 1806. A Deſcription of the Country, from thirty to forty Miles round Mancheſter, by J. Aikin, M.D. 4to. Lond. 1795. Hiſtory of Mancheſter, by John Whitaker, B. D., F. S. A. 2. vols. 4to. 1771. Antiquitates Bremetonacenſes; or the Roman Antiquities of Overborough, &c. Lond. 4to. 1746.

RIBECOURT, a town of France, in the department of the Oiſe, and chief place of a canton, in the diſtrict of Compiegne. The place contains 520, and the canton 8805 inhabitants, on a territory of 182½ kiliometres, in 21 communes.

RIBEMONT, a town of France, in the department of the Aiſne, on the Oiſe, and chief place of a canton, in the diſtrict of St. Quentin; ſix miles S.E. of St. Quentin. The place contains 2345, and the canton 12,497 inhabitants, on a territory of 182½ kiliometres, in 17 communes.

RIBENSKOI, a town of Ruſſia, on the Tunguſka; 72 miles E.S.E. of Eniſeiſk.

RIBERA, Francis de, in *Biography*, a learned Spaniſh Jeſuit in the ſixteenth century, was born in the year 1537. He purſued his academical ſtudies at the univerſity of Salamanca, and acquired a high reputation for his intimate acquaintance, not only with the Latin, but with the learned languages alſo. Having been ordained prieſt, he retired to his native place, that he might proſecute his theological ſtudies in uninterrupted privacy, at the ſame time he was able to aſſiſt his brethren in the neighbouring country churches. In the year 1570, when he was thirty-three years of age, he was perſuaded to unite himſelf with the diſciples of Loyola, and become a member of their ſociety. He now ſpent moſt of his time in interpreting the ſcriptures, and filling the chair of profeſſor of divinity, in their ſeminary at Salamanca, till his death, which happened in the year 1591. He was author of numerous works, which are ſtill in eſtimation with the Catholics; among theſe may be mentioned "Commentarii in XII. Prophetas minores, ſenſum eorundem Prophetarum hiſtoricum et moralem, ſæpe etiam Allegoricum complectentes," 4to. "Commentarii Hiſtorici ſelecti in XII. Prophetas minores," 8vo. "De Templo, et iis quæ ad Templum pertinent Lib. V." 8vo. And "The Life of St. Thereſa, Foundreſs of the reformed Order of the barefooted Carmelites," written in the Spaniſh language.

Ribera, Giuseppe. See Spagnoletto.

Ribera, in *Geography*. See *St.* Jago.

Ribera *de Muria*, a town of Portugal, in Eſtramadura; ſix miles N. of Thomar.

RIBERAC, a town of France, and chief place of a diſtrict, in the department of the Dordogne; 17 miles E. of Perigueux. The place contains 2985, and the canton 11,194 inhabitants, on a territory of 85 kiliometres, in 13 communes. N. lat. 45° 14′. E. long. 6° 25′.

RIBERAIRY, a town of Abyſſinia; 25 miles E.N.E. of Axum.

RIBES, in *Botany*, an Arabian name, properly belonging to an acid-leaved ſpecies of Rheum, ſee that article; but which botaniſts, for about 200 years paſt, have, by miſtake, applied to the currant and gooſeberry family, and with theſe it now remains. They conſtitute a natural and very important genus.—Linn. Gen. 111. Schreb. 154. Willd. Sp. Pl. v. 1. 1153. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 263. Prodr. Fl. Græc. Sibth. v. 1. 160. Ait. Hort. Kew. v. 2. 40. Purſh 163. Juſſ. 310. Lamarck Illuſtr. t. 146. (Groſſularia; Tourn. t. 409. Gærtn. t. 28.) —Claſs and order, *Pentandria Monogynia*. Nat. Ord. *Pomaceæ*, Linn. *Cacti*, Juſſ.

Gen. Ch. *Cal.* Perianth ſuperior, of one leaf, tubular, or bell-ſhaped; the limb cut, about half way down, into five oblong, concave, coloured, reflexed, permanent ſegments. *Cor.* Petals five, ſmall, obtuſe, erect, inſerted into the rim of the calyx. *Stam.* Filaments five, awl-ſhaped, erect, inſerted into the rim of the calyx; anthers incumbent, compreſſed, burſting at the edges. *Piſt.* Germen roundiſh, inferior; ſtyle cloven; ſtigmas obtuſe. *Peric.* Berry globoſe, umbilicated, of one cell, with two lateral, oppoſite, longitudinal

tudinal receptacles. *Seeds* numerous, roundifh, flightly compreffed.

Eff. Ch. Calyx fuperior, tubular, five-cleft. Petals inferted, with the ftamens, into the calyx. Style cloven. Berry with many feeds.

The whole genus is fhrubby. *Leaves* deciduous, alternate, ftalked, fimple, lobed and notched. *Flowers* ftalked, generally pale, greenifh or yellow, rarely reddifh. *Fruit* eatable.

Section 1. Currants. *Stem without prickles.*

1. R. *rubrum.* Common Currant. Linn. Sp. Pl. 290. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 1289. Woodv. Med. Bot. t. 74. Fl. Dan. t. 967. (R. vulgaris, fructu rubro; Ger. Em. 1593.)—Clufters fmooth, pendulous. Flowers flattifh. Petals inverfely heart-fhaped. Leaves obtufely five-lobed. Stem erect.—Native of woods and thickets, efpecially about the banks of rivers, in the north of Europe. Undoubtedly wild on the banks of the Tees, Durham. *Mr. Robfon.* Commonly cultivated throughout the cooler parts of Europe, for the fake of its gratefully acid and wholefome berries, of which the white or blufh variety is the fweeteft and mildeft. It flowers in May; the fruit is fcarcely ripe before Auguft. The *ftem* is bufhy, three or four feet high, or more, if trained to a wall, with fmooth blackifh bark. *Leaves* on long ftalks, fpreading, doubly ferrated, veiny, bright green, fomewhat downy. *Flowers* in ftalked, fimple, pale green, drooping clufters. *Petals* yellowifh-green. *Bracteas* ovate, minute, folitary at the bafe of each partial flower-ftalk. *Fruit* quite pendulous.

2. R. *petræum.* Rock Currant. Wulf. in Jacq. Mifc. v. 2. 36. Jacq. Ic. Rar. t. 49. Willd. n. 2. Fl. Brit. n. 4. Engl. Bot. t. 705. (R. n. 818; Hall. Hift. v. 1. 364. R. vulgaris rubro flore; Cluf. Hift. v. 1. 119.)—Clufters erect, fomewhat hairy; pendulous when in fruit. Flowers flattifh. Petals obtufe. Leaves acutely lobed. Bracteas fhorter than the flower-ftalks. Stem erect.—Native of Germany, Switzerland, and the north of England. This was confounded, even by Haller, with the former. The *leaves* are more downy, efpecially about the veins; more acutely lobed and notched. *Clufters* erect when in bloffom; their ftalks lefs elongated in the lower part. *Flowers* often ftained with red. *Berries* bright red, very acid.

3. R. *fpicatum.* Acid Mountain Currant. Robfon Tr. of Linn. Soc. v. 3. 240. t. 21. Fl. Brit. n. 3. Ait. n. 6. Engl. Bot. t. 1290.—Spikes erect. Flowers nearly feffile. Petals oblong. Bracteas fhorter than the calyx. Stem erect.—Native of the mountainous parts of Yorkfhire and Durham, flowering in May. Differs from the laft in having the *inflorefcence* fpiked, not racemofe; upright both in flower and fruit. The *berries* are red and acid.

4. R. *procumbens.* Trailing Currant. Pall. Roff. v. 1. p. 2. 35. t. 65. Willd. n. 3. Ait n. 3.—Clufters erect. Flowers flattifh. Leaves bluntly lobed. Berries fmooth. Stem procumbent. Plentiful, according to Pallas, on the moffy fides of hills in Dauria, where its fruit is much in requeft. The proftrate *ftems* are concealed among the mofs. *Leaves* not bigger than thofe of a goofeberry-bufh, while the fhrub is in bloffom, but afterwards attaining the fize and fhape of the three foregoing fpecies. *Flowers* like *R. rubrum*, but fmaller, in erect *clufters*, which become drooping as the fruit ripens. The *berries* are full as large as a common Black Currant, but of a greenifh-yellow, or, when quite ripe, reddifh.

5. R. *glandulofum.* Glandulous Currant. Ait. n. 4. Willd. n. 4. (R. proftratum; L'Herit. Stirp. v. 1. 3. t. 2. Purfh n. 4.)—Clufters erect, rough with glandular hairs. Flowers flattifh. Leaves acutely lobed, toothed. Bracteas minute. Berries hifpid. Stem creeping, with afcending branches.—Native of rocky moift places, in Newfoundland, Canada, and Pennfylvania, flowering in April and May. *Purfh.* Habit and *leaves* not unlike the laft. The *flowers* are yellow, tinged with red. *Berries* red.

6. R. *rigens.* Stiff-branched Currant. Michaux Boreal-Amer. v. 1. 110. Purfh n. 3.—Clufters lax, erect. Leaves acutely lobed and toothed, reticulated, rugofe; downy beneath. Berries roughifh. Branches ftraight.—On the banks of lake Miftaffins, in Canada. *Michaux.* In the Pennfylvanian mountains, &c. flowering in May and June. *Berries* red, erect, as well as the *flowers*. *Purfh.*

7. R. *trifidum.* Notched-flowered Currant. Michaux Boreal-Amer. v. 1. 110. Purfh n. 2.—Clufters lax, downy. Leaves lobed, fmooth; downy beneath. Flowers flattifh. Segments of the calyx flightly three-cleft. Petals fpatulate. Berries hairy.—Found by Michaux near Quebec, and at Hudfon's Bay; by Purfh on the Pennfylvanian mountains, &c. flowering in April and May. *Flowers* like *R. rubrum*, but fmaller. *Calyx* pale green. *Petals* purple, rounded, and blunt at the end. *Berries* red.

8. R. *albinerve.* White-veined Currant. Michaux Boreal-Amer. v. 1. 110. Purfh n. 1.—Clufters recurved. Berries fmooth. Leaves fhort, acutely lobed, fmoothifh, with pale ribs.—Found by Michaux, about lake Miftaffins, Canada; by Purfh, on the Catfkill mountains, about New York, &c. flowering in April and May. *Flowers* fmall, greenifh-yellow. *Berries* red.

9. R. *alpinum.* Taftelefs Mountain Currant. Linn. Sp. Pl. 291. Willd. n. 5. Fl. Brit. n. 2. Engl. Bot. t. 704. Jacq. Auftr. t. 47. Fl. Dan. t. 968.—Clufters erect. Bracteas longer than the flowers. Leaves fmooth; fhining at the back. Stem erect. Berries fmooth.—Native of mountainous woods and thickets, in Germany, Switzerland, Sweden, Siberia, and the north of England, flowering in April and May. The *leaves* are rounder, and fcarcely half fo large as thofe of our common Currants, befides being quite fmooth on both fides, and remarkably polifhed beneath. *Bracteas* very long, acute, erect. *Flowers* faid to be often dioecious, from which caufe perhaps the *fruit* is feldom perfected in our fhrubberies, where this fpecies often occurs. The *berries* are fomewhat elliptical, of a beautiful red, but infipid and mucilaginous like a folution of gum arabic.

10. R. *refinofum.* Refinous Currant. Purfh n. 5. Curt. Mag. t. 1583.—Whole plant vifcid, with glandular hairs. Leaves with roundifh, notched lobes. Clufters erect. Flowers flattifh. Bracteas tongue-fhaped, concave, as long as the flowers. Berries hairy.—Gathered on the mountains of North America, by Mr. Frafer, from whofe garden we obtained flowering fpecimens, in May 1810. This has more the afpect of a goofeberry-bufh, efpecially in the fize and form of the *leaves*, but the whole herbage is clothed with downy, vifcid, fœtid pubefcence. *Clufters* moft like thofe of *R. alpinum*, but the partial *flower-ftalks* are extremely fhort, and the *bracteas* more obtufe, and elliptical. *Flowers* apparently dioecious, green, with fhort, rounded, yellowifh *petals*.

11. R. *vifcofiffimum.* Glutinous Currant. Purfh n. 6. —Whole plant very glutinous, with vifcid hairs. Leaves heart-fhaped, bluntly three-lobed, ferrated. Clufters fhort, erect. Calyx tubular. Petals oblong. Bracteas linear-fpatulate, fhorter than the partial flower-ftalks. Germen hairy.—Found by the late governor Lewis, on rocky mountains in the interior of North America, flowering in June.

June. Whole plant covered with viſcous hair. *Flowers* large, yellow. This approaches near to *R. glanduloſum*, Fl. Peruv. v. 3. 13. t. 233. f. *b.* It differs principally in the *leaves* being equally lobed, not having the middle lobe projecting; its long ſlender *partial flower-ſtalks*, and its *petals*. *Purſh.*

12. R. *ſanguineum.* Crimſon-flowered Currant. Purſh n. 7.—Leaves heart-ſhaped, three-lobed, ſerrated, veiny; ſmooth above; finely downy and hoary beneath. Cluſters lax, downy, twice the length of the leaves. Calyx tubular. Petals oblong, equal to the limb. Bracteas obovate-ſpatulate, the length of the partial ſtalks. Germen hairy.—Gathered by governor Lewis, on the Columbia river, flowering in March. *Branches* purple. *Flowers* beautiful, blood-red or purple. It nearly approaches *R. albinervium*, Fl. Peruv. v. 3. 12. t. 232. f. *b.* *Purſh.*

13. R. *malvaceum.* Mallow-leaved Currant.—Leaves heart-ſhaped, ſlightly five-lobed, ſerrated, veiny; hiſpid on both ſides; denſely downy beneath. Cluſters hairy, longer than the leaves. Calyx tubular, hairy. Petals rounded, not half ſo long as the limb. Bracteas ovate, acute, jagged, half the length of the calyx.—Gathered in California, by Mr. Menzies. *Branches* dark purple, downy, like every part of the plant. *Leaves* an inch, or inch and half, long; dark green above; white, and denſely downy, beneath; hiſpid on both ſides with glandular briſtles. *Stipulas* beautifully fringed. *Cluſters* denſe, on long, rough, glandular *ſtalks.* *Calyx* red, about half an inch long, hairy, eſpecially its baſe, and the *germen.* *Petals* wedge-ſhaped, rounded, ſomewhat cloven, ſcarcely one-third ſo long as the ſegments of the limb, which are elliptical. *Stamens* the length of the petals. *Bracteas* elegantly jagged and fringed. This fine ſpecies ſeems nearly allied to the laſt. We have not at hand the *Flora Peruviana*, to aſcertain how far it reſembles any in that work.

14. R. *aureum.* Golden-flowered Currant. Purſh n. 8.—Very ſmooth. Leaves with three, obtuſe, ſparingly notched lobes. Footſtalks fringed at the baſe. Cluſters denſe. Calyx tubular, ſlender. Petals linear, half the length of the limb. Bracteas linear, equal to the partial ſtalks. Berry ſmooth.—Found by governor Lewis on the banks of the Miſſouri and Columbia, flowering in April. We received wild ſpecimens from Mr. John Bradbury, three years ago. The *leaves* have the aſpect of Hawthorn. *Flowers* in denſe cluſters. *Calyx* of a beautiful golden yellow, about three-fourths of an inch long, not unlike the flower of a Jonquill in miniature, and reported to have a ſimilar ſcent; its ſegments oblong, obtuſe. *Petals* purple. *Berries* red or brown, conſiderably larger than any garden currants, and peculiarly delicious in flavour. This very deſirable plant is introduced into the gardens about London, but we have not yet heard of its bloſſoming.

15. R. *recurvatum.* Recurve-branched Currant. Michaux Boreal-Amer. v. 1. 109. Purſh n. 9.—"Branches recurved. Leaves dilated, downy, dotted with minute glands, acutely lobed. Cluſters reflexed. Calyx tubular, ſmooth."—Found near Hudſon's Bay. *Michaux.* *Berries* black. We know nothing more of this ſpecies.

16. R. *fragrans.* Fragrant Siberian Currant. "Pallas Nov. Act. Acad. Petrop. v. 10. 377. t. 9." Willd. n. 6.—Stem aſcending. Leaves bluntly three-lobed, glandular beneath.—Flowers bell-ſhaped. Cluſters erect.—Native of Siberia, on mountains bordering on the country of the Mongols, where no woods grow. The *ſtems* are partly procumbent, a foot and a half long; their young *branches* beſprinkled with yellow, prominent, glandular dots. *Leaves* on long ſtalks, ſmooth, ſerrated, ſlightly five-angled, with three or five lobes; very veiny, and moſt glaucous beneath, where alſo they are covered with minute crowded drops of a yellow fragrant exudation, having a ſcent ſtronger than balm, approaching that of *R. nigrum*, n. 18, to which ſpecies indeed the preſent bears altogether a conſiderable reſemblance. *Cluſters* when in flower ſhort, erect, rigid, denſe, of about ten white, highly fragrant, *flowers.* *Calyx* bell-ſhaped, deeply five-cleft. *Petals* lanceolate, acute, ſpreading. *Bracteas* deciduous, ſmaller than in *R. procumbens*, n. 4. *Cluſters* elongated in fruit, ſtill erect, except when bent down by its weight. *Berries* reddiſh, extremely ſweet, the full ſize of *R. rubrum.* *Pallas.*

17. R. *triſte.* Dark-coloured Siberian Currant. "Pallas Nov. Act. Acad. Petrop. v. 10. 378." Willd. n. 7.—Root creeping. Stems erect, leafy in the upper part. Leaves five-lobed. Cluſters ſmooth, pendulous. Flowers flattiſh. Petals revolute.—Native of lofty mountains in Siberia, towards Tartary. The creeping *root* throws up many erect *ſtems*, two or three feet high, bearing at their ſummits a few ſcattered *leaves*, reſembling thoſe of *R. rubrum.* *Cluſters* always pendulous. *Flowers* reddiſh without, yellowiſh within. *Berries* ſmall, black, inſipid; their deep-red juice very uſeful for colouring wines. *Pallas.*

18. R. *nigrum.* Common Black Currant. Linn. Sp. Pl. 291. Willd. n. 8. Fl. Brit. n. 5. Engl. Bot. t. 1291. Woodv. Med. Bot. t. 75. Fl. Dan. t. 556. Lob. Ic. v. 2. 202.—Stem erect. Leaves five-lobed, acute. Cluſters pendulous, downy, with a ſeparate flower-ſtalk at their baſe. Calyx tubular-bell-ſhaped. Berries ſmooth.—Native of wet buſhy iſlands, and banks of rivers, in Sweden, Germany, Switzerland, and England; flowering in May. In gardens it is well known, and valued for the fruit, whoſe flavour indeed, in a recent ſtate, is not acceptable to every body; but its jelly is both agreeable, and uſeful for colds, ſore-throats, &c.; whence this currant has been named Squinancy-berry or Quinſy-berry. The buſh is of a more humble ſtature than *R. rubrum*; the *leaves* have a ſtrong ſcent, if bruiſed, reſembling Savine, and are ſomewhat glutinous when young. The tube of the *calyx* is more elongated than in any other Britiſh ſpecies. *Berries* large, black, each bunch always accompanied at the baſe by a ſolitary ſtalk, whoſe fruit is larger and earlier than the reſt. Dr. Withering made the truly curious obſervation, that the *petals* are ſometimes changed into *ſtamens*, of which we know no other inſtance.

19. R. *floridum.* Penſylvanian Black Currant. L'Herit. Stirp. v. 1. 4. Willd. n. 9. Ait. n. 8. Purſh n. 10. (Ribeſium nigrum penſylvanicum, floribus oblongis; Dill. Elth. 324. t. 244. f. 315.)—Leaves three-lobed, cut; dotted with glands on both ſides. Cluſters pendulous, downy. Calyx ſomewhat cylindrical. Bracteas about as long as the germen.—Found in hedges and woods, from Canada to Virginia; flowering in April and May. *Flowers* pale yellow. *Berries* black. *Purſh.* The reſinous dots on both ſides of the *leaves* diſtinguiſh this ſpecies, and its *flowers* are more oblong than thoſe of *nigrum*, with much larger *bracteas.*

Sect. 2. Gooſeberries. *Stem prickly.*

20. R. *Diacantha.* Two-thorned Cluſter Gooſeberry. Pallas Reiſe v. 3. 722. t. I. f. 2. Roſſ. v. 1. p. 2. 36. t. 66. Linn. Suppl. 157. Willd. n. 10. Ait. n. 9.—Prickles in pairs, in the place of ſtipulas. Leaves wedge-ſhaped, deeply three-cleft, bluntly notched. Cluſters nearly erect. Berries ſmooth.—Native of gravelly, ſtony, ſaline ſoils in Dauria. Introduced into England by Mr. Buſh, in 1781. Hardy, flowering in May and June. *Ait.* Linnæus ſays it flowered every year at Upſal, without bearing fruit.

fruit. Poſſibly the *flowers* may be in ſome meaſure dioecious, like thoſe of *R. alpinum*, a ſpecies which this nearly reſembles, except the prickles.

21. R. *ſaxatile*. Rock Siberian Gooſeberry. "Pallas Nov. Act. Acad. Petrop. v. 10. 376." Willd. n. 11.—Prickles ſcattered, ſetaceous. Leaves wedge-ſhaped, bluntly three-lobed. Cluſters erect.—Native of granite mountains in Siberia. Allied to *R. alpinum* and *R. Diacantha*. *Berries* red, ſouriſh, ſcarcely ſo big as our red currant. *Pallas*.

22. R. *reclinatum*. Procumbent Gooſeberry. Linn. Sp. Pl. 291. Willd. n. 12. Ait. n. 10.—Prickles ſolitary or three together. Branches reclining. Stalks ſingle-flowered, with a three-leaved bractea. Germen hairy.—Native of Germany and Switzerland. Said to have been long known in our gardens. It much reſembles the following.

23. R. *Groſſularia*. Rough Gooſeberry. Linn. Sp. Pl. 291. Willd. n. 13. Ait. n. 11. Fl. Brit. n. 6. Engl. Bot. t. 1292. (R. Uva criſpa; Fl. Dan. t. 546.)—Prickles ſolitary or three together. Branches ſpreading. Footſtalks hairy. Stalks ſingle-flowered, with a two-leaved bractea. Fruit hairy.—Common throughout Europe, but ſo generally cultivated, that we can hardly ſay when we meet with it truly wild. The *ſhrub* is buſhy, of humble growth, armed, as every body knows, with ſmooth awl-ſhaped prickles, either ſolitary or ternate, in the place of *ſtipulas*. *Leaves* bluntly three-lobed and cut, ſlightly downy. *Flowers* drooping, ſolitary, green, on downy ſtalks, with two ſeparate *bracteas*. *Calyx* cup-ſhaped. *Germen* and *fruit* rough with prominent briſtly hairs. The *berries* are either green, yellow, or red.

24. R. *Uva criſpa*. Smooth Gooſeberry. Linn. Sp. Pl. 292. Willd. n. 14. Ait. n. 12. Fl. Brit. n. 7. Engl. Bot. t. 2057. Schmidel Ic. 5. t. 1. (Uva criſpa; Fuchſ. Hiſt. 187. Ger. Em. 1324.)—Prickles uſually three together. Branches ſpreading. Footſtalks hairy. Stalks ſingle-flowered. Bracteas united into a tube. Fruit ſmooth.—Native of Europe, and as commonly cultivated as the laſt, of which we believe it a mere variety. The number and connection of the *bracteas* are certainly variable.

25. R. *aciculare*. Needle Siberian Gooſeberry.—Prickles ſcattered, ſetaceous; thoſe under the buds five together, combined. Leaves bluntly five-lobed and cut. Stalks ſingle-flowered. Bracteas united. Fruit ſmooth.—Gathered by Laxmann in Siberia. We find two ſpecimens in the Linnæan herbarium of this, which ſeems a very diſtinct ſpecies, hitherto neglected by every author. The habit is like the three laſt, but the *branches* are copiouſly armed all over with fine, ſtraight, prominent, needle-like, brown *prickles*, beſides the larger ones, five together, and combined by a broad baſe, which ſtand, like thoſe of common Gooſeberries, under the buds. *Flowers* ſolitary, drooping, on longiſh ſimple ſtalks, with two or three *bracteas*, uſually combined, about the middle. *Calyx* bell-ſhaped, ſmooth, red. *Petals* white, obovate, one-third the length of the limb. *Germen* ſmooth.

26. R. *ferox*. Strong-thorned Californian Gooſeberry.—Prickles ſcattered, ſetaceous, very ſlender; thoſe under the buds three together, combined, awl-ſhaped. Leaves five-lobed, rugoſe, downy beneath. Stalks ſingle-flowered. Segments of the calyx lanceolate, twice the length of its tube. Germen and fruit prickly.—Gathered by Mr. Menzies, near Port Trinidad, in California. A very fine remarkable ſpecies, whoſe *branches* are thickly covered with tawny, ſetaceous, prominent prickles, about a quarter of an inch in length, and armed under each bud, with three very ſtrong and pungent awl-ſhaped ones, an inch long, having ſometimes leſſer reflexed prickles at their baſe. The *leaves* are not unlike our common Gooſeberries, but more rugoſe; and denſely downy at the back. *Flower-ſtalks* ſolitary, ſimple, longer than the leaves. *Bracteas* ſcattered. *Flowers* drooping, large and handſome. *Calyx* three quarters of an inch long, funnel-ſhaped, downy and briſtly; as far as we can judge from the dried ſpecimens it ſeems of a fine crimſon; its ſegments lanceolate, ribbed, erect, full twice as long as the tube. *Petals* half the length of theſe ſegments, erect, pale, obtuſe. *Stamens* the length of the calyx. *Anthers* large, oblong-heart-ſhaped, pointed. *Germen* covered with prominent, glandular briſtles, which harden, as the *fruit* advances, into ſtiff, ſharp ſpines, ſo that whatever its flavour may be, it ſeems perfectly inacceſſible, in the common way of eating gooſeberries.

27. R. *rotundifolium*. Round-leaved Carolina Gooſeberry. Michaux Boreal-Amer. v. 1. 110. Purſh n. 11.—"Prickles ſolitary under the buds. Leaves nearly orbicular, ſlightly downy; lobes roundiſh, obtuſe. Stalks ſingle-flowered. Limb of the calyx tubular. Fruit ſmooth." Native of the high mountains of Carolina. *Michaux*.

28. R. *hirtellum*. Small-leaved Canada Gooſeberry. Michaux Boreal-Amer. v. 1. 111. Purſh n. 12.—Prickles ſolitary under the buds, ſmall. Branches ſomewhat hiſpid. Leaves three-cleft half way down, ſlightly notched. Stalks ſingle-flowered. Fruit ſmooth.—Found among rocks, on the Allegany mountains; from Canada to Virginia, flowering in May and June. *Purſh*. *Leaves* ſmall. *Berries* red.

29. R. *gracile*. Slender-ſtalked Blue Gooſeberry. Michaux Boreal-Amer. v. 1. 111. Purſh n. 13.—Prickles ſolitary under the buds, very ſhort. Leaves acutely lobed and cut, downy on both ſides. Footſtalks ſlender. Flower-ſtalks capillary, erect, moſtly two-flowered. Calyx bell-ſhaped. Fruit ſmooth.—On rocks, and in mountain meadows, from New York to Carolina, flowering from April to June. *Calyx* ſmooth. *Berries* purple or blue, of an excellent taſte. *Purſh*.

30. R. *ſtamineum*. Scarlet-flowered Californian Gooſeberry.—Branches finely hiſpid. Prickles ſeveral under each bud, unequal. Leaves rounded, ſlightly three-lobed, ſmooth. Stalks two-flowered. Calyx hemiſpherical; limb in very long parallel ſegments. Petals equal to the limb. Stamens thrice as long.—Gathered by Mr. Menzies in California. *Branches* brown, clothed with copious, extremely fine, prominent, capillary briſtles. *Prickle* under each bud rigid and ſharp, about one-third of an inch long, with ſeveral ſmaller deflexed ones at the baſe. *Leaves* not an inch long, quite ſmooth, veiny; paler beneath; orbicular and entire, except three very ſlight, ſcarcely notched, obtuſe lobes, at the extremity. *Footſtalks* ſhort, ſmooth. *Flower-ſtalks* longer than the leaves, hiſpid, glandular, two-flowered, with a ſingle roundiſh *bractea*. *Flowers* ſcarlet. *Calyx* with a very ſhort hemiſpherical tube, hiſpid like the *germen*; its limb five times as long, in five oblong, parallel, ſmooth ſegments. *Petals* of the ſame length, but rather paler and more obtuſe. *Stamens* capillary, ſtraight, parallel, projecting (four of them at leaſt) with the *ſtyle*, full an inch out of the flower; the fifth is perhaps abortive. We know nothing of the *fruit* of this beautiful ſpecies, whoſe *flowers* have the aſpect of a *Fuchſia*.

31. R. *triflorum*. Three-flowered Mountain Gooſeberry Willd. Hort. Berol. v. 1. 61. t. 61. Purſh n. 14.—Prickles ſolitary under each bud. Leaves ſmooth, three or five-lobed, notched. Stalks about three-flowered. Petals ſpatulate, undulated. Style prominent, hairy, divided.

Fruit

Fruit smooth.—On the Blue mountains; from Pennsylvania to Virginia, flowering in May and June. *Pursh.* The *partial flower-stalks* are very long. *Bracteas* very short. *Flowers* yellowish-green, with white *petals*. *Berries* pale red, small.

32. R. *oxyacanthoides.* Hawthorn-leaved Gooseberry. Linn. Sp. Pl. 291. Willd. n. 15. Ait. n. 13. Pursh n. 15. (Grossularia oxyacanthæ foliis amplioribus, e sinu Hudsonio; Dill. Elth. 166. t. 139.)—Branches clothed with bristly prickles; those under the buds larger, mostly solitary. Leaves smooth, three-lobed, notched. Stalks one or two-flowered, shorter than the footstalks. Fruit smooth.—Native of rocky places at Hudson's-Bay, Canada, New York, &c. flowering in April and May. It is said to have been cultivated in England in 1705, and was certainly in the Eltham garden near thirty years after. This resembles the common gooseberry in habit, but the *branches* are covered with innumerable, fine, bristly, not very rigid prickles, besides the larger ones, proper to this section of the genus, which are mostly solitary under each bud. *Leaves* larger, more deeply cut than in our gooseberries, smooth. *Flowers* drooping, one or two on each stalk. *Fruit* globose, the size of a black currant, purple, or almost black, with a cærulean bloom on the surface; slightly acid.

33. R. *lacustris.* Swamp Cluster Gooseberry. "Pers. Syn. v. 1. 252." Pursh n. 16. (R. oxyacanthoides; Michaux Boreal-Amer. v. 1. 111.)—Branches clothed with bristly prickles; those under the buds numerous, aggregate, pungent.—Leaves deeply lobed, doubly notched. Clusters downy, drooping, many-flowered. Fruit hispid.—Found in swamps, on the mountains, from Canada to Virginia, flowering from April to June. *Pursh.* Many persons have confounded this with the last, and we are not sure that the two are distinguished by our leading gardeners. We received specimens of the present from the Edinburgh garden, so long ago as 1782, with the name of *R. oxyacanthoides.* Another, in the herbarium of the younger Linnæus, is marked *armatum*; an excellent name, given, we believe, by sir J. Banks or Dr. Solander, who could not overlook the characters which so clearly distinguish this from the true *oxyacanthoides.* These are not only the deeply divided vine-like *leaves*, but the numerous, combined, ascending *prickles*, almost palmate at their base, which stand under each leaf or bud; and also the long hairy glandular clusters of *flowers*, with a prickly *germen* and *fruit.* The *branches* are beset with abundance of rigid prickly bristles, rather stronger than those of *oxyacanthoides.* The *flowers* are of a dull, tawny, yellowish-green. "*Berries* amber-coloured, or brown." *Pursh.*

34. R. *cynosbati.* Thorny-fruited Cluster Gooseberry. Linn. Sp. Pl. 292. Willd. n. 16. Ait. n. 14. Pursh n. 17. Jacq. Hort. Vind. v. 2. t. 123.—Branches smooth. Prickles one or two under each bud, simple. Leaves five-lobed, downy beneath. Clusters drooping, of few flowers. Fruit armed with strong thorns.—On the sides of hills and rocks, in the Allegany mountains, and in Canada, flowering from April to June. *Flowers* green. *Berries* dark brown, and covered with thorns. *Pursh.* Miller cultivated this species at Chelsea, where we believe it still remains. The *leaves* are downy on both sides, but especially beneath. *Prickles* mostly solitary, variable in size; those on the large globular fruit are peculiarly strong.

We have thus more than doubled Willdenow's catalogue of species, in this genus. Some of the newly discovered ones, from North America, are likely to prove great acquisitions to our kitchen gardens, provided they bear fruit in this climate; of which, till the experiment is fairly made, there must always be some uncertainty.

Ribes, in *Gardening*, contains plants of the hardy, deciduous, shrubby kind, of which the species cultivated are; the common currant (R. rubrum); the common black currant (R. nigrum); the rough-fruited gooseberry (R. grossularia); the smooth-fruited gooseberry (R. uva crispa); the procumbent gooseberry (R. reclinatum); the hawthorn-leaved currant (R. oxyacanthoides); and the prickly-fruited currant (R. cynosbati).

It is observed by Martyn, that the first sort is very apt to be infested with the aphis ribes, in which case the green leaves become red, pitted, and puckered. It has been long cultivated in the garden, and greatly improved. There are several varieties; as the common sort, with small red fruit; with white fruit; with pale fruit, commonly called the Champaign currant, differing only in being a pale red or flesh-colour. But since the white and red Dutch currants have been introduced and become common, the old sorts have been almost banished, and are now rarely to be found. And Mr. Forsyth mentions the fine new white Dutch, long-branched red, striped-leaved red-white currant, and large pale and red Dutch.

There are also the sweet currant, the small-fruited currant, and a variety with blotched leaves, which is kept in some plantations; but as the variegation is apt to go off when the plant is vigorous, it scarcely deserves a place in them.

Of the second there is a sort often termed the American black currant. The berries have a very peculiar flavour, which many persons dislike; but are commonly eaten in puddings in some parts, and make a tart little inferior to the cranberry. The juice of which is also frequently boiled down to an extract, with the addition of a small proportion of sugar; in this state it is called rob, and used in sore throats and other diseases.

Currants in general are by some supposed the most useful of all the small fruits, as serving either for table or culinary uses, as well as for wine, and continuing long in succession with due management. The black sort is seldom sent to table as a fruit for that purpose. But it is a sort which may be infused in spirit of any kind, in which way they make a good liquor.

The third, or rough-fruited, sort is a low branching shrub, which has the berries pendulous and hairy. And it is observed by the editor of Miller's Dictionary, that if the bracteas do not distinguish this from the following, the roughness or smoothness of the berries will hardly do it, as Mr. Robson has found that seeds from the same plant will produce both rough and smooth fruit. He cannot regard them as different species.

The fourth, or smooth-fruited, sort has the berry pulpy, subdiaphanous, pale, amber-coloured, red or purple, smooth, and the pulp watery and sweet. And Martyn remarks, that the gooseberry seems to have been formerly a fruit in very little esteem, but has received so much improvement, that it is now become valuable, not only for tarts, pies, and sauces, both fresh and preserved in bottles, but as an early desert fruit, and preserved in sugar for winter use to answer the same purpose.

It may be noticed, that the most important varieties of the red kind are, the hairy, smooth, deep red, damson or dark red, blueish, red raspberry, early black-red, Champaigne, &c. Of the green kind; the hairy, smooth, Gascoigne, raspberry, &c. Of the yellow kind; the great oval, great amber, hairy amber, early amber, large tawny or great mogul, &c. And of the white kind; the common, white-veined, and large crystal. But besides these, there is the rumbullion, large ironmonger, smooth ironmonger, hairy globe, and innumerable

innumerable others, fome of very large fize, annually raifed from feed, weighing from ten to fifteen pennyweights; however, there are fmall ones better tafted. There are faid to be upwards of two hundred, at leaft in name.

And Mr. Forfyth has given the following lift from the catalogue of Meffrs. Kirk, nurferymen, at Brompton, near London.

The fupreme red, perfection red, high fheriff of Lancafhire, royal George, unicorn, rough amber, white walnut, Ackerley's double bearer, royal oak, Mifs Bold's, fparkler, Ackerley's Rodney, Hampfon's Cæfar, Monk's Charles Fox, St. John, pigeon egg, Worthinglowe's conqueror, golden eagle, Royder's triumph, Williamfon's yellow hornet, Swingham, Jackfon's golden orange, Goliah champion, hairy amber, Nixon's golden eagle, Worthington's white lily, Laylord's feedling, Nixon's white heart, Riding's old England, Bakeley's Swingham, Tillotfon's St. John.

The fame writer alfo adds another lift of the largeft new forts which were fhewn in Lancafhire, in the fummer of 1800, with their colour and weight, as communicated by Meffrs. M'Niven, nurferymen, Manchefter.

It is obferved, that in favourable feafons, many of the above forts have been known to weigh more by feveral pennyweights.

In all the fouth-eaftern parts of Lancafhire there are a great number of little focieties held by the labouring and manufacturing workmen, and the gardeners; where thefe forts of fruits are annually exhibited, under many different arbitrary names and defignations, as *Goliahs, golden drops*, &c. and their merits and capabilities of improvement finally fettled and decided upon.

The fifth fort has the fruit when ripe commonly dark purple, but fometimes red or even yellow.

In the fixth kind the fruit is fmall and round, the fize and fhape of a currant; the colour at firft purple, but when ripe, dark purple with a blue bloom; it is fmooth, on a fhort flender ftalk.

Method of Culture in the Currant Kind.—In general thefe may be raifed with great facility from layers, feed, cuttings, and in other ways. In the firft of thefe modes, when the trees are cut low, Mr. Forfyth advifes the laying down fome of the branches either in the winter or fpring feafons, when the ground in the quarters or rows is dug, which fhould always be done annually. In the autumn following, thefe layers will have made fine roots; then they may be taken off, and planted out where they are to ftand, and they will moftly bear fine fruit in the following fummer.

But in the fecond method, the cuttings fhould be chofen of the ftrongeft and ftraighteft fhoots, which fhould be cut fix or eight inches in length, and be planted out on an eaft or north border, in the early autumn, at the diftance of a foot from row to row, leaving only a few inches out of the ground. In this way they may be kept perfectly free from weeds. In dry weather, during the fpring, they fhould be often refrefhed with water. Some alfo raife thefe plants from fuckers; but this is a method that fhould be avoided as much as poffible, as they never grow handfome, and are apt to throw out fuckers afterwards.

With refpect to the feed, it fhould be fown on a border where the mould is fine, either in the autumn or early in the fpring; and the young plants, when they appear, be kept free from weeds. When they have attained fufficient growth, they may either be planted out where they are to remain, or be fet out in nurfery-rows. However, Mr. Forfyth obferves, that under the bufhes that have been covered for late fruit, plenty of felf-fown plants may conftantly be found, which he advifes to be planted out by themfelves. And thofe who make currant-wine may, he thinks, fave the feed, after the fruit is fqueezed, and dry it: it may then be fown in the manner directed above, by which, moft probably, fome fine varieties may be obtained. As in many gardens there ftill remains, the fame writer remarks, a fmall fort of red and white currant not worth cultivating, he would advife thofe who have any of them to root them up, and plant in their room the large red and white Dutch, the long-bunched red, and Champaigne large pale red. Thefe kinds of plants may be planted out, it is fuggefted, either in the quarters, or fingle rows round the edges of the quarters, in the gardens or other places. And he would particularly

particularly recommend planting a few against a south or west wall, or paling, which will produce fruit much earlier than in the quarters, &c.: also to plant some between other fruit-trees, on north walls, or palings, for later crops. These may be covered with double nets, to preserve them from birds; tucking in a few fern branches between the two nets, which will prevent the heat of the sun and drying winds from shrivelling the fruit. In the quarters they should be covered with mats, for the same purpose; at the same time permitting all the leaves to remain on the bushes, to shade the fruit, and make it keep the longer in a proper state.

In what respects the pruning of the bushes, the work may, according to the above author, be begun in the month of November, and continued till March, as it suits the planter's convenience. And they should never be left too thick of wood; but a great deal depends on the management of them in summer, to have strong and fine wood for the following season. If they have been neglected for some years, and suffered to run up to long naked wood, they must, in his opinion, be cut down near the ground: they will then send forth fine strong shoots. In this case, he would recommend heading down every other tree, and cutting the others partially, by taking out every other branch as near as can be to the ground, unless they are trained up with single stems; in which case, it will be necessary to cut them as near as possible to where the branches begin to break out and form the head. And in the winter pruning, the strongest and finest shoots should be preserved, leaving them from nine to eighteen inches long, according to their strength, and from eight to ten inches apart, and as regular as possible from top to bottom of the tree; taking care to cut out all the dead and weak shoots. And particular attention should be paid in summer, keeping the middle of the bush open to admit the sun and air; preserving the finest and strongest shoots that are nearest the stem. Some, he remarks, are fond of training them up with single stems, to a considerable height, to form fine round heads, which are very ornamental, if not suffered to run up too high; as, in that case, they are liable to be broken by the wind, if not well supported by stakes. Care must be taken not to let the shoots run to more than six inches long, because such short shoots will not be so liable to be damaged by the wind as long and weak ones are, especially when loaded with fruit. He prefers dwarfs from three to four feet high.

Further it is added, that the same manner of pruning, &c. will do for black currants; but as they grow stronger than the red or white, the shoots should be left thinner, and laid in longer, which will make them produce larger and finer fruit. And those against walls and palings should have the shoots laid in thinner than those in the quarters, and trained as horizontally as possible; shortening them, in the winter pruning, to a foot or eighteen inches, according to the strength of the shoots.

As this sort of fruit is very liable to be devoured by earwigs, which take shelter under their leaves and branches, bundles of bean-stalks should, he suggests, be hung up some time before the bushes are covered with mats or nets. If proper attention be not paid to this, the fruit will generally suffer very much from these insects. After the bushes are covered, take the mats off once in three or four days, and kill the earwigs that have got in the bean-stalks, which it will be necessary still to keep hung up. As there is a sweetness in the inside of bean-stalks, which attracts the earwigs, they very readily take shelter in them from rain. By proper attention to these directions, these destructive insects may be kept under, and the greater part of the fruit be preserved. It is also necessary to carefully stock up all suckers at the roots of the trees, and keep them as clean as possible; otherwise they will prevent the sun and air from penetrating to the roots, and greatly weaken and injure the trees.

These plants are very liable to be infested with aphides, and other insects, from which they should be freed as soon as possible, by proper picking, washing, and liming.

Culture in the Gooseberry Kind.—All these are capable of being raised by cuttings and layers, as well as seeds for new varieties. They are likewise sometimes increased by suckers; but this last is not an adviseable method, as the plants raised in this way are more apt to throw out suckers than those from cuttings or seed. The cuttings should be made from the strongest and cleanest shoots, and have the length of seven or eight inches, being planted out in the early autumn, in a border which has an eastern or northern aspect, at the distance of about a foot from row to row, and having only about three or four inches of each cutting above the ground; as by this means they may be kept clean by hoeing. They require to be frequently watered in the spring season, when the weather is dry.

Also the layers may be laid down any time in the autumn or spring season, in the common way, when they readily strike root; and in the following autumn, may be taken off, and planted out where they are to remain, or in nursery-rows, to get strength to be finally planted out.

And the seed obtained from the ripened berries should be sown in the autumn, or very early spring, in a bed of fine light mould. The plants come up readily, and should be kept perfectly clear from weeds; and when they have had one or two years' growth, may be removed into nursery-rows, in the same manner as the currants, to remain till they become fit for being planted out. In this way good new varieties may be procured. Mr. Forsyth remarks, that the gardeners in the vicinity of Manchester have made great additions to the varieties of this fruit; and by mixing up a rich soil to plant them in, carefully watering, shading, and thinning the fruit, have brought the berries to a size much larger than had been before met with in this country; but that those of some of the layers are much thicker in the skin, and not so well flavoured as many of the old sorts.

In most parts of Lancashire, this is indeed a kind of fruit which is uncommonly fine, and of a very large size, in both the red and white kinds; and in many of the southern and south-eastern parts, very great attention, in numerous instances, is bestowed in the cultivation and improvement of it, so as to render it of an unusual magnitude and fine appearance. This is chiefly effected by much more pruning and thinning than that which is generally had recourse to with these sorts of plants, frequent digging about them, and a very liberal use of well rotted stable dung incorporated with the mould which is applied near their roots.

As to the methods of planting out this sort of plants, they are extremely various. According to Mr. Forsyth, the market gardeners in the vicinity of the metropolis set them out in rows from eight to ten feet apart, and six from plant to plant. In cases of this sort, he recommends that they should be pruned in the autumn, as about the beginning of October, when the ground between them may be planted with coleworts, or beans for a spring crop; and by so doing, there will be no occasion to tread over the ground, and hurt the coleworts, in pruning the bushes; as, before the gooseberries begin to shoot, the coleworts will be all cleared off the ground. And after this time, (or before, if you find it convenient,) a good coat of rotten dung should be laid on the ground; then dig it, and plant early potatoes, but not so near as to hurt the gooseberries by their growth. He likewise advises that the roots of gooseberries should be kept clear to admit the sun and air. In small gardens, he would recommend planting them in a quarter by themselves, at the distance of six feet between the rows, and four feet from plant to plant: they may be planted round the edges of the quarters, about three feet from the path; in which case, the ground will be clear for cropping, and a man, by setting one foot on the border, can gather the gooseberries, without injuring the crop that may be on the border. Also that, as they like a rich soil, they should be dunged every year, or at least have a good coat of dung once in two years. They should never be planted under the shade of other trees, as it injures the flavour of the fruit.

And in respect to the pruning of the bushes, it is a practice too common, Mr. Forsyth thinks, to let them branch out with great naked stems, suffering them to remain in that state for years. When that is the case, they should be cut down near to the ground in the winter pruning, as it will make them throw out fine strong healthy shoots, which will bear fruit the second year; and as gooseberry bushes, in general, bear their fruit on the second year's wood, great care should be taken in summer to keep the middle of the bush clear, to admit a free air, leaving the finest and strongest shoots from six to ten inches distant from each other. This will, he conceives, help to ripen and harden the wood. It is a practice with some to shorten the shoots in the autumn or winter pruning, which should be always near to a wood-bud; which may be known by its being single, whereas fruit-buds are in clusters. The shoots may, he thinks, be shortened to eight or ten inches, according to their strength. Some leave them at full length for three or four years, thinning out those that are superfluous. He advises always to leave a proper number to be trained up between the full length shoots, to succeed them when they are tired of bearing; and then to cut the old ones down to the young ones that are to succeed them. By these means, the bushes may always be kept in a constant state of bearing. Those branches which were cut the first year will, in the second, throw out short dugs, or spurs, which produce the fruit; and these should by no means be cut off, unless the branches are in a sickly state, and require to be cut close down, when the bushes are overloaded with fruit. It will then, in his opinion, be necessary to cut out a good deal of the old wood, to assist nature to recover herself, after producing so great a quantity of fruit.

He likewise advises that great attention be paid to the cultivation of the early and late sorts. In some old gardens, in particular, there are, he observes, very valuable sorts that have been of late too much neglected; he would therefore recommend to those who live in the neighbourhood of such gardens, to observe their time of ripening, and to cultivate those especially which are early and late. And he adds, that it is a practice with some to clip the tops of gooseberries with a pair of garden shears, as they would clip a thorn hedge; this he by no means approves of, as the fruit will not be half the size, nor of so fine a flavour, as when the bushes are kept clear of such wood as is unnecessary.

Farther it is recommended that great care should be taken in spring and summer to stock, or grub up, all the suckers from the roots of the bushes, leaving their stems clear and unencumbered. And as many of the Lancashire sorts are apt to grow horizontally, and the branches frequently trail on the ground, which renders them liable to be broken by high winds, especially when they are loaded with fruit, he would recommend two or three hoops to be put round them, to which the branches may be tied, to support them, and prevent their being broken by the wind, or any other means.

In cases where it is wished to have them late, they should be planted on north walls and palings, between the other trees, when they may be removed as the trees begin to meet. If laid in thin, they will bear very fine and handsome fruit. He would advise to plant the finest late sort; as by this method the table will be supplied much longer than by the common custom of planting in quarters of the garden.

Also immediately after pruning, he always applies the plaster composition to the ends of the shoots and cuttings; and he finds it of great use in preventing the exhalation of the sap, and preserving the cuttings till they take root, and become established.

It may be observed that these sorts of plants are very much infested with a small green caterpillar, which frequently devour both leaves and fruit: great attention is of course necessary to observe their first appearance on the bushes; as, if not destroyed early, they increase so fast, that they soon devour all the leaves, and the fruit is good for nothing. It is noticed, that they first appear generally on the edges and under-sides of the leaves. In order to destroy them, he advises to take some sifted quick-lime and lay it under the bushes; but not at first to let any of it touch the branches or leaves; then shake each bush suddenly and smartly, and the caterpillars will fall into the lime; if the bush be not shaken suddenly, the caterpillars, on being a little disturbed, will take so firm a hold as not easily to be shaken off. After this is done, some of the lime should be sifted over the bushes; this will drive down those which have lodged on the branches. The caterpillars ought, in his opinion, to be swept up next day, and the bushes well washed with clear lime-water mixed with urine; this will destroy any caterpillars that may still remain, and also the aphides, if there are any on the bushes at the time.

Forcing.—It may be stated, that sometimes trees of the gooseberry and currant kinds are forced for early fruiting, by means of artificial heat in fruit-forcing-houses, hot-walls, or forcing-frames, &c. For this purpose, some young trees should be planted in largish pots, one plant in each, and being advanced to a full state of growth for plentiful bearing, should be introduced in any of the above forcing departments that are in work by fire, or hot-bed heat, or both, in forwarding any principal sorts of fruit-trees, plants, or flowers, at the proper season, as about January or February, in which the same culture, in regard to the degree of heat, and other requisites, necessary for the other trees, &c. is suitable for these. Water should be given occasionally to the earth in the pots, and sometimes after the fruit is set, throwing it lightly over the branches on a warm sunny day; and they will thus produce ripe fruit in April or the following month.

However, the forcing of this sort of fruit is now seldom much attended to, in consequence of other finer sorts being so common.

Ribes, in the *Materia Medica.* The *ribes rubrum* or *rutilum, i. e.* the red currant, and the *ribes album*, or white currant, are varieties of the same species, and therefore the fruit of both, considered in both a botanical and medical sense, is perfectly analogous. The red currant is abundantly cultivated in our gardens, from which we are supplied with the fruit; and this, on account of its grateful acidity, is universally acceptable, both in its natural state, and as variously prepared by art with the addition of sugar. The juice is a most agreeable acid in punch. If equal weights of picked currants and pure sugar are put over the fire, the liquor

liquor that separates spontaneously is a most agreeable jelly. The juice of red currants, with sugar, is a common beverage at Paris, where it is generally preferred to orgeat or lemonade. Dr. Cullen classes this fruit with the alimentary plants, and being generally and exclusively considered as such, it was not received in the British catalogues of the Materia Medica till that published in a late collection of the London Pharmacopeia: but it is omitted in the last edition. The medicinal qualities of red currants appear to be similar to those of the other subacrid fruits, which are esteemed to be moderately refrigerant, antiseptic, attenuant, and aperient. Hoffman and Boerhaave had great confidence in the efficacy of these fruits in obstinate visceral obstructions. They may be used with considerable advantage to allay thirst in most febrile complaints; to lessen an increased secretion of bile; and to correct a putrid and scorbutic state of the fluids, especially in sanguine temperaments; but in constitutions of a contrary kind they are apt to occasion flatulency and indigestion,

The *ribes nigrum*, or black currant, has berries larger than those of the red; and besides possessing the properties in common with the "fructus acido-dulces," they are also said to be peculiarly useful in sore throats; and to manifest a diuretic power in a very considerable degree. In cases of inflammatory angina, they may be advantageously employed to answer the same intentions as gargles, and from their efficacy in this respect they have acquired the name of "Squinancy berries," but the proofs of their diuretic powers seem to want confirmation. With respect to their former application and utility we may observe, that the black currant jelly in common domestic use is rendered less efficacious by having too much sugar in its preparation. The fruit both of this, and of the red currant, afford a pleasant wine; and that made of the former is mentioned by Haller, "ex eo optimum vinum fieri non deterius vinis verioribus viteis, quando annuum est." The leaves of the black currant are extremely fragrant, and have been recommended for their medicinal virtue, which Bergius states to be "mundificans, pellens, diuretica." An infusion of these leaves is said to have the taste of green tea, and when prepared from the young leaves, is to some people very agreeable. The official preparations of the black currant berries in the late London Pharmacopeia (but omitted in the last edition) were the "Syrupus ribis nigri," and the "Succus ribis nigri inspissatus." Woodv. Med. Bot. See CURRANTS.

RIBIERS, in *Geography*, a town of France, in the department of the Higher Alps, and chief place of a canton, in the district of Gap; four miles N.W. of Sisteron. The place contains 1301, and the canton 3939 inhabitants, on a territory of 180 kiliometres, in nine communes.

RIBNA, a town of Russia, in the government of Kolivan, on a river of the same name; 112 miles S.E. of Krasnoiarsk.

RIBNIK, a town of Silesia, in the principality of Ratibor; 13 miles E. of Ratibor. N. lat. 50° 3′. E. long. 18° 30′.—Also, a town of European Turkey, in Walachia, on the Alaut; 44 miles S. of Hermanstadt. N. lat. 45° 19′. E. long. 24° 8′.—Also, a town of European Turkey, in Walachia, on the Ribnik, otherwise Rymnick, as it is called by the Russians; the see of a Greek bishop. From a severe battle fought here in 1789, between the Austrians and Russians against the Turks, Suwarrow, who commanded the Russians, and defeated them, was created by the emperor Leopold, a count of the empire, invested with the order of St. Andrew, and honoured with the title of Rymniski by the empress Catharine; 100 miles S. of Jassi. N. lat. 45° 36′. E. long. 27° 4′.—Also, a river of Walachia, which runs into the Siret, near Dubravitza, on the borders of Moldavia.

RIBNITZ, a town of the duchy of Mecklenburg, situated on a large lake, near the mouth of the Reckenitz; 12 miles N.N.E. of Rostock. N. lat. 54° 17′. E. long. 12° 35′.

RIBNITZY, a town of Poland, in the palatinate of Braclaw; 64 miles S. of Braclaw.

RIBNO, a town of Prussia, in the province of Oberland; 15 miles N.N.E. of Ortelsburg.

RIBNOI, a town of Russia, in the government of Jaroslavl; 40 miles W.N.W of Jaroslavl. N. lat. 57° 45′. E. long. 39° 14′.

RIBS, in *Anatomy*, the bones forming the sides of the chest, attached to the spine behind, and terminating in front in portions of cartilage, some of which are fixed to the sternum, the others not. The former are called *true*, the latter *false* ribs. They are described in the article LUNG of this Cyclopædia.

RIBS, *Fractures of the*, in *Surgery*. See FRACTURE.

RIBS *of Fish*. There is a very great variety in the shape and other peculiarities of the ribs of fish. They are in some smooth, and flattened sideways, as in the cyprini; in others they are rounded, as in the cotti and gadi. In the cyprini the several species have from thirteen to nineteen ribs on a side, and the vertebræ are from thirty-seven to forty-nine in number, differing greatly in number in the several species of the same genus. The ribs in many fish adhere to the vertebræ, by means of cartilages, and seem only continued parts of them; but in others they are free and loose, and do not so much as touch the vertebræ. We find instances of the first sort of structure in the cyprini, salmons, &c. and of the other in the perch, the gadi, and the pleuronectæ. In the spinose fishes, the last vertebra always is terminated by a pair of broad apophyses placed perpendicularly, and touching one another, and by means of cartilages these are fixed to the bones of the tail. Artedi Ichthyolog. See *Anatomy of* FISH.

RIBS, a figurative expression for the timbers or frames of a ship, arising from the comparison of it with the human body, as the keel with its keelson, to the back-bone, and the timbers to the ribs; for the former unite and support the whole fabric, since the stem and stern-frame, which are raised on the ends of the keel, may be said to be a continuation of it, and serve to connect and inclose the extremities by the hawse-pieces forward, and the transoms abaft, as the keel forms and unites the bottom by the floor-timbers. The idea, if carried further, may in a manner represent the muscular parts of the human fabric; for the wales, clamps, and thickstuff, at the different heads of the timbers, are as so many muscles or strong ligaments to connect the ribs together, while the planking of the bottom and top-sides, which is thinner, may be compared to the skin or covering of the whole; and hence planking is often termed, *skimming* the ship.

RIBS *of a Parrel*, short flat pieces of wood hollowed on the back, having a hole near each end, through which the parrel rope is reeved. See PARREL.

RIBS, among *Jewellers*, the lines or ridges which distinguish the several parts of the work, both of brilliants and roses.

RIB-WORT, in *Botany*. See PLANTAIN.

RICA, among the Romans, a veil with which the ladies covered their heads.

RICÆ, ῥικαι, surgical bandages for the head.

RICARD, DOMINIC, in *Biography*, was born at Toulouse in 1741, and entered into the congregation of the Christian

Chriſtian doctrine, and became a diſtinguiſhed profeſſor in it. He quitted the ſociety after ſome years, and took up his reſidence at Paris, where he employed himſelf in inſtructing youth, and in literary purſuits. He was celebrated for his deep knowledge in the Greek language, and engaged in the great taſk of tranſlating the whole works of Plutarch. Between the years 1783 and 1795 he publiſhed his verſion of that philoſopher's moral works, in 17 vols. 12mo.: of the Lives he only publiſhed 4 vols. 12mo. He publiſhed likewiſe a poem, entitled "La Sphere," in eight cantos, 8vo. 1796, which contains a ſyſtem of aſtronomy and geography, enriched with notes, and notices of Greek, Latin, and French poems, treating on aſtronomical ſubjects. Ricard died in 1803. He was diſtinguiſhed by modeſt merit, and the practice of all the ſocial virtues.

RICAUT, *Sir* Paul, was the youngeſt ſon of ſir Peter Ricaut, knight, ſuppoſed to be a merchant in London. The time and place of the birth and education of the ſubject of this article are not known, but he appears to have travelled during ſeveral years in Europe, Aſia, and Africa. In the year 1661 he went out as ſecretary to the earl of Winchelſea, the ambaſſador extraordinary to the Ottoman Porte. Here he remained eight years in that poſt. In 1663 he publiſhed the treaty or capitulation concluded between Charles II. and the Turkiſh ſultan, in which was the favourable article, that Engliſh ſhips ſhould be exempted from ſearch for foreign goods. When his connection with the Porte was expired, he was appointed Engliſh conſul at Smyrna, an office which he held about eleven years, to the entire ſatisfaction of the Turkey company, and with the reſpect and attachment of all the Europeans in that city. Upon his return, he employed himſelf in literary occupations till the year 1685, when he accompanied the earl of Clarendon, lord-lieutenant of Ireland, as his ſecretary for Leinſter and Connaught. He was nominated by James II. one of his privy-council for Ireland, and judge of the admiralty court, and received the honour of knighthood. After the revolution, he was ſent by king William as his reſident to the Hanſe towns, in which poſt he continued ten years. He died in England, in the year 1700, literally worn out with age and long ſervices. Independently of his high character as a diplomatiſt, he was celebrated for his knowledge of the learned languages, and alſo of the modern Greek, the Turkiſh, the Italian, Spaniſh, and French. As an author, he is known by "The preſent State of the Ottoman Empire;" "The preſent State of the Greek and Armenian Churches;" "A Continuation of Knolles' Hiſtory of the Turks." He continued "Platina's Lives of the Popes" to his own time. He tranſlated from the Spaniſh, "The Royal Commentaries of Peru, by Garcilaſſo de la Vega." A paper of this author is inſerted in the Tranſactions of the Royal Society, of which ſociety he was a member. Biog. Brit.

RICCATI, Vincent, a learned Italian Jeſuit, was born at Caſtel-Franco, in the territory of Treviſo, about the year 1707. His genius inclining him chiefly to the ſtudy of the mathematical ſciences, he cultivated them with ſo much ſucceſs, that his ſuperiors ſelected him as a proper perſon to teach them to others. He accordingly was choſen profeſſor in the college at Bologna, which he filled with reputation till the ſuppreſſion of the order in 1773. He died in 1775, leaving behind him ſeveral works that teſtify his high merit as a ſcholar, among which is "A Treatiſe on the Integral Calculus," in 3 vols. 4to. He did not confine himſelf to the abſtract mathematics, but paid much attention to the ſtudy of hydraulics; a branch of ſcience of the utmoſt importance in all the northern Italian ſtates, where the many and rapid rivers expoſe the country to continual inundations. In this line he appears to have rendered conſiderable ſervice to the Venetian territories; ſo much ſo, that in 1774 a gold medal was ſtruck in his honour.

RICCI, Bartholemew, a learned Italian, was born at Lugo, in Romagna, in the year 1490. He ſtudied under Amaſeo in Bologna, and for further improvement viſited Padua and Venice. He paſſed ſome years in the houſe of Giovanni Cornaro, as preceptor to his ſon, who was afterwards a cardinal; and for ſome time kept a ſchool at Ravenna. Through the recommendation of Calcaquini, he was invited, in 1539, to the court of duke Hercules II. of Ferrara, to undertake the education of the princes Alfonſo and Luigi. He there acquired the affection of his pupils, and the eſteem of the learned. He died at the age of 79, in the year 1569. The principal works of Ricci are "Orations," and "Epiſtles," the Latin ſtyle of which has been much applauded, as a happy imitation of that of Cicero. The moſt laborious of his works is entitled "Apparatus Latinæ Locutionis," being a Latin lexicon, in two parts; the firſt containing the verbs, and the ſecond the nouns with which they are joined. It was printed at Venice in 1535. Ricci alſo wrote a comedy in Italian proſe, entitled "Le Balie," which is well ſpoken of; and ſome Italian poems, which have appeared in collections.

Ricci, Matthew, an eminent miſſionary, was born of a good family at Macerata, in 1552. He was ſent to ſtudy the law at Rome, where, at the age of 19, he entered into the ſociety of Jeſuits. He had not completed his theological ſtudies, when he followed to the Eaſt Indies his preceptor, father Valignan. During his abode at Goa, he applied aſſiduouſly to the language of China, to which country he was deſtined. In 1583 he arrived at Caoquin, in the province of Canton, where he ſettled with ſome brethren. To ingratiate himſelf with the Chineſe, he made a map of the world, in which, whilſt he corrected their prejudices with reſpect to the relative dimenſions of their country, he complied with them by altering the meridian, ſo as to place it in the centre. It was not till 1600 that he was able to gain acceſs to the emperor at Peking, employing the pretext of bringing him a preſent of curioſities from Europe. He was well received, and permitted to ſettle in that capital, where his mathematical ſkill rendered him acceptable to the court and men of letters. He purchaſed a houſe there, and built a church; and the progreſs, ſuch as it was, which Chriſtianity made in the metropolis of China, was greatly owing to his exertions. He died there in 1610, leaving curious memoirs on China, of which father Trigault made uſe in his work "De Chriſtiana Expeditione apud Sinas."

Ricci, Michael-Angelo, an Italian cardinal, and able mathematician, in the 17th century, was deſcended from a noble family originally from Bergamo, and born at Rome in the year 1619. In the courſe of his ſtudies, he conceived a powerful inclination for the mathematics, which was confirmed by Torricelli, during the temporary reſidence of that philoſopher at Rome. Under his directions, Ricci's genius was carefully cultivated, and his progreſs reflected great honour both on the tutor and pupil. After Torricelli left Rome, he maintained a regular correſpondence with Ricci, who proved and illuſtrated in a happy manner ſeveral of his new theorems. In the year 1666 Ricci publiſhed a little work, entitled "Exercitatio Geometrica," &c. in which he determined, in a purely geometrical manner, the tangents, and the maxima and minima of curves, chiefly compared with conic ſections of the firſt order. This piece was reprinted by the Royal Society of London, as a treatiſe of the

the greateft utility; and it was warmly applauded by fome of the moft diftinguifhed mathematicians of the age. Having been induced to enter into the church, he relinquifhed his mathematical purfuits, and wholly devoted his attention to the affiduous ftudy of divinity, and the duties of his new profeffion. He filled feveral ecclefiaftical ftations, and, among others, thofe of fecretary to the congregation of indulgences and of relics, and of confultor of the holy office. In the year 1681, pope Innocent XI. raifed him to the purple; an honour which he wifhed to decline, but was compelled to accept by the pontiff's abfolute command. He poffeffed it, however, only for a fhort period, as he died in 1682, at the age of 64. One of his "Differtations" is preferved in cardinal Brancaccio's "Works;" another in Charles Dati's "Epiftola ad Philalethos;" and one of his "Letters" in the firft volume of the collection, entitled "Lettere Memorabili." Gen. Biog.

RICCI, SEBASTIAN, was born at Belluno, near Trevifano, in 1659; and having difcovered an early genius for painting, was conducted by his father to Venice, and placed as a difciple with Fred. Cervelli, a Milanefe artift of good reputation, with whom he ftudied for nine years. He afterwards improved his practice at Bologna, &c. by copying, and obtained the favour and patronage of Rannuccio, the fecond duke of Parma.

By the liberality of that prince, he was honourably maintained at Rome, ftudying the productions of the beft ancient and modern mafters; and there he formed that manner which diftinguifhes his productions, and exhibits a ready and fplendid invention, a free and mafterly handling of the pencil, with a full luxuriance of colour, which for a while raifed him into the higheft efteem, and confequently immenfe employment.

Having quitted Rome, he returned to Venice, where he was fo eagerly folicited for his paintings, that he had fcarcely time to take even neceffary refrefhment. His fame fpread through Europe, and he received an invitation to the court of the emperor at Vienna, to adorn the magnificent palace of Schoenbrun. From thence he was encouraged to vifit London, where he was immediately and inceffantly employed by the court, the nobility, and perfons of fortune. Here he remained ten years, with his nephew and co-adjutor, Marco Ricci, who painted fkilfully fcenes of architecture and landfcape. He acquired great wealth by the immenfe occupation he found; and then returned to Venice, where he paffed the remainder of his days till his 75th year, when he fhared the common fate of mortals.

Ricci was one of the few, comparatively fpeaking, who enjoy during their lives the utmoft extent of their fame. In his hiftory, that portion of renown which attaches to him died with him, or nearly fo. In fact, he was a machinift, one who, being converfant in the rules of art, and fkilful in the application of the means, dazzled where he could not inftruct, and deluded by ingenuity without judgment, and art without expreffion. His works are to be found in many of our great houfes, as well as thofe of his nephew. At Chelfea and at the Britifh Mufeum there are confiderable pictures of his painting, but they do not rife in efteem by continued obfervation; and yet, unfortunately, they had fufficient influence in their day to lead the artifts aftray from the contemplation and imitation of the works of Raphael, and the greater mafters of the Italian fchool.

RICCIA, in *Botany*, a cryptogamic genus of plants, named by Micheli after a Florentine Senator of his time, Peter Francis Riccio, Prefident of the Order of St. Stephen, Auditor of the Academy of Pifa, &c.; who feems to have been rather a patron, than a practical cultivator, of botanic fcience.—Mich. Gen. 106. t. 57. Linn. Gen. 566. Schreb. 766. Mart. Mill. Dict. v. 4. Schmidel. Ic. t. 44, 45. Hedw. Theor. 116. t. 29. Juff. 8. Lamarck Illuftr. t. 877.—Clafs and order, *Cryptogamia Hepaticæ*. Nat. Ord. *Algæ*, Linn. *Hepaticæ*, Juff.

Eff. Ch. Male, fcattered warts?

Female, Germen globofe, funk, with the *ftyle*, in the frond. *Capfule* expofed, globofe, crowned with the ftyle, of one cell. *Seeds* numerous, elliptical.

The genuine fpecies of this genus grow on the earth, flourifhing in the damp cold feafon of the year, and difappearing in hot dry weather. Hence they are fuppofed to be annual. Such are three of the Britifh fpecies; *R. glauca.* Linn. Sp. Pl. 1605. Engl. Bot. t. 2546; *R. minima.* Linn. Sp. Pl. 1605. Mich. Gen. t. 57. f. 6; and *R. cryftallina.* Linn. Sp. Pl. 1605. Dickf. H. Sicc. fafc. 15. 20. Mich. Gen. t. 57. f. 3.—Thefe form fmall glaucous patches on the ground, in fandy or moift places. The other two Britifh fpecies float in frefh water pools; *R. fluitans.* Linn. Sp. Pl. 1606. Engl. Bot. t. 251, whofe frond is forked and linear; and *R. natans.* Linn. Syft. Nat. ed. 12. v. 2. 708. Engl. Bot. t. 252, whofe inverfely heart-fhaped form, with copious linear ferrated fcales, like radicles, beneath, has a very peculiar appearance. Nothing is known refpecting the fructification of thefe two laft. *R. fruticulofa* of Dickfon is a *Jungermannia*, Engl. Bot. t. 2514, probably a variety of the *furcata*.

RICCIA, *La*, in *Geography*, a town of Italy, in the Campagna di Roma; 1 mile S.E. of Albano.

RICCIA, a town of Naples, in the Molife; 15 miles E. of Boiano.

RICCIARELLI, in *Biography*. See VOLTERRA, DANIEL DA.

RICCIOLI, JOHN-BAPTIST, a learned Italian Jefuit, and an eminent philofopher, aftronomer, and mathematician, in the 17th century, was born at Ferrara, a city belonging to the papal jurifdiction, in the year 1598. At the age of 16 he commenced his noviciate in the fociety of Jefus. When he had completed his courfe of academical ftudies, he was felected to teach fucceffively rhetoric, polite learning, philofophy, and fcholaftic divinity, in the Jefuits' colleges at Parma and Bologna. While he difcharged the duties of thefe appointments with great fuccefs and reputation, he devoted his leifure hours to the ftudy of geography, hydrography, chronology, experimental philofophy, and aftronomy. During the difpute which took place in his time, refpecting the correctnefs of the Gregorian reformation of the calendar, he inlifted himfelf among the advocates for the reform, and publifhed fome little pieces on the fubject at Bologna, under the name of Michael Manfredi. His principal attention, however, was occupied on productions of greater magnitude. He projected a grand work, which was to be divided into three parts, containing a complete fyftem of philofophical, mathematical, and aftronomical knowledge. The firft of thefe parts was given by him to the public in 1651, in two large and clofely printed volumes, folio, under the title of "Almageftum Novum, Aftronomiam Veterum, Novamque Complectens," &c. In imitation of the "Almageft" of Ptolemy, it prefents us with a collection of the difcoveries and improvements in aftronomical fcience, from the earlieft ages of antiquity to the author's own time. From a table of contents which is prefixed to this part, it appears that the fecond part was to be divided into five books, treating of trigonometry, or the doctrine of plane and fpherical triangles, aftronomical inftruments, the optical part of aftronomy, geography, and chronology; and the third part into ten boks, comprehending

hending obfervations of the fun, of the moon, of eclipfes, of the fixed ftars, and planets, with precepts, and tables of the primary and fecondary motions, and other aftronomical tables. But if thefe parts were completed, they do not appear to have been ever publifhed. In the year 1661 he prefented to the world his "Geographiæ et Hydrographiæ Reformatæ, Libri XII." in folio; and in 1665, his "Aftronomiæ Reformatæ, Tomi duo," folio, 2 vols. in one. The laft work which he publifhed made its appearance in 1669, under the title of "Chronologia Reformata, et ad Certas, Conclufiones Redacta," folio, 2 vols. in one. Father Riccioli died in 1671, when about 73 years of age.

RICCOBONI, Louis, a comic actor and writer, born at Modena in 1674, devoted himfelf to the theatre under the name of Lelio. In 1716 he came to France with his family, and diftinguifhed himfelf as the beft actor at the Theatre Italien. Religious motives induced him to quit the ftage in 1729; and he died in 1753, much efteemed for the decency of his manners, and his amiable difpofition. He was the author of a number of comedies, which had a temporary fuccefs, and which contain much comic humour. One of them, entitled "Les Coquets," was revived a few years fince. He alfo wrote "Penfées fur la Declamation;" "Difcours fur la Reformation du Theatre;" "Obfervations fur la Comedie et fur le Genie de Moliere;" "Reflexions Hiftoriques et Critiques fur les Theatres de l'Europe;" and "Hiftoire du Theatre Italien."

The "Hiftory of the Italian Theatre" of this author, in 2 vols. 8vo., publifhed in 1730 and 1731, and the "Reflections Hiftorical and Critical upon all the Theatres of Europe," which appeared in 1738, contain many judicious obfervations relative to the ftage in general, and, in the work firft mentioned, to the lyric theatre in particular.

Riccoboni, Marie Laboras de Mezieres, fecond wife of the preceding, was born at Paris in 1714. After her marriage, fhe became an actrefs on the Italian theatre, which fhe quitted with her hufband. She is known by feveral novels, written with much elegance of ftyle and refinement of fentiment. The principal of thefe are "Lettres de Miladi Catefby;" "Lettres de la Counteffe de Sancerre;" "Lettres de Sophie de Valiere;" "Erneftine;" "Lettres de Milford Rivers." She alfo tranflated Fielding's Amelia; and fhe appears to have had a predilection for England, in which the fcene of feveral of her novels is laid. She was in habits of intimate correfpondence with Garrick. The works of Madame Riccoboni were printed collectively in 10 vols. 12mo. Neufchatel, and 9 vols. 12mo. Paris. They rank among the moft elegant and ingenious of the clafs, and difplay much knowledge of the tender affections, and great decency joined to vivacity. Several of her novels have been tranflated into Englifh. She died in 1792, reduced by the troubles of the time to a ftate approaching to want.

RICE, in *Botany*. See Oryza.

Rice, in *Rural Economy*, the name of a plant cultivated in many parts of the Eaft, in South Carolina, in America, and alfo in Spain, Italy, and Piedmont. It is a plant that grows to the height of about two feet and a half, with a ftalk not unlike that of wheat, but fuller of joints, and with leaves refembling that of the leek. It branches out into feveral ftems, at the top of which the grain grows in clufters, and each of them is terminated with an ear or beard, and inclofed in a yellow rough hufk. When ftripped of this, they appear to be of an oval fhape, of a fhining white colour, and almoft tranfparent. It is probably a plant that cannot be cultivated in this climate, as the experiments faid to be made by fir Jofeph Banks, and detailed as below by a writer in the tenth volume of the Agricultural Magazine, feem to fhew. It is ftated, that the dry or mountain rice which he received laft year from the Board of Agriculture for trial, had been procured at a confiderable expence by fir John Murray, from the neighbourhood of Serinagur, a city in India, fituated at the foot of mount Imaus, where fnow lies till late in the fpring; and where the climate has been fuppofed to refemble that of England fufficiently to make it probable that the vegetable productions of the one would equally fucceed in the other country; he therefore confiders it as a duty owing to the patriotic exertions of fir John, to give the Board fome account of the refult of the trial of it, made at Spring-Grove, near Hounflow, in Middlefex. He adds, that it was not till near the end of May, when the famples, being of fix forts, were delivered out by the Board, and they were fown immediately, on the 21ft day of that month, on fix fmall beds in a garden, under the fhelter of a paled fence, in a fouth expofure. And the grains were fown very thin, in order that the progrefs of their vegetation might be better noted: in a very few days they appeared above ground. The feafon being warm, with a moderate fupply of rain, it was feldom neceffary to water them; however, when they appeared to flag, which generally happened after three or four dry days had taken place, they were well fprinkled with a watering pot. He fays, that in lefs than a month they had grown feveral inches high; each fort had acquired an appearance very different from the reft; fome were pale green, and had broader blades; fome were deeper coloured, and narrower in the blade; and one fort had a brown hue on the whole plant; and the bafes of the leaves in this kind were nearly black.

He further ftates, that during the month of Auguft, they tillowed much more than he has obferved any other corn to do; fo much fo, that although they had been fown very thin, they became a denfe, compact bed of plants: the blades in fome of the kinds ftanding as clofe, or clofer to each other, than the thickeft fown barley ever does. At the clofe of the month the blades were from a foot to eighteen inches high; the plants continued to tillow, each root having by this time produced from ten to twenty off-fets, but no fymptom of a rifing-ftem was at all obfervable. In the middle of September they had ftill continued to tillow, and the blades to ftrengthen, fo that fome of them were at leaft two feet long. As the frofts of the autumn were now nearly approaching, it became an object of fome importance to examine the ftate in which the plants really were, in order to afcertain the probability of their having produced ears, or poffibility of their having ripened corn, if they had been fown a month or two earlier.

The moft careful infpection was therefore made by diffection, but no traces could be found of the rudiment of a joint beginning to form itfelf on the crown of the root, or of the embryo of the glumes of the ear, which in all kinds of corn are firft difcernible in that part. He fays that about this period he was taken ill, and obliged to defift from obferving their future progrefs; but a froft foon after followed, which cut the blade down to the earth, and at once deftroyed all hopes of thefe kinds of rice producing grain in our climate; the quantity of the blade was however fo uncommonly great, that it is not impoffible, he thinks, it might be advantageous to fow it as food for cattle, for a very large proportion of ftock might certainly be maintained upon an acre of it. He concludes by obferving, that before the froft fets in, he had ordered a tuft of each kind of the rice to be tranfplanted into a pot, and placed in a hot-houfe, in order, if poffible, to afcertain the natural period of this grain; whether, like winter corn, it requires eight or nine months to come to perfection, or, like our Lent corn, arrives at the ſame period in five or ſix: but all of theſe died, notwithſtanding great attention was paid to them: ſome ſeed, however, which he had given to Mr. Lambert, ſucceeded better; it was ſown in his hot-houſe in the month of June, where it throve well, but did not produce ears till near Chriſtmas, a period of ſeven months, from whence it is probable, the grain would have ripened in leſs than two months from the time the ear appeared. It is eaſy to deduce that in the neighbourhood of Serinagur theſe kinds of rice are either ſown as winter corn, or the climate there is far better ſuited to promote the quick progreſs of vegetation than our's is. It was, when it produced ears, about three feet and a half high, and ſome of the ſtems had five joints, including the radical one: had it been in a more ſuitable climate, it would certainly have grown taller, for the flowers dropped off without producing ſeed.

It is however cultivated much in the Eaſt, as in China, as well as in the ſouthern parts of America; the method of which is thus deſcribed by Mr. Duhamel.

1. To haſten the ſprouting of the rice, it is put into baſkets, and ſoaked for ſome days in a ſtanding water. 2. When their rice-grounds are ſo ſoaked with water as to be quite like mud, they are ploughed with a buffalo yoked to a plough very ſimple in its make, having but one ſhare, one handle, and no wheels. 3. After a gentle rain, they break the clods with a kind of large hurdle, drawn by a large buffalo; the driver ſitting upon it to increaſe the weight. 4. The ground is cleared of all ſtones, and whatever roots are in it are pulled up by a ſtrong harrow, with great iron teeth. This inſtrument is drawn by a buffalo, and a man guides it by the help of two handles, like thoſe of a plough, upon which he leans hard. The earth is like mud, and partly covered with water during all this operation. 5. The earth is afterwards ſmoothed with a harrow, which has ſeveral rows of teeth. A man guides this harrow by its two handles, whilſt a buffalo draws it; and as faſt as its teeth form little channels in the ground, the water runs in and fills them up. 6. When the rice that was laid to ſoak has ſprouted, the ſeed is known to be good; and it is then ſown by hand, very thick, and as equally as poſſible. Only part of the ground is ſown in this manner, to furniſh plants for the reſt. The day after it has been ſown the points of the plants appear above the ſurface of the water; for the ground is overflowed all this time with juſt enough water to cover it. And it is added, that when the plants have acquired a little ſtrength, they are ſprinkled with lime-water, to deſtroy the inſects, and ſome of the weeds that would hurt them. For this purpoſe a ſmall baſket is faſtened to the end of a long handle, and dipt in the lime-water, which runs through it, and is conveyed over the plants. And the Chineſe have a great veneration for the firſt inventor of this method, which anſwers to our cuſtom of ſteeping wheat in lime-water, or manuring land with quick-lime. 7. Towards April, when the plants are grown ſtrong enough to cover the whole field, and look very green and even, the greateſt part of them is pulled up by handfuls, all the mud is carefully waſhed off their roots, and, being held at the ſame time as even as poſſible with one another, they are planted in tufts, pretty far aſunder, and in a quincunx form, in fields prepared on purpoſe for them. A ſerene day is choſen for this operation, which muſt be performed as quick as poſſible. This practice of the Chineſe is, he thinks, with reſpect to the common culture of rice, what the new huſbandry is with reſpect to the common culture of wheat. 8. The rice muſt be watered, which is always done in China by overflowing it. To this end, the rice-grounds are always near a rivulet, pond, or great pool of water, from which they are ſeparated only by a bank or cauſeway. If the water was higher than the rice-ground, a trench cut through the cauſeway would overflow it at once: but as it is generally lower, or on a level with the rice-ground, the neceſſary quantity is conveyed in pails or buckets, which are worked chiefly by the help of ropes. 9. Though a man cannot ſtep in theſe rice-grounds without being up to his knees, the Chineſe weed them three times in a ſummer, and that with ſuch care, that they pull up even the roots of every weed. 10. When the rice is ripe, which is known by its turning yellow, like wheat, it is cut down with a ſickle, made into ſheaves, and carried into a barn, where it is threſhed with flails pretty much like ours: the ſtraw is removed with pitch-forks and ſhovels, and the outer huſk of the grain is taken off by beating it with great wooden peſtles, or a kind of mallet, after which it is ſifted and winnowed: and, laſtly, to get off the under huſk, the grain is put between two mill-ſtones, which are worked by a lever faſtened to the upper one. But the two moſt remarkable circumſtances of this culture are, 1ſt, the care which the Chineſe take not to let their plants be too cloſe together, leſt they ſhould rob one another of their food; and 2dly, their weeding their rice-grounds three times in a ſummer, which anſwers the end of the hoeings recommended for the alleys between the beds of other grain, cultivated according to the horſe-hoeing huſbandry.

This plant is ſaid to have been lately cultivated with ſucceſs near Dumfries, by Mr. Charters; notwithſtanding the want of ſucceſs in the above trial, as well as by others in Cambridgeſhire. And it is not improbable, but that by degrees it may be ſo naturalized to the climate, as has been the caſe with many other plants, as to be cultivated without much trouble or difficulty, and thus contribute to the advantage of the country as an article of the grain kind. Rice forms an excellent kind of bread when incorporated with flour, as well as a good food for the feeding of different ſorts of animals of the poultry and other kinds.

Rice is much uſed as food in the Roman Catholic countries in time of Lent. The ordinary preparation is, by firſt ſteeping it in water, then boiling it in milk. Some make it into a ſort of farina, or flour, by pounding it in a mortar, after having firſt put it in hot water, and again waſhed it out in cold.

Among the common kinds of grain, rice is accounted the mildeſt and moſt nutritious, and is ſuppoſed to be particularly ſerviceable in dyſenteries and diarrhœas. It is leſs viſcous than wheat, or of leſs tenacity, when boiled with water.

The northern nations eat their fowls and other meats with rice and ſaffron. The Chineſe make a wine of rice, which is of an amber colour, and taſtes like Spaniſh wine, and ſerves them for their common drink. In ſome parts of Europe they alſo draw a very ſtrong brandy, or ſpirit, from rice.

RICE-*Balking*, in *Agriculture*, a provincial word applied to a method of ploughing, in which, according to Mr. Marſhall, the flag is always turned up towards the unploughed ground, the edge of the coulter paſſing cloſe to the edge of the flag laſt turned: whereas, in *ſlob-furrowing*, the flag is turned towards the ploughed ground, the coulter paſſing fifteen or ſixteen inches from the laſt ploughed furrow; into which, in this caſe, the edge of the flag hangs; and, in both caſes, a ſlip of unploughed ſoil, of a width nearly to that of the flag, is buried.

RICE-*Bird*, in *Ornithology*. See EMBERIZA *Oryzivora*.

RICE *Lake*, in *Geography*, a lake of Canada, having a portage of 11 miles to lake Ontario. It difcharges itfelf by the river Trent, into the head of the bay of Quinté.

RICEBOROUGH, a town of America, in Liberty county, Georgia, where the county courts are held. The county contains 6228 inhabitants.

RICERCARE, Ital. to feek; whence *ricercata*, a refearch, a flourifh, a prelude, an impromptu, a voluntary. See RESEARCH.

RICEYS, LES, in *Geography*, a town of France, in the department of the Aube, and chief place of a canton, in the diftrict of Bar-fur-Seine; 6, 7, and 8 miles S. of Bar-fur-Seine. The place contains 3842, and the canton 7875 inhabitants, on a territory of 167½ kiliometres, in 8 communes.

RICH, CAPE, a cape on the weft fide of Newfoundland, towards the north end, and is the N.E. part of the gulf of St. Lawrence, having the ifle of St. John, and fome other fmall ifles, to the N. This cape was the boundary of the French privilege of fifhing, which extended from hence northward, and round to cape Bonavifta.

RICH *Inlet*, a narrow channel between two fmall iflands near the coaft of North Carolina. N. lat. 34° 14'. W. long. 77° 52'.

RICHARD *of St. Victor*, in *Biography*, a celebrated divine and fcripture commentator in the 12th century, was a native of Scotland, who went to purfue his ftudies at the univerfity of Paris. Here he entered among the canons regular of St. Auguftine, at the abbey of St. Victor, and became a pupil of the famous Hugh, who, like him, derived his furname from the fame houfe. Under this mafter he affiduoufly ftudied the feveral branches of fcience, as far as they were then known, particularly theological and biblical literature; and he acquired great reputation by his proficiency, as well as the friendfhip of the moft eminent men in that feat of learning. In 1164 he was elected prior of his monaftery, where he died, in the year 1173, equally refpected for his virtues as for his learned attainments. His critical pieces are very accurate for the time in which he lived. His ftyle, however, is not very elevated; on which account his pious treatifes, though abounding in excellent matter, are greatly deficient in weight and energy. His works confift of critical obfervations and remarks on fome of the hiftorical parts of the Old Teftament, relating to the tabernacle and the temple of Solomon; allegorical and moral "Commentaries" on feveral of the Pfalms, the Song of Songs, and the Apocalypfe; queftions on certain difficult paffages of St. Paul's epiftles, and other parts of the bible; and numerous critical, doctrinal, and practical treatifes. The whole have been frequently printed in a collective form; and the beft edition is faid to be that of Rouen, in 1650, in 2 vols. folio.

RICHARD I., king of England, furnamed *Cœur de Lion*, fon of Henry II. by Eleanor Guienne, was born in the year 1157. As fecond fon he was invefted in the duchy of Guienne, and county of Poitou. In 1173 he united with his brothers, Henry and Geoffrey, in a rebellion againft his father, which was foon quelled, and forgiven by the reigning monarch. Richard was now fent to Poitou to reduce fome revolted barons, where he difplayed that martial fpirit for which he was afterwards celebrated, and on account of which he obtained his furname. Refufing to pay homage for the duchy of Aquitaine to his elder brother Henry, a war broke out between them in France, which their father found great difficulty in terminating. Henry foon after this died, and Richard, being now heir apparent, was required to refign Aquitaine to his youngeft brother, John. This he refufed, and new wars enfued. In 1189 he joined Philip Auguftus, king of France, againft his own father, and did homage to the French king for the poffeffions which he held on the continent. A war was the confequence of this unnatural junction, in which Henry was haraffed and worn out by Richard, while he found himfelf abandoned by his youngeft fon John. Henry died in July of the fame year, and was fucceeded in his throne by the fubject of this article. He is faid to have vifited his father's corpfe on the day after his deceafe, and expreffing great remorfe for his paft behaviour, charged himfelf with being his murderer. Richard was crowned at Weftminfter, received into his confidence the faithful fervants of the late king, and difcountenanced all thofe who had been abettors in his own rebellion. He fet at liberty his mother, queen Eleanor, who had long been in a ftate of confinement, and endeavoured to conciliate the affection of his brother John by grants of great extent in England and France. Richard, while prince, had taken the crofs along with his father; and now he had come to the crown, he was determined to give fcope to his martial talents in the Eaft. Having made the requifite preparations, he, in 1190, had an interview with Philip of France, who had alfo taken the crofs, at which, mutual conditions were agreed upon refpecting their cooperation in the expedition, and the peace of the kingdoms during their abfence. As a prelude to their enterprize, which, according to the opinion of the times, was regarded as extremely pious in its object and motives, Richard and his nobles, who had embarked in the fame caufe, exercifed their zeal in a horrible maffacre and pillage of the Jews in feveral of the principal towns, which was ended by a bonfire of the bonds which the Chriftians had entered into with this much injured people.

About the middle of the year, the kings of England and France muftered their forces, which amounted to 100,000 men in arms, in the plains of Vefelay, on the borders of Burgundy. Richard then proceeded to Marfeilles for embarkation, and in September the two monarchs met at Meffina, where they fpent the winter, in the courfe of which, diffentions arofe that were nearly breaking out into open hoftilities, but which ended in a new treaty, in which all differences were for the prefent adjufted. Richard had long been under engagements to marry Adelais, Philip's fifter; but an attachment which he had formed to Berengaria, daughter of Sanchez, king of Navarre, together with fome mifconduct of the French princefs, induced him to break the contract, in which it appears that Philip acquiefced. Eleanor arrived at Meffina with Berengaria; but Richard, without waiting to celebrate his nuptials, fet fail in April, 1191, with his fleet, which was foon difperfed by a ftorm. The king failed into Crete; but three of his fhips, with his intended bride, and his fifter, the queen of Sicily, on board, were ftranded on the coaft of Cyprus. The king of that ifland treated the unfortunate crews and the princeffes with great rigour, in revenge for which infult, Richard landed his army in the ifland, defeated the inhabitants in two battles, and reduced the king to the furrender of himfelf, his only daughter, and his fovereignty. In this ifland he confummated his marriage with Berengaria, and then embarked for Paleftine.

The fiege of Acre, celebrated likewife in modern times, which had been commenced two years before, was ftill carrying on by the relics of the emperor Frederic's army, with the other Chriftian adventurers who had at different times joined the banners of the crofs, while it was obftinately defended by a numerous Saracen garrifon, fupported by Saladin at the head of a powerful hoft in the field. The arrival of the two kings infufed new vigour into

into the befiegers, and feats of arms were performed under the walls, by Richard and Philip, efpecially by the former, who far furpaffed his rival in military enterprife. The city furrendered in July 1191, and immediately there were two competitors for the titular kingdom of Jerufalem, whofe claims were efpoufed by the rival kings. Philip, however, did not remain long in the Eaft; he returned home, leaving 10,000 men with Richard, who marched from Acre with the intent of reducing the other towns on the fea-coaft, while Saladin attended his motions, and gave him frequent affaults, which produced deeds of extraordinary valour on both fides, till at length a general engagement was brought on, in which, after both wings of the Chriftian army had been defeated, Richard in the centre, by the moft heroic exertions of bravery, and confummate military fkill, gained a complete victory. This was immediately followed by the poffeffion of Joppa, Afcalon, and other places which Saladin had deferted; and Richard advanced within fight of the holy city; but the greater part of the allies refufed to concur in the fiege of that capital, and he was obliged reluctantly to return to Afcalon. Here he concluded a truce with Saladin, on the condition that Acre, Joppa, and the other fea-ports of Paleftine, fhould remain in the hands of the Chriftians, and that they fhould enjoy full liberty to perform their pilgrimages to Jerufalem.

Richard now prepared to return home, where his prefence was abfolutely neceffary on account of the great diforders into which his kingdom was fallen. Previous to his embarkation, he terminated the conteft for the crown of Jerufalem, by concurring in the election of Conrad, and beftowing the conquered kingdom of Cyprus upon the difappointed competitor Lufignan. At this period, Conrad was murdered in the ftreets of Tyre by two emiffaries of the prince of Affaffins, commonly called the "old man of the mountain;" and although the deed was clearly traced to this fource, Philip was bafe enough to calumniate Richard as the author of it, in order that he might have an excufe for the defigns which he was carrying on againft him in Europe.

Richard fet fail from Acre in October, 1192. In the courfe of his voyage he was wrecked near Aquileia: thence he purfued his way through Germany, in the difguife of a pilgrim; but being difcovered near Vienna, he was arrefted by the orders of Leopold, duke of Auftria, and thrown into prifon. He was afterwards given up to the emperor Henry VI., who had been offended by him. When intelligence of this event reached England, queen Eleanor wrote repeatedly to the pope, reprefenting to his holinefs the fcandal and injuftice of felling and imprifoning the moft illuftrious champion of Chriftendom, whofe exertions for the common caufe were celebrated throughout Europe and Afia; and claiming, in behalf of the captive king, the protection of the holy fee. Her reprefentations were of no avail: Richard was kept in prifon, and loaded with irons; which afforded his rival, Philip, full opportunity for invading his dominions. He entered into a treaty with John, who readily took up arms againft his brother's government, while Philip was making himfelf mafter of great part of Normandy. Richard, in the mean time, fupported his misfortunes and indignities with the moft undaunted courage. The emperor, to juftify his own conduct, produced the royal captive before the diet at Worms, under a charge of feveral heinous offences; but Richard repelled the accufations with fo much fpirit and eloquence, that he carried the affembly with him, who loudly exclaimed againft his detention. At length he was liberated, on the condition that 150,000 marks fhould be paid as a ranfom. He arrived in England in March, 1194, to the great joy of his fubjects in general.

When Philip was made acquainted with Richard's deliverance, he wrote to John "to take care of himfelf, the devil being broke loofe." The property of John was immediately confifcated, and his caftle at Nottingham feized. Richard was recrowned at Weftminfter, in the prefence of William, king of Scotland; and he then began to raife money, that he might take revenge upon his inveterate foe, Philip of France. John threw himfelf at the feet of his brother, imploring, in the moft abject terms, his pardon. "I forgive him," faid the hero, "and hope I fhall as eafily forget his injuries as he will my pardon." In the enfuing war between Richard and Philip, the former gained fome advantages; but a truce fufpended farther hoftilities. A peace was terminated in 1196; but in the following year, the war was renewed, in which much cruelty was exercifed on both fides.

England, during this foreign contention, had been the fcene of much calamity, partly through difturbances occafioned by the exactions of a needy and rapacious government, and partly by the more grievous calamities of famine and peftilence. A lafting accommodation with France, as preparatory to another expedition to the Holy Land, was in agitation, when the reign and life of Richard were brought to a clofe through his avarice, which is thus related by Hume.

Vidomar, vifcount of Limoges, a vaffal of the king's, had found a treafure, of which he fent a part to that prince as a prefent. Richard, as fuperior lord, claimed the whole, befieged the vifcount in the caftle of Chalus, near Limoges, in order to make him comply with his demands. The garrifon offered to furrender, but Richard was determined on revenge; and as he was furveying the caftle with Marcadèe, leader of his Brabançons, he was ftruck by an arrow, aimed at him by Bertrand de Gourdon. The wound was not confidered as mortal: the place was affaulted and taken, and the whole garrifon executed, except Gourdon, who had wounded him, and who was referved for a more favage execution. By the unfkilfulnefs of the furgeon, the wound, which was at firft but flight, exhibited the moft dangerous fymptoms, and the king felt that his end was approaching. He fent for Gourdon, and afked him what had induced him to make an attempt upon his life; to which the man boldly replied, "You killed, with your own hands, my father and my two brothers, and you intended to have hanged myfelf: I am now in your power, and you may take your revenge, by inflicting upon me the fevereft torments; but I fhall endure them with patience, provided I can think that I have been fo happy as to rid the world of fuch a nuifance." Richard, ftruck with the magnanimity and reafonablenefs of the reply, and probably humbled and penitent by the near approach of death, ordered Gourdon to be fet at liberty, and a fum of money to be given him; but Marcadèe, unknown to the dying king, feized the unhappy man, caufed him to be flayed alive, and then hanged. Richard died in the tenth year of his reign, and the forty-fecond of his age, leaving no iffue behind him. The moft fhining parts of his character are his military talents. He loved glory, and chiefly military glory; and as his conduct in the field was not inferior to his valour, he feems to have poffeffed every talent neceffary for acquiring it. His refentments were high, and his pride unconquerable. He was diftinguifhed by all the good as well as bad qualities incident to an impetuous and vehement fpirit: he was open, frank, generous, fincere, and brave; but revengeful, ambitious, haughty, and cruel. His talents were confiderable

in

in the cabinet, as well as in the field. He was a passionate lover of poetry: some of his compositions in that line are said to remain; and he bears a rank among the Provençal poets and Troubadours, who were the first of modern Europeans that distinguished themselves by attempts of that nature.

Though the English pleased themselves with the glory which the king's martial genius procured them, his reign was oppressive and arbitrary, by the high taxes which he levied on them, and frequently without consent of the states, or great council. In the ninth year of his reign he levied five shillings on each hyde of land; and because the clergy refused to contribute their share, he put them out of the protection of the law, and ordered the civil courts to give them no sentence for any debts which they might claim. Twice in his reign he ordered all his charters to be sealed anew, and the parties to pay fees for the renewal. He established by law one weight and measure throughout the kingdom, which the mercenary disposition and necessities of his successor engaged him to dispense with for money.

Richard II., king of England, son of Edward the black prince, and grandson of Edward III., was born in 1366, and, on the death of his grandfather in 1377, he succeeded to the throne in his eleventh year. The chief authority of the state, at this time, was in the hands of his three uncles, *viz.* John, duke of Lancaster; Edmund, earl of Cambridge, afterwards duke of York; and Thomas of Woodstock, afterwards duke of Gloucester. A council of nine persons was now nominated to conduct the administration of government. The early part of the king's minority passed in wars with France and Scotland; the consequence of which was a formidable insurrection at home, produced by the taxes necessary for the public service. In 1381, the indecent conduct of a collector of the poll-tax at Deptford having provoked one Walter, by trade a tyler, to break his skull with a hammer, a flame was instantly kindled, which spread over Kent, and the neighbouring counties; so that, in a short time, a body of 100,000 men was collected on Blackheath. Their object was not merely to put an end to an arbitrary tax, but to free the country from the personal servitude to which the lower classes were, at that time, in a great measure subjected. On their approach to London, they sent a message to the king, requesting a conference. He met them on the bank of the Thames, but was unable to satisfy their demands. In the rage of disappointment, they burst into London, committed great devastation, and excited universal consternation. At length ample charters of freedom were granted to them, and a general pardon for all past offences. The insurgents now dispersed, but the principal leader, Wat Tyler, at the head of the Kentish men, remained in London, and was unsatisfied with the concessions granted by the monarch. He met the king in Smithfield, whom he addressed with much insolence, and making the most extravagant demands, Walworth, lord mayor of London, drew his sword and felled him to the ground. While the rioters stood astonished with the fall of their leader, the king, with great presence of mind, rode up alone, and exclaiming that he would be their leader, drew them off involuntarily into the neighbouring fields. The monarch would willingly have pardoned the insurgents, and confirmed to them the charters which had been extorted by force; but other insurrections being excited, his advisers caused him to revoke all the charters that had been extorted from him, and to issue commissions for the trial of the rioters, many of whom were executed.

Richard, when he was sixteen years old, espoused Anne, daughter of the late emperor Charles IV.; after this he began to exercise a very tyrannical spirit, notwithstanding the early promise of his reign, and he took the great seal from Scroop, who had refused to set it to certain extravagant grants of lands made to courtiers. A war with France and Scotland, and the ambitious projects of the duke of Lancaster, disquieted some succeeding years. In 1385 Richard marched with a large army into Scotland, and ravaged the country to Edinburgh and Perth, both which towns he burnt; in the mean time a Scotch army was making a destructive inroad into England. The duke of Lancaster being absent, prosecuting his claim to the crown of Castile, the king's younger uncle, the duke of Gloucester, a man of popular manners and dangerous ambition, became a leader of the opposition to the administration of the king's favourites. By his influence an impeachment was sent up to the lords against the chancellor; and though the king withdrew, with his court, to Eltham, he was intimidated into a dismission of his minister, who was afterwards stript of his estates, and committed to custody. The parliament now felt themselves strong enough to proceed to active measures, and they went so far as to divest the king of all his authority, by obliging him to sign a commission, appointing a council of regency, consisting of fourteen persons, to whom the sovereign power was transferred for a year. The king now, in the twenty-first year of his age, was reduced to a state of complete insignificance, but he held frequent consultations with his friends relative to the means of emancipating himself; and in the year 1387, making a progress to the north, he summoned a council of his friends at Nottingham, by which questions were proposed to the judges concerning the legality of the commission which he had been compelled to sign. They unanimously declared it to be a violation of the royal prerogative, and pronounced all who had joined in the execution of it, as guilty of a capital offence. The duke of Gloucester and his party began now to make preparations to maintain their cause by force of arms. Being by much the stronger party, they obliged the king to accept of terms, and at the ensuing meeting of parliament the five principals in the king's council were impeached, and condemned to death. The judges, who had given their opinion in favour of the king, were all found guilty of high-treason, but the punishment of death was commuted for imprisonment in Ireland during life. In 1389 Richard entered the council, and, in a resolute tone, observed, that he was of full age to take the government into his own hands: his enemies submitted, and he granted a general amnesty.

Several years of tranquillity ensued, and the return of the duke of Lancaster formed a counterbalance to the influence of the duke of Gloucester. In 1394 Richard visited Ireland at the head of an army, in order to settle the affairs of that island, which he accomplished, and then returned. Although no acts of notorious misgovernment had been committed by the king for a considerable period, yet his private character and mode of life tended to disgrace him in the eyes of his subjects. He was indolent and averse from business, and spent all his time in conviviality and amusement, admitting jesters and persons of the meanest rank and station to his intimacy, and laying aside all the proper dignity of rank. He was still governed by favourites, who were the real distributors of every grace from the crown, so that the king was little better than a cypher. By Gloucester and his party the most criminal designs were imputed to Richard, which led the king, by the advice and solicitation of his adherents, to apprehend the duke and his two accomplices, the earls of Arundel and Warwick. This plan was executed in 1397; the duke was sent over to Calais in close custody, while the earls were committed to prison. A parliament was then aſſembled, before which the culprits were impeached of high treaſon. Lord Arundel was condemned, and executed; the earl of Warwick was alſo convicted, and condemned to perpetual baniſhment. The duke of Glouceſter was ſaid to have died of an apoplexy, but it was ſoon diſcovered that he had been ſuffocated. Although the proceedings of parliament were favourable to the royal authority, yet much ill-will prevailed in the nation on account of its ſeverities, and troubles were continually breaking out among the nobles. A quarrel between the dukes of Hereford and Norfolk, ariſing from a charge brought by the former againſt the latter, of ſlanderous words ſpoken concerning the king, was the cauſe of the revolution that terminated the reign. Richard interpoſed his authority and baniſhed them both; but it was agreed, that both exiles might receive, by their attornies, any inheritance that ſhould fall to them during their abſence. In 1399, John of Gaunt, duke of Lancaſter, died, and his ſon, the duke of Hereford, became heir to his vaſt eſtates, which Richard, in defiance of the agreement, ſeized as property lapſed to the crown, and the attorney who claimed them for the duke was even condemned as a traitor. While the nation was full of diſcontent on account of this act of tyranny, Richard went to Ireland, and, during his abſence, Henry of Bolingbroke, as the duke of Hereford, invited by his numerous partiſans to make uſe of this opportunity, came over from France, and landed in Yorkſhire, and being joined by the earls of Northumberland and Weſtmoreland, and other men of rank, proceeded towards the ſouth, at the head of 60,000 men, pretending that their ſole intention was to recover the duchy of Lancaſter. The duke of York, who had been left regent of the kingdom, joined Henry; and Richard, having heard theſe facts, intended to withdraw into France. He was, however, taken and thrown into Flint caſtle, from whence he was taken to London. His depoſition being reſolved on, thirty-five articles of accuſation were drawn up againſt him, which, however informal, and many of them unjuſt, were conſidered as quite ſufficient to juſtify the meaſures taken againſt him, and Richard was depoſed Sept. 30, 1399. Henry at the ſame inſtant ſtood forth, and claimed the crown, which was without heſitation awarded to him. He declared that the life of the dethroned king ſhould be ſafe, and he was committed for ſafe cuſtody to the caſtle of Pomfret; but the uſual fate of depoſed monarchs ſoon awaited him. Indeed it was eaſy to foreſee that he would not long remain alive in the hands of ſuch barbarous and ſanguinary enemies. Hiſtorians differ with regard to the manner in which he was murdered. It was long the prevailing opinion, that ſir Piers Exton, and others of his guards, fell upon him in the caſtle of Pomfret, where he was confined, and diſpatched him with their halberts. But it is more probable, that he was ſtarved to death in priſon; and after all ſuſtenance was denied him, he prolonged his unhappy life, it is ſaid, for a fortnight, before he reached the end of his miſeries. This account is more conſiſtent with the ſtory, that his body was expoſed in public, and that no marks of violence were obſerved upon it. He died in the thirty-fourth year of his age, and the twenty-third of his reign. He left no poſterity, either legitimate or illegitimate.

All the writers who have tranſmitted to us the hiſtory of Richard, lived during the reigns of the Lancaſtrian princes; and candour requires, that we ſhould not give entire credit to the reproaches which they have thrown upon his memory. But, after making all proper allowances, he ſtill appears to have been a weak prince, and unfit for government, leſs for want of natural parts and capacity, than of ſolid judgment and good education. He was violent in his temper; profuſe in his expence; fond of idle ſhow and magnificence; devoted to favourites, and addicted to pleaſure; paſſions, all of them, the moſt inconſiſtent with a prudent economy, and conſequently dangerous in a limited and mixed government.

This prince lived in a more magnificent manner than perhaps any of his predeceſſors or ſucceſſors. His houſehold conſiſted of 10,000 perſons. He had 300 in his kitchen, and all the other offices were furniſhed in proportion. It muſt be remarked, that this enormous train had tables ſupplied them at the king's expence, according to the mode of that age. Such prodigality was probably the ſource of many exactions by purveyors, and was one chief reaſon of the public diſcontents.

Richard III., king of England, born in 1450, was the youngeſt ſon of Richard, duke of York. On the acceſſion of his brother, Edward IV., he was created duke of Glouceſter, and during the viciſſitudes in the early part of Edward's reign, he adhered moſt cloſely to him, and ſerved him with courage and fidelity. He is ſaid to have had a hand in the ſlaughter of Edward, prince of Wales, after the battle of Tewkeſbury, and to have been the author, if not the real perpetrator, of the murder of Henry VI. in the Tower, but the ferocity of his diſpoſition was in him united with deep policy and diſſimulation. He married, about the year 1473, Anne, the widow of the prince of Wales, already mentioned, who was daughter of Neville, the great earl of Warwick. His elder brother, Clarence, had married the other daughter, and a violent diſſention took place between them, on account of the diviſion of the property. Richard, who found Clarence an obſtacle to his views of aggrandizement, combined with the adverſaries of that unfortunate prince in accuſations which proved his deſtruction. On the death of Edward (ſee his article) in 1483, the duke of Glouceſter was appointed the protector of the kingdom. He immediately cauſed his nephew, the young Edward V., to be proclaimed king, and took an oath of fealty to him. There were at this time two great factions in the nation, of which the leaders were the duke of Buckingham and lord Haſtings. Both theſe courted the duke of Glouceſter, who pretended a ſteady friendſhip for each when apart, while he was purſuing ſchemes of the blackeſt ambition. His firſt object was to get rid of thoſe who were connected with the young king by blood; and after ſpending an evening in company with Rivers, Grey, and ſir Thomas Vaughan, he cauſed them to be arreſted the next morning, and committed to Pomfret caſtle, at the ſame time diſmiſſing all the king's attendants and ſervants. He ſhortly after cauſed the priſoners at Pomfret to be put to death without the form of trial; and on the very day of their execution, at a council held in the Tower, a cry of treaſon was raiſed by his order, on which a party of armed men entered, who ſeized the archbiſhop of York, the biſhop of Ely, lord Stanley, and lord Haſtings, of whom the three firſt were committed to cuſtody, while Haſtings was led to immediate death. After this, his next ſtep was to eſtabliſh, with or without evidence, the illegitimacy of Edward's children, to make way for himſelf on the throne. This he did by attacking the chaſtity of his own mother, who, he ſaid, had been true to her huſband only in the caſe of himſelf, and that to Edward and Clarence there were different fathers. Theſe pleas were zealouſly advocated by his adherents, and among others by Dr. Shaw, brother to the lord mayor of London, who dwelt upon them with much eloquence, in a ſermon which he preached at St. Paul's Croſs. The duke of Buckingham afterwards, in a ſpeech

ſpeech before the corporation and citizens of London, enlarged upon the title and virtues of the protector, and then put the queſtion to his audience, whether they choſe the duke of Glouceſter for king? On their ſilence, he repeated the queſtion with more importunity, and at length a few voices cried out "God ſave king Richard." This was conſtrued into a public declaration in his favour, and Buckingham, with the lord mayor, repaired to the protector with a tender of the crown. He firſt affected alarm and ſuſpicion, and then pretended loyalty to his nephew, and unwillingneſs to take ſuch a burden upon himſelf. At length he accepted the offer, and Richard was proclaimed king on the 27th of June 1483. The depoſed king and his brother were never more heard of, they were probably murdered in the Tower.

Richard was now extremely liberal towards thoſe who had been inſtrumental in the change, and took other methods to court popularity. He made a progreſs with a ſplendid retinue through ſeveral of the towns, and at York was a ſecond time crowned, on which occaſion he created his only ſon prince of Wales. He ſoon began to diſplay all the qualities of a moſt cruel tyrant, which ſo diſguſted the whole nation, that deſigns were formed to hurl him from the throne. A conſpiracy was excited againſt him, in favour of Henry, earl of Richmond, which he diſcovered and quelled. This failure appeared to ſeat the king more firmly on the throne, and he took advantage of his ſituation by calling a parliament, in which many good laws were paſſed, the progeny of Edward IV. were baſtardized, and the crown ſettled on himſelf and poſterity. The death of his ſon, ſoon after, was a ſevere ſtroke to him in the midſt of his proſperity, which was followed by that of his wife; the laſt was imputed, but without any evidence, to the effects of poiſon. To prevent a projected marriage between Elizabeth, the eldeſt daughter of his brother Edward, and the earl of Richmond, Richard determined to marry her himſelf; as this union would have been very detrimental to the earl's intereſt, he haſtened his preparations for another expedition to England, and in Auguſt, 1485, landed an army at Milford-haven. Richard, informed of the advance of his rival, took the field, and met him, with an army of nearly 15,000 men, at Boſworth, in Leiceſterſhire. The battle was fought on the 23d of Auguſt; in which the king, finding his ſituation deſperate, ruſhed againſt his competitor, ſlew his ſtandard-bearer, and was upon the point of encountering the earl himſelf, when he was himſelf ſlain. The body of Richard was found in the field, ſtripped naked, and carried acroſs a horſe to Leiceſter, where he was interred in the Grey friars' church-yard. Thus fell this hated tyrant, after having poſſeſſed the throne about two years and two months. The hiſtorians, ſays Hume, who favour Richard, maintain, that he was well qualified for government, had he legally obtained it; and that he committed no crimes but ſuch as were neceſſary to procure him poſſeſſion of the crown: but this is a poor apology, when it is confeſſed, that he was ready to commit the moſt horrid crimes that appeared to him neceſſary for that purpoſe; and it is certain, that all his courage and capacity, qualities in which he really ſeems not to have been deficient, would never have made compenſation to the people for the danger of the precedent, and for the contagious example of vice and murder, exalted upon the throne. In perſon, Richard has been repreſented as of ſmall ſtature, deformed, and of a forbidding aſpect, but it is probable that the deteſtation of his character has aggravated his bodily defects. His memory lives in popular tradition, as that of the moſt odious tyrant that ever filled the Engliſh throne. For the foregoing articles we are chiefly indebted to the hiſtories of Hume and Henry.

Richard, John, a French advocate and theological writer in the 17th and the early part of the 18th centuries, was born at Verdun, in Lorraine, about the year 1638. The firſt part of his education he received at Pont-à-Mouſſon, and was then ſent to Paris, where he ſtudied law and divinity. Afterwards he was admitted an advocate at Orleans; but more for the ſake of poſſeſſing the rank and privileges connected with that title, than from any deſign to practiſe at the bar. His inclination led him to devote his time and talents to the compoſition and publiſhing of ſermons. By his numerous productions of this deſcription he acquired celebrity. In the year 1700 he began to publiſh a compilation, under the title of "A Moral Dictionary, or, Univerſal Pulpit-Science," which, in 1715, was extended to 6 vols. 8vo. It conſiſts of ſtriking ſentiments and reaſonings on a great variety of ſubjects, ſelected from the works of French, Spaniſh, Italian, German, and other divines, arranged in alphabetical order.

RICHARDIA, in *Botany*, was named by Houſtoun, in honour of Richard Richardſon, M.D. F.R.S. who reſided on his own eſtate at North Bierly, Yorkſhire, and died at an advanced age, about the year 1740. His fortune rendering him independent of medical practice, as a maintenance, he beſtowed great attention on the botany of his own country, and his name occurs continually in the publications of the early part of the 18th century, as the correſpondent of Ray, Sloane, Dillenius, &c. He communicated ſeveral papers, on various ſubjects, to the Royal Society; none of them botanical; ſee Pulteney's Sketches, v. 2. 185.—Linn. Gen. 174. Schreb. 230. Willd. Sp. Pl. v. 2. 222. Mart. Mill. Dict. v. 4. Juſſ. 198. Lamarck Illuſtr. t. 254. Gærtn. t. 25. (Ricardia; Rel. Houſt. 5. t. 9.)—Claſs and order, *Hexandria Monogynia.* Nat. Ord. *Stellatæ*, Linn. *Rubiaceæ*, Juſſ.

Gen. Ch. *Cal.* Perianth ſuperior, of one leaf, in ſix deep, erect, pointed ſegments, half the length of the corolla. *Cor.* of one petal, funnel-ſhaped; limb in ſix acute, erect ſegments. *Stam.* Filaments ſix, very ſhort, inſerted into the tube of the corolla, alternate with its ſegments; anthers ſmall, roundiſh, between the ſegments. *Piſt.* Germen inferior, three-lobed; ſtyle thread-ſhaped, the length of the ſtamens, three-cleft in the upper part; ſtigmas obtuſe. *Peric.* none. *Seeds* three, obovate, gibbous, rounded at the outer ſide, angular at the inner, crowned with the calyx.

Obſ. Gærtner has obſerved that the calyx and corolla have ſometimes eight ſegments, with eight ſtamens.

Eſſ. Ch. Calyx in ſix ſegments. Corolla of one petal, funnel-ſhaped. Seeds three, crowned with the calyx.

1. R. *ſcabra.* Linn. Sp. Pl. 470. Willd. n. 1.—Gathered by Houſtoun at Vera Cruz.—A rough hairy plant, with the habit of a *Spermacoce.* The *ſtem* is tall, purpliſh, with oppoſite branches, its hairs curved downwards. *Leaves* oppoſite, crowded, ovate, pointed, entire, hairy, with many ſtraight, parallel ribs. *Flowers* encompaſſed with numerous hairy briſtles. *Calyx* briſtly.

RICHARDSON, Jonathan, in *Biography*, a painter, and a writer on the art of painting, was born about the year 1665. He was intended by his father for the law, but at twenty years of age was permitted to deſert that profeſſion, and follow the bent of his inclination for painting. He then became the diſciple of Riley, with whom he lived four years, and finally connected himſelf by marrying his niece. The degree of ſkill which he attained, by no means corre-

correfponded with the ideas he entertained of the art, which were certainly of a juft and elevated kind. There are, however, great ftrength, roundnefs, and boldnefs in the colouring of his heads, which are drawn and marked in the manner of Kneller, with freedom and firmnefs; though the attitudes in which they and his figures are placed, the draperies which clothe the latter, and the back-grounds from which they are relieved, are infipid and taftelefs. It is certainly a very curious circumftance, that, when he wrote with fo much fire and judgment, as is difplayed in his Effay on Criticifm, and the Science of a Connoiffeur, dived fo deep into the inexhauftible ftores of Raphael, and was fo fmitten with the native luftre of Vandyke, he fhould fo ill apply to his own practice, the fagacious rules and hints he gave to others. Full of theory, profound in reflections on the art, and poffeffed of a numerous and excellent collection of drawings, he appears to have poffeffed no portion of invention, as applicable to the painter's art, and drew nothing well below the head; plainly manifefting the peculiarity of tafte or feeling which leads to excellence in that profeffion.

Thus much, however, muft be faid of him, that when Kneller and Dahl were dead, he ftood at the head of the portrait painters in this country, and practifed in it fufficiently long to acquire a tolerable competency. He quitted his occupation fome years before his death, when Hudfon, who had married one of his daughters, maintained the family honours for a while. Richardfon himfelf, by temperance and tranquillity of mind, enjoyed a life, protracted amidft the bleffings of domeftic friendfhip, to the advanced age of eighty, and then died refpected and lamented. He had had, a fhort time previoufly, a paralytic ftroke that affected his arm, yet never difabled him from taking his cuftomary walks and exercife; and it was after having been in St. James's park, he departed fuddenly, at his houfe in Queen-fquare, on his return home.

The fale of his collection of drawings, in February 1747, lafted eighteen days, and produced 2060*l*.; his pictures about 700*l*. He left a fon, who painted and drew alfo, and who appears to have been a perfect pattern of filial reverence and affection.

Richardson, Samuel, in *Biography*, was born in 1689, in fome part of Derbyfhire, to which county his father had retired from bufinefs, which he had carried on in London. In very early life he was characterized for his love of reading, and while a mere boy, he difplayed the uncommon qualities of a tafte for letter-writing and female fociety. At the age of thirteen, he was fo much in the confidence of three young women, as to be employed by them in making draughts of letters to their lovers; and, at this early period, fuch were his fidelity and difcretion, that not one of them fufpected him to be the writer for the others. He was apprenticed to a printer, whom he ferved moft confcientioufly for the full term of feven years, ftealing from the hours allowed to reft and recreation, his opportunities for mental improvement. After the expiration of his apprenticefhip, he paffed feveral years as journeyman in a printing-office, and then fet up in bufinefs for himfelf. His habits of diligence and accuracy, and his honourable dealings, foon gained him employers and friends, and he was often applied to by bookfellers for making indexes, and writing prefaces and dedications. The immediate occafion of his becoming a novel-writer, was an application made to him by two bookfellers, to write for them a volume of letters in a common ftyle, on fubjects that might ferve as models for the ufe of thofe who had not the talent of inditing for themfelves. He extended the idea to the conveying of inftruction in thinking and acting upon important occafions; and in compofing fome letters for the falutary purpofe of teaching young women going out to fervice how to avoid the fnares that might be laid for their chaftity, a ftory which he had heard many years before of a real occurrence came into his mind, and became the parent of "Pamela." This work was publifhed in 1740, and was received with extraordinary applaufe by readers of all ranks. It brought the author into immediate notice; but his "Clariffa," of which the firft two volumes appeared in 1748, placed him in the firft rank of novelifts. "A tale fo varied by character, fo minutely developing the movements of the human heart, fo pathetic in its circumftances, and prefenting fo fublime and perfect an image of female purity, had never before been given to the public. The intereft it excited during its progreffive appearance, efpecially among female readers, was incredible, and the fate of no real perfonage could have agitated more bofoms than that of the fictitious heroine." Rouffeau, in fpeaking of it, afferts, that "nothing was ever written equal or approaching to it in any language." The "Hiftory of Sir Charles Grandifon," his concluding work, appeared in 1753, which was intended to give the world an example of a perfect man, uniting the fine gentleman and the Chriftian.

While he was advancing in the career of his literary fame, he was not inattentive to that improvement of his fortune which his affiduity and integrity in his profeffion fo well merited. His firft great public employment was that of printing the "Journals of the Houfe of Commons," in 26 vols. folio, which he obtained through the recommendation of his friend, Mr. Speaker Onflow. In 1754 he rofe to be mafter of the Stationers' company, and in 1760 he purchafed a half of the patent of law-printer to his majefty. He was twice married, and had feveral children, but four daughters only grew up to folace his declining years. He was the fubftantial valuable friend in difficulty, diftrefs, and ficknefs. He was moft exemplary in temperance both of body and mind, and in the faithful difcharge of every moral duty. He died at the age of feventy-two, and was interred by the fide of his firft wife in St. Bride's church. The writings of Richardfon, exclufive of the three novels above referred to, were of no great confequence. They are chiefly the "Familiar Letters" already noticed; an edition of "Æfop's Fables," with reflections. His "Correfpondence," felected from the original manufcripts, was publifhed in fix volumes, in the year 1804, with a biographical account of the author, by Mrs. Barbauld, to which the reader is referred for more particulars relating to Mr. Richardfon.

Richardson's *Bay*, in *Geography*, a bay on the S.E. coaft of Jamaica.

RICHAW, a town of Pruffia, in the province of Oberland; feven miles S. of Liebftat.

RICHBOROUGH, a hamlet, and a diftrict of land, in the parifh of Afh, lower half hundred of Wingham, lathe of St. Auguftine, and county of Kent, England, is fituated about two miles N.W. from the town of Sandwich. It is noted in hiftory as the fcite of the Roman poft which guarded the fouthern entrance of the Portus Rutupenfis, whence it derived its original name of Rutupium. The fortrefs which defended the northern entrance was called Regulbium; and is noticed under the article Reculver. This port, in Roman times, appears to have been the moft famous of any in Britain; for it is noticed in the writings of Lucan, Juvenal, and Aufonius; and alfo in thofe of Tacitus, Ammianus Marcellinus, and Orofius. It likewife occurs in the Geography of Ptolemy, in the Itinerary of of Antoninus, in the Index of the writer of Ravenna, in the Peutingerian Tables, and in the Notitia of the weftern empire. In thofe days the fcite of Rutupium was a fmall ifland, though at prefent it is a confiderable diftance within land. This is proved by the teftimony of many ancient writers; by the appearance of the furrounding country; and the fact of ftrata of fea-fand being difcovered by digging into its furface. The period when it was deferted by the ocean was probably between the fourth and fixth centuries, as about that time the name of Sandwich, which rofe on the ruins of the Rutupian haven, begins to be mentioned in ancient writings as a frequented port.

Richborough was anciently called *Rhutupiæ*, *Portus Trutulenfis*, or rather *Portus Rhutupenfis*, *Rhutupfis Portus*, *Rhutupiæ Statio*, and *Rhutubi civitas et portus*, among the Greek and Roman writers, by the Saxons denominated *Reptacefter*, and by others *Ruptimouth* and *Richberg*. After the Saxons had commenced their piracies on the coaft, the legio fecunda Augufta, which had been brought from Germany by Claudius, and had been for many years ftationed at Ifca Silurum, in Wales, was removed hither and commanded by an officer under the count of the Saxon fhore. Under the Saxons it was ftill confiderable, and the place in which king Ethelbert refided.

Much diverfity of opinion prevails among the learned as to the precife fituation of the Urbs Rutupiæ, fome identifying it with the caftle, and others placing it along the adjacent fhore, while a third clafs of writers fix it at Canterbury. Among thofe who efpoufe the laft opinion is the late bifhop Douglas, who has difcuffed the fubject with great learning and ingenuity, in a paper printed in the firft volume of the "Bibliotheca Topographica Britannica." With his view of the matter, indeed, we are ftrongly inclined to coincide; for it feems impoffible that the city could ftand within the narrow limits of the caftle, and there are no veftiges in its vicinity of foundations of extenfive buildings, a circumftance which could fcarcely have happened, if fuch buildings had ever exifted. Of the fortrefs itfelf, however, much yet remains to folicit the examination and excite the amazement of the antiquary. In form it appears to have been, when complete, a regular parallelogram; but the greater part of the eaftern wall is now deftroyed. The whole fcite exterior to the ramparts occupied fix acres, one rood, and eight perches of ground; and the area within the walls five acres, three roods, and eight perches. The walls were flanked by round projecting towers at the angles, and by fquare ones at irregular diftances along the fides. There are marks of two of thefe in the weft wall, and of two others, befides the Porta-Decumana, in the north wall, and of two more in the fouth wall; in which undoubtedly was a third, that has fallen down the bank. Thefe fquare towers, projecting about eight feet from the wall, were folid nearly eight feet from the foundation, above which they were hollow. In the main wall within thefe towers are four large, round, fmooth holes in a row, each about nine inches in diameter, and penetrating about eight feet into the fubftance of the main wall. Below thefe are fmaller holes, four inches in diameter, that run about ten inches into the wall; all which feem to have ferved for the infertion of beams, to fupport an apparatus of defenfive machinery. Within the area, towards the north-eaft corner, and beneath the furface of the ground, is a folid rectangular platform of mafonry 144 feet long, 104 feet wide, and 5 feet thick. It is compofed of bolders and coarfe mortar; and is covered on the upper fide with a coat of the fame fort of mortar to the depth of fix feet. In the centre of the platform is the bafe or foundation of a building in the fhape of a crofs, which rifes about five feet above the level of the platform. The fhaft of this crofs meafures 87 feet in length and 7½ feet in breadth; and its tranfverfe is 46 long and 22 wide. In the weftern wall of the caftle was a large opening, 34 feet wide, where, about five feet under the furface, is part of another platform, confifting of large fquare blocks of ftone, and meafuring 24 feet 11 inches in breadth. There is no appearance of any fuperftructure having been raifed from this foundation. Near the middle of the north wall is the oblique entrance, or "Porta-Decumana," which is narrow; and, from the holes remaining in the walls, feems to have been furnifhed with good timber defences. The exterior paffage, running parallel with the main wall, is about four feet and a half wide, having a channel at the bottom for carrying off water from the higher ground within the caftle. Many Roman coins and other antiquities have been difcovered as well within the area of the fortrefs, as in its vicinity; and at the diftance of about 460 yards from its fouth-weftern angle, the remains of a Roman amphitheatre are yet diftinctly vifible, though its banks are much mutilated and levelled by the operations of hufbandry. Leland informs us, in his Itinerary, that there was formerly "a lytle paroche chirch of St. Auguftine and an hermitage" within the caftle. The church was a chapel of eafe to that of Afh; and is mentioned as ftanding in the reign of Edward VI. Antiquities of Richborough and Reculver, abridged from the Latin of archdeacon Battely, Lond. 8vo. 1774. Bibliotheca Topographica Britannica, vol. i. 4to. Lond. 1780. Beauties of England, &c. vol. viii. by E. W. Brayley. King's Munimenta Antiqua, vol. iii.

RICHEA, in *Botany*, fo named by Mr. R. Brown, in memory of M. Riche, one of the naturalifts who accompanied the expedition in fearch of La Peroufe, and being in a confirmed confumption at fetting out, died in the courfe of the voyage. Labillardiere has dedicated a genus to this companion of his labours, but it proves no other than what Forfter had previoufly publifhed as CRASPEDIA; fee that article. Brown Prodr. Nov. Holl. v. 1. 555.—Clafs and order, *Pentandria Monogynia*. Nat. Ord. *Epacrideæ*, Brown.

Eff. Ch. Calyx membranous, fimple, in five deep fegments. Corolla of one petal, clofed, hood-like, fplitting tranfverfely; its abrupt bafe remaining. Stamens inferted into the receptacle, permanent. Five fcales under the germen. Capfule fuperior, of five cells. Receptacles feparate, pendulous from the top of the central column.

1. R. *dracophylla*.—Gathered by Mr. Brown, in Van Diemen's ifland. A *fhrub*, varying remarkably in ftature, being only eighteen inches high on the fummits of the mountains, but in woods at their fides becoming a fmall *tree*, of the height of ten feet. "It has altogether the habit of Labillardiere's *Dracophyllum montanum*, differing only in the fingular economy of the *corolla*, which however feems fufficient to mark it for a diftinct genus." *Brown.* Notwithftanding the opinion of this judicious author, we prefume to think his *Cyftanthe*, Prodr. Nov. Holl. v. 1. 555, fcarcely fufficiently diftinguifhed from the above. Their *corollas* and *capfules* agree; the only difference confifting in the foliaceous *calyx* of *Cyftanthe*, and its want of fcales below the *germen*. We feel the more difpofed to unite thefe genera, as there is but one known fpecies of either.

RICHEFORT, or RICCIAFORT, JOHN, in *Biography*, a Netherlandifh mufical compofer of confiderable eminence. He is placed by Walther in the middle of the fixteenth century; but he was certainly a compofer many years before that period, as we find his name not only in the second book of "Motetti della Corona," published at Fossembrone, 1519, and preserved in the British Museum, in which collection he was author of the fourth motet, "Miseremini mei;" but to a motet in a music-book, preserved at Cambridge, of Henry VIII. when prince of Wales. Glareanus says, that "great praise is due in our times to the vocal compositions of John Richefort." In the museum collection of French songs, in four, five, and six parts, printed in the Netherlands during the sixteenth century, there is one by this author for three tenors and a base, which, though it would be thought monotonous by modern ears, has great merit for the artful contexture of the parts, which are moving throughout in close fugue and imitation. The words, indeed, of these old songs are generally as rude and devoid of meaning as those of our own country, equally ancient; this, however, contains a general censure of indiscriminate urbanity.

RICHELET, Cæsar-Peter, a French writer, was born, in 1631, at Cheminon, in Champagne. He went, when young, to Dijon, where he superintended the education of the son of the marquis de Courtivron. About 1660 he went to Paris, was admitted an advocate, and began to plead at the bar. He became connected with d'Ablancourt and Patru, and acquired reputation from the attention he paid to the French language. In 1665 he was admitted to an academy of men of letters, which the abbé d'Aubignac had established at his own house. It appears that he was for some time placed about the dauphin, as one who might contribute to inspire that prince with the love of literature. He afterwards took up his abode in different parts of France, the enemies he made by his satirical disposition obliging him frequently to shift his residence. He died at Paris in 1698, at the age of 67. The principal work of Richelet is his "Dictionnaire François," of which the first edition was published at Geneva in 1680, 4to., and several have since been printed with additions. The last is that of the abbé Goujet, Lyons, 1759, 3 vols. fol. Richelet's Dictionary has been popular, though his orthography was much censured. He also published "Dictionnaire des Rimes;" "Les plus Belles-Lettres des meilleurs Auteurs François;" of this collection the best edition is that of Bruzen de la Martiniere, 1737, 2 vols. 12mo.; "A Translation of Garcilasso de la Vega's History of Florida;" and other works.

RICHELIEU, Armand du Plessis, a famous prime minister of France, born at Paris in 1585, was the son of Francis du Plessis Richelieu, grand provost of France, and captain of the guards to Henry IV. He was brought up to the church, and after studying at the Sorbonne, went to Rome. At the early age of 22, he was consecrated bishop of Luçon. Though he had obtained some distinction by his proficiency in scholastic theology, his great object was to make his way at court. He concealed, under polite and insinuating manners, a determined disposition, and a spirit of intrigue well suited to a female regency and a reign of favourites. The queen-mother, Mary of Medicis, in 1616 nominated him her grand almoner and secretary of state. On the fall of the marshal d'Ancre, his protector, Richelieu retired from court, and affected to employ himself in writing books of devotion, while he was upon the watch to recover his credit. This point he at length gained, by effecting an accommodation between the queen and her son Lewis XIII., and the new favourite de Lugnes rewarded his services by procuring him a cardinal's hat in 1622. After the death of Lugnes, the court and kingdom fell into disorder through the intrigues of the great, and the contentions of different parties, while all agreed in their defiance of the laws, and encroachments upon the supreme authority. A minister of equal talents and resolution was wanted to remedy these evils, and he existed in Richelieu. He had gained the confidence of the queen-mother, who recovered influence enough to introduce him into the council, notwithstanding the opposition of the other ministers, who feared him, and the repugnance of the king, who suspected his ambition, and was shocked with his licentious manners. In 1624 he found means to subvert all his rivals, and to possess himself of the whole authority of the crown.

The government, in his hands, soon assumed a tone of vigour and decision. He concluded the treaty of marriage between the prince of Wales and Henrietta, the French king's sister, in spite of the efforts of Rome and Spain, and equally disconcerted those courts by sending an army, and preventing the projected union with the Milanese. He next turned his arms against the French Calvinists, who, rendered disaffected by the frequent breaches of the treaties made with them, were become a kind of independent republic within the kingdom. Having first secured the friendship of Holland by pecuniary aid, he obtained the assistance of its fleet, and that of the English, against their brother Protestants of Rochelle, and expelled them from the isle of Rhé. It is acknowledged that the French monarchy dates from him its strength and independence. One of the principal enemies he had to contend with was Gaston, duke of Orleans, the king's brother. In consequence of a conspiracy entered into by this prince to assassinate the minister, and effect great changes at court, Richelieu arrested several of his confidents, and brought some of them to the scaffold. The danger he had incurred formed a pretext for giving him a body guard; and, by his pretended wishes to quit his station, he augmented his influence over his master. In 1627 war broke out with England, chiefly in consequence of the insolent vanity of the duke of Buckingham; and the Rochellers, with whom an accommodation had been made, were induced to favour the English. Richelieu thereupon resolved to reduce to submission a town which had long been the seat of an independent power, often leagued with the enemies of the kingdom; and after the duke of Buckingham had been obliged with disgrace to quit the isle of Rhé, Rochelle was invested on all sides. Richelieu in person took the command of the siege, and in order to prevent the arrival of succours by sea, he caused to be constructed a vast dyke in the ocean, by which all communication from abroad was cut off. This circumstance has given occasion to the cardinal's flatterers to compare him with Alexander before Tyre, and the work has been represented as one of the prodigies of his genius; but it was really that of the genius of the engineer Metezeau, and Richelieu only deserves the praise of adopting a bold design, and finding resources for putting it in execution. At length, after a noble resistance of eleven months, Rochelle submitted to famine; and the Protestants having lost their great bulwark, and all their other strong places, were rendered incapable of again acting as an armed party. It is to the credit of the policy and moderation of Richelieu that they were still allowed the free exercise of their religion.

In 1629 Richelieu received the patent of prime minister, and was nominated lieutenant-general of the army employed in the war in Italy, with powers so extensive, that the royal authority was reduced to a shadow. All that was great in the nation trembled before him. His foreign politics had chiefly in view the humiliation of the house of Austria; and by his treaty, in 1631, with Gustavus Adolphus, he enabled that great king to pursue those plans which brought the

the empire to the brink of ruin. Gaſton, duke of Orleans, in his retreat, with the duke of Lorraine, whoſe ſiſter he had married for his ſecond wife, plotted to excite a civil war for the expulſion of Richelieu, and his own return to conſequence. His intrigues were diſcovered, and all his partizans were declared guilty of treaſon. The duke of Lorraine was compelled to abandon him, and incurred the loſs of ſome of his ſtrongeſt places. Gaſton entered France with a ſmall body of troops, accompanied by the brave duke of Montmorenci, but was defeated at Caſtelnaudari. Montmorenci was taken priſoner, and expiated his crime on the ſcaffold. The queen-mother herſelf was put under arreſt, her ſervants were all ſent to the Baſtille, and ſhe finally ended her days in exile at Cologne. The king ſupported his miniſter in all theſe ſeverities, created him a duke and peer, and gave him the government of Brittany.

France had hitherto acted only as an ally to the Swedes in their hoſtilities againſt the houſe of Auſtria; but after their defeat at Norlingen in 1634, the cardinal thought it neceſſary to enter as a principal into the war; and forming an alliance with Holland, and the dukes of Savoy and Parma, he cauſed war to be declared againſt the king of Spain in 1635. Events were at firſt unfavourable to the French arms, but at length became more proſperous to France, and the enemy was driven from her territories; the public finances were, however, exhauſted, and recourſe was had to the creation of a great number of venal offices, and other objectionable meaſures, to raiſe the neceſſary ſupplies. The talents of a financier do not ſeem to have been among Richelieu's qualifications, and he himſelf gave an example of profuſion which increaſed the public diſcontent. No prime miniſter ever affected more ſtate and ſplendour. The daily expence of his houſehold was eſtimated at a thouſand crowns, a prodigious ſum at that period! His guards and attendants, his equipage and eſtabliſhment, were rather upon the ſcale of a ſovereign prince than of a ſubject, and he much ſurpaſſed his maſter in external pomp. Lewis betrayed a diſſatisfaction on this account, which probably induced Richelieu to make him a preſent of his palace, ſince called the Palais Royal. He incurred great perſonal danger in 1642, from a conſpiracy againſt his power and life, headed by Cingmars. (See his article.) The duke of Bouillon, and the duke of Orleans, entered into the plot, and negociations were opened with Spain for aſſiſtance. The good fortune of Richelieu produced a timely diſcovery of this treaſon, and Cingmars was beheaded. The duke of Bouillon was arreſted, but made his peace by reſigning his principality of Sedan. Gaſton furniſhed proofs againſt his aſſociates. The victim moſt worthy of compaſſion on this occaſion was the ſon of the illuſtrious de Thou, who was capitally condemned only for not revealing a conſpiracy which he diſapproved. Richelieu was at this time lying dangerouſly ſick at Taraſcon. He proceeded to Lyons by water, and was thence carried to Paris in a kind of chamber, borne on the ſhoulders of his guards, breaches being made in the walls of the towns through which he paſſed to admit him. It ſoon appeared that he had not long to live, and he prepared for the final change with great firmneſs. In receiving the ſacrament he declared, that in the courſe of his miniſtry, he had never any thing in view but the good of religion and the ſtate—a declaration which the public opinion did not ratify. He died in December 1642, at the age of 58, worn out with toil and anxiety; but he terminated his career with fortitude and ſerenity, that aſtoniſhed thoſe who had beheld the ſanguinary effects of his adminiſtration. Three mighty and ſucceſsful projects immortalize the period of his government. He humbled the turbulent ſpirits of the great, he ſubdued the ſtubborn zeal of the Hugonots, and he curbed the encroaching power of the houſe of Auſtria. Undaunted and implacable, prudent and active, no combinations of the powerful nobles could withſtand his vengeance; no intrigues could elude his penetration; while he exalted the throne, he controlled a ſovereign impatient to rule, and jealous of his authority; and while he extinguiſhed the liberties of the people, he eſtabliſhed among them diſcipline and order, and opened to them the paths to learning and renown. His own account of his public character is this: "I venture upon nothing till I have well conſidered it; but when once I have taken my reſolution, I go directly to my end; I overthrow and mow down all that ſtands in my way, and then cover the whole with my red mantle." He was fonder of power than money, yet he amaſſed a princely fortune, which he bequeathed to the king. He was the author of ſome ſplendid eſtabliſhments; he rebuilt the Sorbonne, founded the royal printing-houſe, the botanical garden, and the French academy. As a writer, he obtained ſome credit in the controverſy with the opponents of the Catholic church; the moſt famous of his ſuppoſed works is, his "Teſtament Politique," the authenticity of which has been the ſubject of warm controverſy .The letters of Richelieu are ſaid to be intereſting, of which the beſt edition is that of 1696, in two vols. 12mo. Gen. Biog. Hiſt. of France, three vols. 8vo. 1790.

Richelieu, in *Geography*, a town of France, in the department of the Indre and Loire, and chief place of a canton, in the diſtrict of Chinon; 11 miles S. of Chinon; deriving its name from cardinal Richelieu, its founder. The place contains 3600, and the canton 12,525 inhabitants, on a territory of 320 kiliometres, in 21 communes.

Richelieu, a river of Canada, iſſuing from lake Champlain, and firſt called "Chamblee," which name was changed by the French into Richelieu at fort Chamblee, and diſcharging itſelf into the river St. Lawrence, N. lat. 46° 1'. W. long. 72° 56'.

Richelieu *Iſlands*, a cluſter of ſmall iſlands in the river St. Lawrence, about 100 in number, 36 miles above Trois Rivières. N. lat. 46° 22'. W. long. 71° 7'.

RICHEMONT, a town of France, in the department of the Moſelle, on the Orne; 10 miles S. of Thionville.

RICHENBURG, a town of Bohemia, in the circle of Chrudim; 10 miles S.E. of Chrudim.

RICHENVEIR, a town of France, in the department of the Upper Rhine; ſix miles N.N.W. of Colmar.

RICHER, John, in *Biography*, a French aſtronomer and natural philoſopher in the 17th century, of whom little is known, till he was admitted a member of the Royal Academy of Sciences at Paris in the year 1666, under the title of aſtronomer to that body. About 1671, Lewis XIV. ſent him to the iſland of Cayenne in South America, for the purpoſe of making obſervations that might contribute to the improvement of aſtronomical ſcience. After three years he returned, and gave the reſult of his labours in his "Aſtronomical and Phyſical Obſervations made at the Iſland of Cayenne," which are inſerted in the ſeventh volume of the "Memoirs" of the Academy of Sciences. Caſſini ſpeaks of him with commendation in his "Elements of Aſtronomy." He died in the year 1696.

Richer, Claude, a learned prieſt and mathematician in the 18th century, was born at Auxerre in the year 1680. He was intended for the eccleſiaſtical profeſſion when very young, and was ſent to Paris for his education. Here he diſtinguiſhed himſelf in 1701, when only arrived to the years of manhood, by a work which he publiſhed, entitled "Univerſal Gnomonics, or the Science of Dialling," &c. After this he was ordained prieſt, and remained about ten years

years almoſt an entire ſtranger to men of letters, engaged in the religious education of the young. About the year 1730 his paſſion for mathematical ſtudies revived with great ardour, and he produced a work entitled "General Analyſis, containing New Methods of reſolving Problems of every kind, and of all degrees to infinity." This work was immediately adopted by the Academy of Sciences, and conſtitutes the eleventh volume of the "Memoirs." This volume was ſoon to be followed by three others; theſe, however, did not make their appearance, which was probably owing to a change in M. Richer's ſtudies. By an accidental peruſal of a fragment of Manetho, high prieſt of Heliopolis, in Egypt, he was induced to devote his whole attention to the moſt profound reſearches in ancient hiſtory. Notwithſtanding the obſcurity of this relic of antiquity, he conceived that he thoroughly underſtood it, and that it furniſhed him with a clue, by the aid of which he could unravel all the difficulties of ancient hiſtory, ſacred and profane. Under the influence of this perſuaſion, he laboured night and day in attempting to illuſtrate it, till he had produced two immenſe folio volumes, which no one would undertake to print. As a ſpecimen of his labours, he publiſhed "A Chronological Series of the Kings of Egypt, determined according to three ſimple Dynaſties, from the Fragment of Manetho." He died about the year 1756.

RICHERIA, in *Botany*, a genus dedicated by Vahl, to the much neglected memory of Peter Richer de Belleval, firſt profeſſor of Botany, as well as of Anatomy, at Montpellier, to whom Henry IV. of France committed the care of eſtabliſhing a public garden in that univerſity. This deſign was executed in the moſt ſkilful and ſplendid manner. Belleval publiſhed a catalogue of the garden in 1598, and a French treatiſe, in 1605, recommending an enquiry into the native plants of Languedoc. This laſt was accompanied by five plates, intended as a ſpecimen of a future work, for which he ſubſequently prepared a number of engravings, rude and ſtiff in execution, but exhibiting many rare ſpecies. He never lived to publiſh theſe, and the plates remained neglected in the hands of his family, till Gouan recovered them, and ſent impreſſions to Linnæus. At length Gillibert obtained the plates, and publiſhed them in 1796. The two pamphlets above-mentioned were republiſhed in 1785, by the celebrated and unfortunate Brouſſonet; along with a treatiſe on the White Mulberry, by Olivier de Serres, originally printed in 1603. Richer de Belleval lived to ſee his garden deſtroyed by the fury of civil war, and was beginning to reſtore it, when he died in 1623, aged 65. His nephew accompliſhed the reeſtabliſhment of the garden, on a more extenſive ſcale. M. Dorthes of Montpellier publiſhed, in 1786, Recherches ſur la Vie et les Ouvrages de Pierre Richer de Belleval, in which every thing, that could be collected on the ſubject, is recorded. Some writers erroneouſly mention Belleval as the firſt botaniſt who gave copper-plate figures of plants. This honour is due to Fabius Columna, whoſe *Phytobaſanos* appeared in 1592. We muſt not omit to mention, that Scopoli has named a genus *Bellevalia*, a name, or ſomething like it, which Belleval himſelf was fond of giving to the Lily of the Valley. Bruguiere, in 1775, called a Madagaſcar plant *Richeria*, but his genus has not been eſtabliſhed.—Vahl Eclog. v. 1. 30. Willd. Sp. Pl. v. 4. 1122. Mart. Mill. Dict. v. 4.—Claſs and order, *Polygamia Diœcia; Diœcia Pentandria;* or rather *Pentandria Monogynia.* Nat. Ord. *Euphorbiæ*, Juſſ.

Gen. Ch. Male, *Cal.* Perianth of one leaf, permanent, in four or five ovate, acute, downy ſegments. *Cor.* Petals four or five, roundiſh, the length of the calyx. Nectary four or five glands, at the baſe of the imperfect germen. *Stam.* Filaments four, five, or ſix, between the glands of the nectary, erect, longer than the calyx; anthers oblong, two-lobed, erect. *Piſt.* Rudiment of a germen ſuperior, conical, villous, ſtyle and ſtigma wanting.

Female, *Cal.* and *Petals* like the male. Nectary a rim round the baſe of the germen. *Stam.* none. *Piſt.* Germen ſuperior, ovate; ſtyle very ſhort; ſtigmas three, revolute, channelled above. *Peric.* Capſule coated, ovate, ſmooth and even, of three cells, with ſix valves, ſeparating at the baſe. *Seeds* ſolitary, pulpy-coated, pendulous from the top of the central column.

Eſſ. Ch. Male, Calyx four or five-cleft. Petals four or five. Nectary four or five glands, at the baſe of the imperfect germen. Stamens four or five.

Female, *Cal.* and *Cor.* like the male. Nectary a rim at the baſe of the germen. Style very ſhort. Stigmas three, revolute. Capſule coated, of three cells and ſix valves, ſplitting at the baſe. Seeds ſolitary, pulpy.

1. R. *grandis.* Vahl. Eclog. v. 1. 30. t. 4.—Gathered by Ryan, on the ſulphur mountain in the iſland of Montſerrat. A *tree* of a great ſize. *Leaves* alternate, ſtalked, oblong, acute, entire, coriaceous, ſmooth, veiny, ſix or ſeven inches in length; very much contracted at the baſe. *Spikes* axillary, ſolitary, longer than the footſtalks, lax. *Capſule* the ſize of a hazel-nut. The diſcoverer of this rare tree is ſaid to have found ſome of the *flowers* perfect as to *ſtamens* as well as *piſtil.* Hence, notwithſtanding the ſlight differences in the *nectary*, we ſhould incline to place the genus in *Pentandria Monogynia.*

RICHFIELD, in *Geography*, a town of America, in Otſego county, New York, taken from Otſego townſhip, and incorporated in 1792.

RICHFORD, the north-eaſternmoſt townſhip of Franklin county, Vermont, ſituated on Miſſiſcou river; containing 442 inhabitants.

RICH-HILL, a poſt-town of the county of Armagh, Ireland; 62 miles N.W. from Dublin, and four miles E. from Armagh.

RICHLAND, a diſtrict of South Carolina, bounded S. and S.W. by Congaree and Broad rivers, and E. by Wateree river, which divides it from Kerſhaw and Clermont counties.—Alſo, a townſhip of Bucks' county, in Pennſylvania, containing 1317 inhabitants.

RICHMAN'S ISLAND, a ſmall American iſland on the coaſt of Cumberland county, in the ſtate of Maine; four leagues N. from Wood iſland and one league W. of Portland. Few veſſels put in here, except coaſters. Wood iſland is in N. lat. 43° 50′. W. long. 69° 37′.

RICHMOND, a borough and market-town in the wapentake of Gilling-Weſt, north riding of Yorkſhire, England, is ſituated on the banks of the river Swale, at the diſtance of 48 miles N.W. from York, and 293 miles N.N.W. from London. It was anciently much celebrated for its caſtle, which was founded by the firſt earl of Richmond, Alan, ſon of Hoel, count of Brittany. This nobleman, who was nearly related to William, duke of Normandy, accompanied that prince in his expedition to England; and in reward for his ſervices, received from him all the forfeited eſtates of the brave Edwin, earl of Mercia. This grant was made during the time William was engaged in the ſiege of York, and is peculiarly remarkable on account of its brevity. Alan immediately after married Hawiſe, the conqueror's daughter; and being thus loaded both with riches and honour, built the caſtle, and part of the town of Richmond, to protect his family and his eſtates againſt the diſinherited and outlawed

outlawed Englifhmen in thofe parts. Having no iffue by his lady, the earldom of Brittany devolved to Conan le Groffe, his fon by a fecond wife; and Alan, furnamed the Black, fon of Hawife by a former hufband, obtained the earldom and eftates of Richmond. During the reigns of our Norman kings this title and property were poffeffed by feveral different families, fome of whom were allied to the blood royal, both of England and France. Edward III. conferred the eftate on his third fon, John of Gaunt, who afterwards furrendered it in exchange for fome other lands. The fame monarch gave Richmond, with his daughter, in marriage to John, earl of Montford and duke of Brittany, who was furnamed the Valiant. During the wars of York and Lancafter, both the title and the eftates feveral times changed poffeffors, and at length were vefted in the crown by the acceffion of Henry, earl of Richmond, to the throne, under the title of Henry VII. By his fucceffor, Henry VIII., Richmond was conftituted a duchy in the perfon of his natural fon, Henry, who died without iffue in the year 1535.

The town of Richmond is comparatively limited in extent and population; containing, according to the late parliamentary returns, only 512 houfes, and 3056 inhabitants. Its fine fituation, however, and the character of its buildings, which are in general conftructed of ftone, give it a dignified and interefting appearance. It occupies the top and declivity of a lofty eminence boldly rifing from the river Swale, which winds round the town and the caftle in a femicircular direction. The chief trade of this place is that of knit woollen ftockings, in which men, women, and children, are employed. The market day is Saturday, weekly; and there are befides four annual fairs. The market here is one of the largeft in the north of England for corn; and the fairs are noted for a great fupply of horfes, horned cattle, and fheep. Richmond is a borough by royal charter, and fends two reprefentatives to parliament, who are elected by "thofe perfons who are owners of ancient burgages in the faid borough, having a right of pafture in a common field, called Whitecliff pafture." The government of the town is vefted, by the charter of queen Elizabeth, in a mayor, recorder, twelve aldermen, twenty-four common council-men, and other inferior officers. The petty feffions for the wapentake of Gilling-Weft are holden here.

The caftle of Richmond ftands on the fouth fide of the town, on a bold eminence, overlooking the Swale, which runs in a deep valley beneath. On all fides the approach to it is fteep and difficult, except on the north, where the afcent is gradual. The caftle is now in a very ruinous condition, but it ftill retains the features of former grandeur and importance. The keep-tower, of which the fhell is nearly entire, is of great altitude; and its exterior walls are more than eleven feet thick. The lower ftory is fupported by a vaft column of ftone in the centre, from which fpring circular arches clofing the top. The ftaircafe only reaches to the firft chamber, the reft of it being dilapidated, as the floors of the two upper rooms are fallen in. In this keep is a well of excellent water. The ruins of feveral other parts of this caftle yet remain. In the fouth-eaftern corner of the area is a ruinous tower, below which is a dungeon, about fourteen feet deep. The ground covered by this fortrefs meafures nearly fix acres in extent, and is the property of the duke of Richmond and Lennox.

The country around Richmond is extremely picturefque, and affords feveral objects of intereft to the tourift and the antiquary. Clofe to the town, on the north, are the remains of a houfe of Grey friars, which was founded, in 1258, by Ralph Fitz-Randal, lord of Middleham; and adjoining is the fcite of a nunnery, now totally demolifhed. About a mile to the eaftward are the fine ruins of St. Agatha abbey, feated on the banks of the river Swale. This monaftery was eftablifhed, in 1151, by Roaldus, conftable of Richmond caftle, and at the time of the reformation maintained feventeen monks of the Premonftratenfian order. Richard Scroope, chancellor of England, was a great benefactor to this monaftery; for befides his manor of Brumpton-upon-Swale, he granted 150*l.* a-year for the fupport of ten additional regular canons, two fecular canons, and twenty-two poor men. Near this priory ftood an hofpital, which being decayed in the reign of Henry VI. was reftored by William Ayfcough, one of his judges, to whom he had given the patronage of it. A cell for Benedictines, dependent on the abbey of St. Mary of York, was fituated on an eminence in this neighbourhood. It was founded, in 1100, by Wymer, chief fteward to the earl of Richmond. Many other religious foundations occupied the banks of the Swale, which our limits forbid us to enumerate. The circumftance of the waters of this river having been held facred, on account of the baptifm of 10,000 Saxons near Catterick, by bifhop Paulinus, in 627, gave occafion to this multiplicity of religious foundations. Catterick is fituated at the diftance of five miles from Richmond; and is fuppofed by feveral antiquaries to be the fcite of the Roman Cataractonium, or Cataracton, mentioned in the Itinerary of Antoninus. Dr. Gibfon, however, fuppofes that ftation ftood between the village and the river, and fome extenfive Roman remains, on the fpot, he defcribes, feems to juftify his conjecture. This ftation continued for fome time a Saxon town; but was totally deftroyed at an early period by the Danes. The Roman road here divides itfelf into two branches, one of which leads to Caldwell, diftant about eight miles from Richmond, where veftiges of a large town may yet be traced. The Roman name of this ftation is unknown. A Tour in Scotland 1772, by Thomas Pennant, efq. 4to. Lond. 1790. Beauties of England and Wales, vol. xvi. by John Bigland.

Richmond, a village and parifh in the hundred of Kingfton, and county of Surrey, England, is fituated on the fouth bank of the river Thames, at the diftance of ten miles W.S.W. from St. Paul's cathedral, London. It is a fpot of great celebrity, both on account of the beauty of its fcenery, as well as from having been the fcite of a royal palace during feveral centuries. The firft authentic mention of the manor here occurs in the reign of king John, at which time it was denominated Sheen, and was the property of Michael Belet, who held it by the fervice of being the king's butler. In the reign of Edward I. it reverted to the crown, and has fince been generally poffeffed either by the king, or fome branch of the royal family. At what precife period the original royal palace was erected is uncertain; for though Edwards I. and II. refided for fome time in the manor-houfe, it does not appear to have been a ftructure entitled to that appellation. Edward III. is faid to have built a palace on his "maner of Shene;" but Manning, the author of the "Hiftory and Antiquities of Surrey," inclines to the opinion, that he only improved and enlarged the former building. Be this as it may, it had undoubtedly become a fixed regal refidence in the reign of that monarch, who died here the 21ft of June, 1377; as did queen Anne, the confort of his fucceffor, Richard II. in the year 1394. The latter prince was fo much affected by his lofs, that he abandoned the palace, and fuffered it to fall to ruin; or, as others affert, pulled it down. From this period Sheen remained in a neglected ftate, till the acceffion

of

of Henry V. to the throne, when the palace was rebuilt in a ſtyle of greater magnificence than before, and in ſuch a manner, as to render it "a delightful manſion of curious and coſtly workmanſhip, and befitting the character and condition of a king." Of Henry VI. we diſcover no traee here, nor does it appear that Edward IV. ever occupied the palace; but it is recorded, that he granted it, in the ſixth year of his reign, to his queen, Elizabeth, to be held by her during her life. Henry VII. gave the cuſtody of the manor to Robert Skeene; and on the death of his own mother-in-law, the queen dowager, in 1486, took poſſeſſion of the palace, which he frequently made his reſidence. In 1492 he held a grand tournament here, at which ſir James Parker, in a controverſy with Hugh Vaughan, for right of coat of armour, was killed in the firſt courſe. Seven years ſubſequent, the king being then at the palace, it was ſet on fire by accident, and almoſt totally deſtroyed. Henry, however, ſoon replaced it by another, which was built in a ſtyle of much "magnificence and elegance;" and on this occaſion changed the name of the manor to Richmond, in reference to his own title before he obtained the crown. The picture of Henry V. and his family, the marriage of Henry VI. and that of Henry VII. in the Strawberry-hill collection, are ſuppoſed to have been painted for this monarch, and intended for the palace of Richmond. It had been finiſhed only a ſhort time, when another fire broke out, which did conſiderable damage. One of the newly erected galleries alſo fell in the ſame year, only a few minutes after the king and his ſon had been walking in it. Philip I., king of Spain, was entertained here with great magnificence in the year 1506; and king Henry VII. died here 21ſt April, 1509. His ſucceſſor kept his Chriſtmas at Richmond the year ſucceeding his acceſſion to the throne; and on the 12th of January enſuing a tournament was held in the park, when the monarch himſelf, for the firſt time, took a part in the exerciſes. Charles V. was lodged at Richmond in the year 1523. King Henry VIII. had a ſon of his own name born here, who died when ſcarcely two months old. Queen Elizabeth was impriſoned in the palace by her ſiſter, queen Mary; and after ſhe was ſeated on the throne, it became one of her favourite places of reſidence. In her reign, Eric IV., king of Sweden, was lodged here, and here ſhe herſelf ended her days, on the 24th of March, in the year 1603. In the autumn of the ſame year the ſeveral courts of juſtice were removed hither from London to avoid the plague, which was then raging with great vehemence in the capital. Henry, prince of Wales, reſided here in 1605, and in 1625 the courts were a ſecond time adjourned to Richmond for the ſame reaſon as before mentioned. Charles I. was frequently at this palace, where he formed a large collection of pictures. In 1636 lord Buckhurſt, and lord Edward Sackville, performed a maſk before his majeſty and his royal conſort. When the ſame monarch was in Scotland, the parliament ordered that the young prince ſhould be ſent to Richmond with his governor, probably biſhop Duppa, who is ſaid to have educated Charles II. at this place. In the month of June, 1647, the palace was prepared for the king's reception, but he is generally ſtated to have refuſed to go to it. Mr. Lyſons, however, quotes a newſpaper of the 29th of Auguſt in that year, as mentioning that the prince elector was then at Richmond, and that the king, with the duke of York, hunted in the New Park, and killed a ſtag and a buck. During the commonwealth, the palace was ſold by the commiſſioners of the houſe of commons, who ordered a ſurvey of it to be taken, as it then exiſted. From this document we learn, that the great hall meaſured 100 feet in length, and 40 in breadth; and that it had a ſcreen at one extremity, and a turret or clock-caſe, covered with lead, at the other. The ſame record deſcribes the privy lodgings as a free-ſtone building, three ſtories high, and ſurmounted by fourteen turrets. A "canted tower," with a ſtaircaſe of 124 ſteps, is likewiſe noticed; alſo a chapel 96 feet long, and 40 broad; and a privy garden, with an open gallery 200 feet in length, over which was a cloſe gallery of the ſame extent; but no mention is made of a library, though a French writer aſſerts, that a royal library was eſtabliſhed at Richmond by Henry VII. and the librarian is enumerated among the officers of this palace in the houſehold eſtabliſhments of queen Mary and queen Elizabeth. The ſurvey further mentions three pipes, which ſupplied the palace with water, one from the white conduit in the New Park, another from the red conduit in the town-fields; and a third from a conduit near the alms-houſes, which are ſituated cloſe to the river. The materials of the palace are there valued at 10,782*l.* 19*s.* 2*d.* It was purchaſed by Thomas Rookeſby, William Goodrick, and Adam Baynes, on behalf of themſelves and other creditors, and ſhortly after reſold by them to ſir George Norton, who had been one of the commiſſioners appointed to ſit in judgment on Charles I. On the reſtoration, this gentleman having been deprived of his eſtates by confiſcation, Richmond palace was beſtowed on the queen mother, but it is probable, that at this period it was in a very diſmantled ſtate. Indeed Fuller, who wrote ſoon after the reſtoration, ſpeaks of it as pulled down; but this could not literally be the caſe, as it ſeems to have been inhabited ſubſequent to his day. Now, however, it is totally demoliſhed, except a few of the out-offices, and its ſcite is occupied by ſeveral houſes, which are held on leaſe from the crown. One of theſe, the property of the late duke of Queenſberry, was built by the third earl of Cholmondeley, who ornamented it with a very fine collection of pictures. The tapeſtry, which hung behind the earl of Clarendon in the court of chancery, ſtill decorates the hall of this manſion. The firſt mention made of a park at Richmond is in the reign of Edward I. This is the park which, in the time of Henry VIII. was called the Old or Great Park, in contradiſtinction to another adjoining, called the New Park, which had been formed by the predeceſſor of that monarch. The lodge belonging to it was for ſome months the reſidence of the celebrated cardinal Wolſey, after he had loſt the favour of his capricious and tyrannical maſter. Charles I. having formed a third park of far greater extent than both the former ones united, they appear to have merged into one ſoon after, as in the ſurvey taken in 1649, only two parks are mentioned, *viz.* that lately incloſed by the monarch, called the New Park, and another ſtyled the Little or Old Park. This laſt was valued at 220*l.* 3*s.* *per annum*, and was purchaſed by William Brome of London for 7048*l.* The lodge already mentioned was afterwards poſſeſſed by ſir Thomas Jervaſe, and the park by ſir John Trevor, in leaſe from the crown, to which the whole manor reverted at the reſtoration. King William afterwards granted the lodge, together with the ſtewardſhip of the manor, to John Latton, eſq., who held them till the death of that prince. In 1707, they were granted by queen Anne to James, duke of Ormond, who rebuilt the lodge, and reſided there till his attainder in 1715, when he privately withdrew to Paris. By act of parliament, paſſed in 1721, the earl of Arran, his brother, having been enabled to purchaſe his eſtates, king George II., then prince of Wales, bought this of Richmond from him, and frequently retired hither, even after his acceſſion to the throne.

throne. His queen, Caroline, was very partial to the ſpot, and had a dairy and menagerie here; ſeveral ornamental buildings were alſo diſperſed by the ſame princeſs throughout the gardens, in one of which, called the Hermitage, ſhe placed the buſts of Newton, Locke, and other eminent literary characters. His preſent majeſty frequently reſided here in the early part of his reign; and was ſo ſtrongly attached to the place, that he ordered the old lodge to be demoliſhed with the view of building a magnificent palace on its ſcite, which, however, has never riſen above the foundation; but an obſervatory has been erected at a ſhort diſtance from it, according to deſigns furniſhed by ſir William Chambers. Here is a mural arc of 140 degrees and eight feet radius; a zenith ſector of twelve feet; a tranſit inſtrument of eight feet; and a ten-feet reflector by Herſchel. On the top of the building is a moveable dome, which contains an equatorial inſtrument. Part of the Old Park forms a grazing and a dairy farm in his majeſty's own occupancy. The remainder conſtitutes the royal gardens, which were firſt laid out by Bridgeman, and afterwards altered to their preſent improved ſtate by Brown. The other park, *viz.* the New or Great Park, made by Charles I. met with great oppoſition to its formation, and may be reckoned among the impolitic meaſures of his reign. It was preſented to the common council of London by the parliament; but was reſtored to the crown in 1660. The rangerſhip of this park is conſidered an office of high dignity and truſt, and has been frequently held by a female branch of the royal family.

Within Richmond pariſh were anciently ſituated ſeveral religious houſes. Edward II. founded here a convent of Carmelite friars, and endowed it with an annual income of 120 marks out of his exchequer; but only two years after its eſtabliſhment he removed the monks to Oxford. Henry V. alſo founded here a houſe for the maintenance of friars of the Carthuſian order, whom he incorporated by the name of the Houſe of Jeſus of Bethlehem, at Shene. The foundation charter deſcribes it as built on the north ſide of the palace; and it appears from records to have been a ſtructure of great extent and magnificence. At the diſſolution its annual revenues were eſtimated at 962*l.* 11*s.* 6*d.*, and ſhortly after its ſcite was granted to Edward, earl of Hertford. A third convent was erected here by Henry VII. about the year 1499, and filled with friars of the Franciſcan order. This eſtabliſhment was ſuppreſſed in 1534, but its value is not recorded.

Richmond church is dedicated to St. Mary Magdalen, and conſiſts of a nave, two aiſles, and a chancel, built of bricks, with a ſquare embattled tower at the weſt end, conſtructed of ſtone and flints in chequers. The principal monuments here are thoſe of Henry, lord viſcount Brounker, cofferer to king Charles II.; admiral Holborn; ſir Matthew Decker; lady Chaworth, relict of ſir Richard Chaworth, who died in 1689; lady Howard, relict of William lord Howard of Eſcrick; James Thompſon, author of the "Seaſons;" and that of Mrs. Yates, the celebrated actreſs, who died in 1787. This church is in the dioceſe of Wincheſter, and in the deanery of Ewell. According to the parliamentary returns of 1811, the pariſh contains 875 houſes, and 5219 inhabitants. Hiſtory and Antiquities of the County of Surrey, by the late Rev. Owen Manning, S.T.P. continued by William Bray, eſq. of Shire, fol. vol. i. 1804. Salmon's Antiquities of Surrey, 8vo. 1732. Lyſons's Environs of London, vol. i. 4to. Maurice's Richmond, a poem, 4to.

Richmond, a townſhip of America, on the W. line of Maſſachuſetts, in Berkſhire county; 17 miles W. by S. from Lenox, and 150 W. of Boſton. Iron ore of the beſt quality is found here; but as it lies deep, it is raiſed at a great expence. It abounds with lime-ſtone, and coarſe, white, and clouded marble. It was incorporated in 1775, and contains an iron-work, three griſt-mills, a fulling-mill, two ſaw-mills, with 1041 inhabitants.—Alſo, a townſhip of Cheſhire county, New Hampſhire, on the Maſſachuſetts line, about 11 miles E. of Connecticut river, and 97 W. by S. from Portſmouth. It was incorporated in 1752, and contains 1290 inhabitants.—Alſo, a townſhip in Waſhington county, Rhode iſland, ſeparated from Hopkington on the W. by Ward's river, a branch of Paucatuck river. It is diſtant about 19 miles W. of Newport, and contains 1330 inhabitants.—Alſo, a county of New York, comprehending the whole of Staten iſland; which ſee.—Alſo, a county of North Carolina, in Fayette diſtrict, bounded S. by the ſtate of South Carolina, and N. by Moore county. It contains 6695 inhabitants. The chief town is Rockingham. The S.E. part of the county is a continued plain, covered in many places by pines, and moſtly inhabited by Scotſmen. The upper part has hills and vallies. In the middle and eaſt parts large tracts remain uncultivated. The inhabitants, with regard to religion, are Preſbyterians, Baptiſts, Methodiſts, and Quakers. Their houſes are logs, covered with ſlabs.—Alſo, a county of Virginia, bounded N. and N.E. by Weſtmoreland, and S. and S.W. by Rappahannock river, which ſeparates it from Eſſex county. It contains 6214 inhabitants. The court-houſe is 273 miles from Philadelphia.—Alſo, the preſent ſeat of government of the ſtate of Virginia, ſituated in Henrico county, on the N. ſide of James' river, at the foot of the falls, and containing between 400 and 500 houſes; built partly on the bank of the river ſo as to be convenient for trade, and partly upon an eminence that overlooks the lower part of the town, and commands an extenſive proſpect of the river and country. The new houſes are well built, and the ſtate-houſe is on the hill. In this town is an elegant ſtatue of the illuſtrious Waſhington, executed at Paris. The lower part of the town is divided by a creek, over which is a convenient bridge. Another bridge of curious conſtruction connects the city with Mancheſter. The public buildings, beſides the ſtate-houſe, are an epiſcopal church, a court-houſe, gaol, theatre, and three tobacco warehouſes. At the W. end of the town are ſeveral mills. Near the mills are a diſtillery and brewery. The falls above the bridge are ſeven miles in length. A noble canal is cut on the N. ſide of the river, which terminates in a baſin of about two acres, in the town of Richmond. Richmond is 626 miles from Boſton, 374 from New York, 176 from Baltimore, 278 from Philadelphia, 247 from Fayetteville, 497 from Charleſton, and 662 from Savannah. N. lat. 37° 40′. W. long. 77° 50′.—Alſo, a county of the upper diſtrict of Georgia, in which is ſituated the city of Auguſta; it is ſeparated from South Carolina on the E. by Savannah river, and contains ſix towns and 6189 inhabitants.—Alſo, a townſhip in Chittenden county, Vermont, eſtabliſhed in 1794: it contains an excellent tract of land, and lies on both ſides of Onion river. It has 935 inhabitants.—Alſo, a town, or rather village, in the iſland of St. Vincent, in the Weſt Indies; ſituated at the head of a deep bay, on the W. ſide of the iſland. Chateaubelair river runs on the S. ſide of the town, which gives name to the bay. Another river on the N. ſide of the town empties into the bay.—Alſo, a townſhip in Lenox county, Upper Canada, N. of Fredericksburgh in the bay of Quinte, and watered in front by the river Appennie.

Richmond *Bay*, a bay on the N. coaſt of the iſland of St. John, in the gulf of St. Lawrence.

RICHOLD, or RICHELD, a town of France, in the department of the Roer, near the Meufe; two miles N.W. of Dalem.

RICHTENBERG, a town of Anterior Pomerania; 28 miles E.N.E. of Roftock. N. lat. 54° 11′. E. long. 12° 50′.

RICHTENSWYL, a town of Switzerland, fituated on the W. fide of the lake of Zurich, in the canton of Zurich, with a convenient harbour; 11 miles S. of Zurich.

RICHTER, FRANCIS-XAVIER, in *Biography*. There are fix muficians, male and female, recorded in Gerber's Continuation of Walther's Lexicon; among whom, the moft celebrated and beft known in England was Francis-Xavier, whofe works, of various kinds, have great merit. His harmony is correct; the fubjects are often new and noble; but his detail and manner of treating them are frequently dry and fteril, and he fpins and repeats paffages in different keys without end. The French and Italians have a term for this tedioufnefs, which is wanting in our language, they call it *rofalie*, or *rofalia*; derived from the name of a female faint, remarkable for repeating her "Pater nofter," and ftringing her beads more frequently than even St. Dominic himfelf, or than any other pious perfon, that has merited a place in the Golden Legend. An Italian cries out, upon hearing a ftring of repetitions, either a note higher, or a note lower, of the fame paffage or modulation, *ah fanta Rofalia!* Indeed this fpecies of iteration indicates a want of invention in a compofer, as much as ftammering and hefitation imply a want of wit or memory in a ftory-teller. He died at Strafburgh in 1789, in the 80th year of his age.

RICIMER, count and patrician of the Weftern empire, and an important civil and military character in the fifth century, ferved from his youth in the Roman armies, in which he acquired great reputation by his warlike exploits, and at length came to be regarded as the ableft commander of the age. In the reign of the emperor Avitus, being one of the chief commanders of the Barbarian troops which formed the defence of Italy, he deftroyed, in the year 456, on the coaft of Corfica, a fleet of Genferic, the Vandal king, deftined to ravage the coafts of Gaul or Italy. His fuccefs in this inftance enabled him to avail himfelf of the public difcontent to depofe Avitus, and raife Majorian to the throne in the year 457. Not being raifed to the dignity which he expected under this prince, he compelled him to abdicate the purple, which act was foon followed by his death. Ricimer next raifed an obfcure man, named Libius Severus, to the throne, who bore the title of emperor during four years without performing any one imperial function. In that period, and in an interregnum of two years more, Ricimer exerted fovereign authority, amaffing treafures, forming a feparate army, and negociating alliances. His own mean birth prevented him from affuming the purple, and in 467 he concurred in the inauguration of Anthemius, whofe daughter he married. The new emperor and his fon-in-law paffed fome years in union, but at length diffentions broke out between them, which ended in the murder of the emperor, and Olybrius was proclaimed in his ftead. Thus a third, or perhaps a fourth, emperor was added to the number of Ricimer's victims; but in a few weeks after the maffacre of Anthemius, "Italy," fays Gibbon "was delivered by a painful difeafe from the tyrant Ricimer, who bequeathed the command of his army to his nephew Gundobald, one of the princes of the Burgundians." Gibbon's Rom. Hift. vol. vi.

RICINA, in *Ancient Geography*, an ifland fituated on the coaft of Hibernia, being one of thofe called Ebudes, according to Ptolemy and Pliny.—Alfo, a town of Italy, in the Picenum, which became a Roman colony under the reign of the emperor Severus. It was fituated S.W. of Auximum.—Alfo, a town of Italy, in Liguria, S.E. of Genoa.

RICINOCARPODENDRON, compounded of *ricinus*, καρπὸς, *fructus*, and δενδρον, *arbor*, in *Botany*, the name of a genus of plants, eftablifhed by Dr. Amman, the characters of which are thefe: the flower is of the rofaceous kind, confifting of three petals, difpofed in a circular order, in the centre of which there arifes a large and open tube, through which fhoots up the piftil, which grows at the bottom of the cup; this piftil, finally, becomes a trigonal fruit, divided into three cells within, and containing each one feed in a rough coat.

The leaves of this tree fometimes refemble thofe of the afh, being compofed of three or four pairs of fmaller leaves joined to a middle rib, thefe are not ferrated, and terminate in a fharp point; the flowers grow at the alæ of the leaves, they are white, and are difpofed in lax fpikes; the fruit is green at firft, afterwards it becomes of a yellowifh-red, and finally fcarlet; it is of the bignefs of a walnut, and in fhape much refembles the fruit of the ricinus; the covering of the feeds is black on the outfide, and red within, and each feed is divided into two lobes; when ripe, the fruit burfts, and the feeds fall out. It is a native of the Eaft Indies. Act. Petropol. vol. iii. p. 214.

RICINOCARPOS, from the refemblance of the fruit to *Ricinus*. See ACALYPHA, CROTON, MERCURIALIS, TRAGIA.

RICINOIDES. See CEANOTHUS, CROTON, JATROPHA.

RICINUS, fo denominated from the refemblance its feed has to the little infect called *a tick*, *Ricinus*; and this, according to Ainfworth, is compounded of *re* and *canis*, becaufe the tick, or tyke, is particularly annoying to dogs, by fixing itfelf upon their ears and other parts. It is the Κικι or Κροτων of Diofcorides, words expreffive of the likenefs of its feed to the above-named infect; the former of thefe appellations, however, is of eaftern origin, and of rather uncertain fignification, occurring in the prophet Jonah. Pliny mentions an Egyptian herb called *Palma-Chrifti*, with feeds like a tyke.—Linn. Gen. 503. Schreb. 655. Willd. Sp. Pl. v. 4. 564. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 331. Purfh v. 2. 602. Tournef. t. 307. Juff. 388. Lamarck Dict. v. 6. 200. Illuftr. t. 792. Gærtn. t. 107. Loureir. Cochinch. 584.—Clafs and order, *Monoecia Monadelphia*. Nat. Ord. *Tricoccæ*, Linn. *Euphorbiæ*, Juff.

Gen. Ch. Male, *Cal.* Perianth inferior, of one leaf, cloven into five, ovate, concave fegments. *Cor.* none. *Stam.* Filaments very numerous, thread-fhaped, united unequally below into various fets; anthers twin, roundifh.

Female on the fame plant with the male, *Cal.* Perianth inferior, of one leaf, deciduous, cloven into three, ovate, concave fegments. *Cor.* none. *Pift.* Germen fuperior, ovate, covered with awl-fhaped briftly bodies; ftyles three, cloven, erect and fpreading, hifpid; ftigmas fimple. *Peric.* Capfule roundifh, three-furrowed, generally prickly all over, of three cells and three valves. *Seeds* folitary, nearly ovate.

Eff. Ch. Male, Calyx five-cleft. Corolla none. Stamens numerous. Female, Calyx three-cleft. Corolla none. Styles three, cloven. Capfule three-celled. Seed folitary.

Obf. Willdenow divides this genus into two fections; the firft containing fuch fpecies as have *palmate leaves*, the fecond thofe which have fimple, *undivided leaves*.

Sect. 1. *Leaves palmate.*

1. R. *communis*. Common Palma-Chrifti, or Caftor-oil Plant. Linn. Sp. Pl. 1430. Woodv. Med. Bot. 171. t. 61.—Leaves peltate; lobes lanceolate, ferrated. Stem herbaceous, pruinofe. Stigmas three, cloven at the tip.—Native of the Eaft and Weft Indies. Firft cultivated in England, as appears from Turner's Herbal, in 1562. It flowers in July and Auguft. *Root* biennial or annual, long, thick, and fibrous. *Stems* round, thick, jointed, channelled, glaucous; of a purplifh-red colour upwards. *Leaves* large, deeply divided into feven fegments, on long, tapering, purplifh ftalks. *Flowers* in long, green, and glaucous fpikes, fpringing from the divifions of the branches; the males form the lower part of the fpike, the females the upper. *Seeds* ovate, fhining, black dotted with white.

The prefent fpecies is fubject to confiderable variations. In our gardens it is a ftrong, luxuriant, fhrubby annual. In Africa it becomes a tree. Clufius obferved it in Spain, with a trunk as large as a man's body, and fifteen or twenty feet high. And Ray faw it in Sicily as big as our common Elder-trees, woody and long-lived. From the feeds of this valuable plant is extracted the *oleum ricini*, or caftor-oil, fo important for its medicinal properties as a gentle, though moft effectual, cathartic.

2. R. *viridis*. Green Palma-Chrifti. Willd. n. 2. Hort. Berol. v. 1. t. 49.—Leaves peltate; lobes oblong, toothed, the midddle one flightly three-lobed. Stem herbaceous, pruinofe. Stigmas fix.—Native of the Eaft Indies, flowering at Kew, in Auguft. Very like the laft, but always annual, with a taller and fomewhat lefs pruinofe *ftem*. *Leaves* larger, and not fo diftinctly palmate.

3. R. *africanus*. African Palma-Chrifti. Willd. n. 3. (R. communis; Desfont. Atlant. v. 2. 355.)—Leaves peltate; lobes oblong, ferrated. Stem fhrubby, fmooth.—Native of the north of Africa. *Stem* arboreous, or rather fhrubby, not pruinofe. *Leaves* fmaller than in the preceding. *Stigmas* fix, or more properly three, cloven down to the bafe.

4. R. *lividus*. Dark-leaved Palma-Chrifti. Willd. n. 4. Jacq. Ic. Rar. t. 196. Mifc. v. 2. 360.—Leaves peltate, coloured; lobes oblong, ferrated. Stem fhrubby, fmooth, coloured.—Native of the Cape of Good Hope, whence it was introduced at Kew in 1795. A *tree* ten feet or more in height. *Stem*, during the firft year, blood-red and fhining, afterwards woody and thick, afh-coloured and ftreaked. *Leaves* divided into eight or ten lobes, of a dark blood-red colour, on long, glandular ftalks. *Flowers* green. *Fruit* of a livid colour, with long, foft prickles. *Seeds* fhining, variegated with black and brown.

5. R. *inermis*. Smooth-fruited Palma-Chrifti. Willd. n. 5. Jacq. Ic. Rar. t. 195. Mifc. v. 2. 362.—Leaves peltate; lobes oblong, ferrated. Stem fhrubby, pruinofe. Capfules without prickles.—Native both of the Eaft and Weft Indies. In habit much refembling the laft, but altogether ftouter. *Stem* brown, fpotted with dark purple. *Leaves* very large, on long ftalks. *Fruit* ovate, rugofe, dark green.

6. R. *fpeciofus*. Beautiful Palma-Chrifti. Willd. n. 6. Burman. Ind. 207. t. 63. f. 2.—Leaves peltate, inclining to digitate; leaflets lanceolate, ferrated.—Native of Java. We know not that this is any where defcribed or figured, except as it occurs in the above authors.

Sect. 2. *Leaves fimple, or undivided.*

7. R. *Tanarius*. Scollop-leaved Palma-Chrfti. Linn. Sp. Pl. 1430. (Tanarius minor; Rumph. Amboin. v. 3. 190. t. 121.)—Leaves peltate, ovate, pointed, wavy, toothed.—Native of the Eaft Indies, and woods of Cochinchina. It flowers at Kew, from July to September. A middling fized *tree*, with twifted, fpreading *branches*. *Leaves* on long ftalks, fcattered, fragrant. *Flowers* in long, fimple, terminal clufters.

8. R. *dioicus*. Dioecious Palma-Chrifti. Willd. n. 8. Forft. Prodr. 67.—Leaves heart-fhaped, pointed, nearly entire. Flowers dioecious. Capfules muricated.—Native of Tanna ifland. This *fhrub* has round, fmooth, brown *branches*, the younger ones white with down. *Leaves* alternate, entire, or very obfcurely toothed; fmooth above with downy veins; refinous and dotted beneath. *Female flowers* in fmall, axillary, ftalked *clufters*. *Bractea* folitary, ovate, pointed, very large, at the bafe of every flower.

9. R. *globofus*. Globular Palma-Chrifti. Willd. n. 9. (Croton globofum; Swartz Ind. Occ. v. 2. 1181.)—Leaves ovate, obtufe, entire. Flowers dioecious. Capfules globular.—Native of lofty mountains in Jamaica. A branched, erect *fhrub*, four or five feet high. *Branches* round, ftriated, afh-coloured. *Leaves* alternate, ftalked, coriaceous. *Flowers* in terminal, fhort, erect *clufters*. *Capfule* roundifh, the fize of a pea.

10. R. *integrifolius*. Simple-leaved Palma-Chrifti. Willd. n. 10.—Leaves ovate, pointed, entire, coriaceous.—Native of the Mauritius. Adopted folely on Willdenow's authority, who defcribes it as "a *fhrub* with round, brown, fmooth, divided *branches*. *Leaves* fmooth, on channelled ftalks two or three inches long. *Clufters* axillary. *Flowers* and *Fruit* unknown. It appears to be dioecious."

Ricinus, in *Gardening*, contains plants of the tall, herbaceous, tender, annual kind, of which the fpecies cultivated is the common palma-Chrifti (R. communis).

This plant becomes a tree in its native fituation, and the feeds afford the caftor-oil of the fhops.

And there are feveral varieties of it, as the great American palma-Chrifti, which has brown ftalks that divide into two or three branches, and rife fix or feven feet high; the leaves are broader, and not fo deeply divided; they are of a deep green on both fides, and are unequally ferrate. The fpikes of flowers are fhorter, the feed-veffels rounder and of a brownifh colour, and the feeds are much lefs, and brown. This fort is a native of the Weft Indies.

Alfo the green-ftalked American palma-Chrifti, which has a thick herbaceous ftem, of a greyifh-green, with the joints not fo far afunder as in the preceeding fort: it rifes about four feet high, and is divided at the top into three or four branches, which fpread out almoft horizontally; the leaves are large, of a deep green on their upper fide, but greyifh on their under; they are deeply cut into fix or feven (fometimes eight) lanceolate fegments, which are unequally ferrate: the petioles fpread out more horizontally than thofe of the common fort, and are much fhorter: the principal ftalk and branches are terminated by loofe fpikes of flowers; the covers of the capfules are green, and clofely armed with foft fpines; the feeds are fmaller and lighter coloured than thofe of the preceding fort. This is alfo a native of the Weft Indies.

Likewife the wrinkled-capfuled palma-Chrifti, which rifes with an herbaceous ftalk about four feet high; the lower part is purplifh, and the upper deep green, the joints pretty far afunder; the leaves are of a deep green on their upper fide, but paler underneath; they are not fo deeply divided as fome of the others, and are more regularly ferrate; the fpikes of flowers are large; the males have more ftamens, with yellow anthers; the capfules are oval and wrinkled,

 but

RICHOLD, or RICHELD, a town of France, in the department of the Roer, near the Meuſe; two miles N.W. of Dalem.

RICHTENBERG, a town of Anterior Pomerania; 28 miles E.N.E. of Roſtock. N. lat. 54° 11′. E. long. 12° 50′.

RICHTENSWYL, a town of Switzerland, ſituated on the W. ſide of the lake of Zurich, in the canton of Zurich, with a convenient harbour; 11 miles S. of Zurich.

RICHTER, FRANCIS-XAVIER, in *Biography*. There are ſix muſicians, male and female, recorded in Gerber's Continuation of Walther's Lexicon; among whom, the moſt celebrated and beſt known in England was Francis-Xavier, whoſe works, of various kinds, have great merit. His harmony is correct; the ſubjects are often new and noble; but his detail and manner of treating them are frequently dry and ſteril, and he ſpins and repeats paſſages in different keys without end. The French and Italians have a term for this tediousneſs, which is wanting in our language, they call it *roſalie*, or *roſalia;* derived from the name of a female ſaint, remarkable for repeating her "Pater noſter," and ſtringing her beads more frequently than even St. Dominic himſelf, or than any other pious perſon, that has merited a place in the Golden Legend. An Italian cries out, upon hearing a ſtring of repetitions, either a note higher, or a note lower, of the ſame paſſage or modulation, *ah ſanta Roſalia!* Indeed this ſpecies of iteration indicates a want of invention in a compoſer, as much as ſtammering and heſitation imply a want of wit or memory in a ſtory-teller. He died at Straſburgh in 1789, in the 80th year of his age.

RICIMER, count and patrician of the Weſtern empire, and an important civil and military character in the fifth century, ſerved from his youth in the Roman armies, in which he acquired great reputation by his warlike exploits, and at length came to be regarded as the ableſt commander of the age. In the reign of the emperor Avitus, being one of the chief commanders of the Barbarian troops which formed the defence of Italy, he deſtroyed, in the year 456, on the coaſt of Corſica, a fleet of Genſeric, the Vandal king, deſtined to ravage the coaſts of Gaul or Italy. His ſucceſs in this inſtance enabled him to avail himſelf of the public diſcontent to depoſe Avitus, and raiſe Majorian to the throne in the year 457. Not being raiſed to the dignity which he expected under this prince, he compelled him to abdicate the purple, which act was ſoon followed by his death. Ricimer next raiſed an obſcure man, named Libius Severus, to the throne, who bore the title of emperor during four years without performing any one imperial function. In that period, and in an interregnum of two years more, Ricimer exerted ſovereign authority, amaſſing treaſures, forming a ſeparate army, and negociating alliances. His own mean birth prevented him from aſſuming the purple, and in 467 he concurred in the inauguration of Anthemius, whoſe daughter he married. The new emperor and his ſon-in-law paſſed ſome years in union, but at length diſſentions broke out between them, which ended in the murder of the emperor, and Olybrius was proclaimed in his ſtead. Thus a third, or perhaps a fourth, emperor was added to the number of Ricimer's victims; but in a few weeks after the maſſacre of Anthemius, "Italy," ſays Gibbon "was delivered by a painful diſeaſe from the tyrant Ricimer, who bequeathed the command of his army to his nephew Gundobald, one of the princes of the Burgundians." Gibbon's Rom. Hiſt. vol. vi.

RICINA, in *Ancient Geography*, an iſland ſituated on the coaſt of Hibernia, being one of thoſe called Ebudes, according to Ptolemy and Pliny.—Alſo, a town of Italy, in the Picenum, which became a Roman colony under the reign of the emperor Severus. It was ſituated S.W. of Auximum.—Alſo, a town of Italy, in Liguria, S.E. of Genoa.

RICINOCARPODENDRON, compounded of *ricinus*, καρπὸς, *fructus*, and δένδρον, *arbor*, in *Botany*, the name of a genus of plants, eſtabliſhed by Dr. Amman, the characters of which are theſe: the flower is of the roſaceous kind, conſiſting of three petals, diſpoſed in a circular order, in the centre of which there ariſes a large and open tube, through which ſhoots up the piſtil, which grows at the bottom of the cup; this piſtil, finally, becomes a trigonal fruit, divided into three cells within, and containing each one ſeed in a rough coat.

The leaves of this tree ſometimes reſemble thoſe of the aſh, being compoſed of three or four pairs of ſmaller leaves joined to a middle rib, theſe are not ſerrated, and terminate in a ſharp point; the flowers grow at the alæ of the leaves, they are white, and are diſpoſed in lax ſpikes; the fruit is green at firſt, afterwards it becomes of a yellowiſh-red, and finally ſcarlet; it is of the bigneſs of a walnut, and in ſhape much reſembles the fruit of the ricinus; the covering of the ſeeds is black on the outſide, and red within, and each ſeed is divided into two lobes; when ripe, the fruit burſts, and the ſeeds fall out. It is a native of the Eaſt Indies. Act. Petropol. vol. iii. p. 214.

Female on the ſame plant with the male, *Cal.* Perianth inferior, of one leaf, deciduous, cloven into three, ovate, concave ſegments. *Cor.* none. *Piſt.* Germen ſuperior, ovate, covered with awl-ſhaped briſtly bodies; ſtyles three, cloven, erect and ſpreading, hiſpid; ſtigmas ſimple. *Peric.* Capſule roundiſh, three-furrowed, generally prickly all over, of three cells and three valves. *Seeds* ſolitary, nearly ovate.

Eſſ. Ch. Male, Calyx five-cleft. Corolla none. Stamens numerous. Female, Calyx three-cleft. Corolla none. Styles three, cloven. Capſule three-celled. Seed ſolitary.

Obf. Willdenow divides this genus into two fections; the firft containing fuch fpecies as have *palmate leaves*, the fecond thofe which have fimple, *undivided leaves*.

Sect. 1. *Leaves palmate.*

1. R. *communis*. Common Palma-Chrifti, or Caftor-oil Plant. Linn. Sp. Pl. 1430. Woodv. Med. Bot. 171. t. 61.—Leaves peltate; lobes lanceolate, ferrated. Stem herbaceous, pruinofe. Stigmas three, cloven at the tip.—Native of the Eaft and Weft Indies. Firft cultivated in England, as appears from Turner's Herbal, in 1562. It flowers in July and Auguft. *Root* biennial or annual, long, thick, and fibrous. *Stems* round, thick, jointed, channelled, glaucous; of a purplifh-red colour upwards. *Leaves* large, deeply divided into feven fegments, on long, tapering, purplifh ftalks. *Flowers* in long, green, and glaucous fpikes, fpringing from the divifions of the branches; the males form the lower part of the fpike, the females the upper. *Seeds* ovate, fhining, black dotted with white.

The prefent fpecies is fubject to confiderable variations. In our gardens it is a ftrong, luxuriant, fhrubby annual. In Africa it becomes a tree. Clufius obferved it in Spain, with a trunk as large as a man's body, and fifteen or twenty feet high. And Ray faw it in Sicily as big as our common Elder-trees, woody and long-lived. From the feeds of this valuable plant is extracted the *oleum ricini*, or caftor-oil, fo important for its medicinal properties as a gentle, though moft effectual, cathartic.

2. R. *viridis*. Green Palma-Chrifti. Willd. n. 2. Hort. Berol. v. 1. t. 49.—Leaves peltate; lobes oblong, toothed, the midddle one flightly three-lobed. Stem herbaceous, pruinofe. Stigmas fix.—Native of the Eaft Indies, flowering at Kew, in Auguft. Very like the laft, but always annual, with a taller and fomewhat lefs pruinofe *ftem*. *Leaves* larger, and not fo diftinctly palmate.

3. R. *africanus*. African Palma-Chrifti. Willd. n. 3. (R. communis; Desfont. Atlant. v. 2. 355.)—Leaves peltate; lobes oblong, ferrated. Stem fhrubby, fmooth.—Native of the north of Africa. *Stem* arboreous, or rather fhrubby, not pruinofe. *Leaves* fmaller than in the preceding. *Stigmas* fix, or more properly three, cloven down to the bafe.

4. R. *lividus*. Dark-leaved Palma-Chrifti. Willd. n. 4. Jacq. Ic. Rar. t. 196. Mifc. v. 2. 360.—Leaves peltate, coloured; lobes oblong, ferrated. Stem fhrubby, fmooth, coloured.—Native of the Cape of Good Hope, whence it was introduced at Kew in 1795. A *tree* ten feet or more in height. *Stem*, during the firft year, blood-red and fhining, afterwards woody and thick, afh-coloured and ftreaked. *Leaves* divided into eight or ten lobes, of a dark blood-red colour, on long, glandular ftalks. *Flowers* green. *Fruit* of a livid colour, with long, foft prickles. *Seeds* fhining, variegated with black and brown.

5. R. *inermis*. Smooth-fruited Palma-Chrifti. Willd. n. 5. Jacq. Ic. Rar. t. 195. Mifc. v. 2. 362.—Leaves peltate; lobes oblong, ferrated. Stem fhrubby, pruinofe. Capfules without prickles.—Native both of the Eaft and Weft Indies. In habit much refembling the laft, but altogether ftouter. *Stem* brown, fpotted with dark purple. *Leaves* very large, on long ftalks. *Fruit* ovate, rugofe, dark green.

6. R. *fpeciofus*. Beautiful Palma-Chrifti. Willd. n. 6. Burman. Ind. 207. t. 63. f. 2.—Leaves peltate, inclining to digitate; leaflets lanceolate, ferrated.—Native of Java. We know not that this is any where defcribed or figured, except as it occurs in the above authors.

Sect. 2. *Leaves fimple, or undivided.*

7. R. *Tanarius*. Scollop-leaved Palma-Chrfti. Linn. Sp. Pl. 1430. (Tanarius minor; Rumph. Amboin. v. 3. 190. t. 121.)—Leaves peltate, ovate, pointed, wavy, toothed.—Native of the Eaft Indies, and woods of Cochinchina. It flowers at Kew, from July to September. A middling fized *tree*, with twifted, fpreading *branches*. *Leaves* on long ftalks, fcattered, fragrant. *Flowers* in long, fimple, terminal clufters.

8. R. *dioicus*. Dioecious Palma-Chrifti. Willd. n. 8. Forft. Prodr. 67.—Leaves heart-fhaped, pointed, nearly entire. Flowers dioecious. Capfules muricated.—Native of Tanna ifland. This *fhrub* has round, fmooth, brown *branches*, the younger ones white with down. *Leaves* alternate, entire, or very obfcurely toothed; fmooth above with downy veins; refinous and dotted beneath. *Female flowers* in fmall, axillary, ftalked *clufters*. *Bractea* folitary, ovate, pointed, very large, at the bafe of every flower.

9. R. *globofus*. Globular Palma-Chrifti. Willd. n. 9. (Croton globofum; Swartz Ind. Occ. v. 2. 1181.)—Leaves ovate, obtufe, entire. Flowers dioecious. Capfules globular.—Native of lofty mountains in Jamaica. A branched, erect *fhrub*, four or five feet high. *Branches* round, ftriated, afh-coloured. *Leaves* alternate, ftalked, coriaceous. *Flowers* in terminal, fhort, erect *clufters*. *Capfule* roundifh, the fize of a pea.

10. R. *integrifolius*. Simple-leaved Palma-Chrifti. Willd. n. 10.—Leaves ovate, pointed, entire, coriaceous.—Native of the Mauritius. Adopted folely on Willdenow's authority, who defcribes it as "a *fhrub* with round, brown, fmooth, divided *branches*. *Leaves* fmooth, on channelled ftalks two or three inches long. *Clufters* axillary. *Flowers* and *Fruit* unknown. It appears to be dioecious."

Ricinus, in *Gardening*, contains plants of the tall, herbaceous, tender, annual kind, of which the fpecies cultivated is the common palma-Chrifti (R. communis).

This plant becomes a tree in its native fituation, and the feeds afford the caftor-oil of the fhops.

And there are feveral varieties of it, as the great American palma-Chrifti, which has brown ftalks that divide into two or three branches, and rife fix or feven feet high; the leaves are broader, and not fo deeply divided; they are of a deep green on both fides, and are unequally ferrate. The fpikes of flowers are fhorter, the feed-veffels rounder and of a brownifh colour, and the feeds are much lefs, and brown. This fort is a native of the Weft Indies.

Alfo the green-ftalked American palma-Chrifti, which has a thick herbaceous ftem, of a greyifh-green, with the joints not fo far afunder as in the preceeding fort: it rifes about four feet high, and is divided at the top into three or four branches, which fpread out almoft horizontally; the leaves are large, of a deep green on their upper fide, but greyifh on their under; they are deeply cut into fix or feven (fometimes eight) lanceolate fegments, which are unequally ferrate: the petioles fpread out more horizontally than thofe of the common fort, and are much fhorter: the principal ftalk and branches are terminated by loofe fpikes of flowers; the covers of the capfules are green, and clofely armed with foft fpines; the feeds are fmaller and lighter coloured than thofe of the preceding fort. This is alfo a native of the Weft Indies.

Likewife the wrinkled-capfuled palma-Chrifti, which rifes with an herbaceous ftalk about four feet high; the lower part is purplifh, and the upper deep green, the joints pretty far afunder; the leaves are of a deep green on their upper fide, but paler underneath; they are not fo deeply divided as fome of the others, and are more regularly ferrate; the fpikes of flowers are large; the males have more ftamens, with yellow anthers; the capfules are oval and wrinkled,

 but

but have no prickles; the feeds are fmall and brown. This is a native of both the Indies.

Farther, the red-ftalked palma-Chrifti, which rifes with a large reddifh ftalk to the height of ten or twelve feet, with many joints, and dividing into feveral branches; the leaves are very large, fome meafuring more than two feet and a half in diameter; are of a dark green, unequally ferrate, and not fo deeply cut as in fome of the varieties; the fpikes of flowers are large, and brown, with whitifh anthers; capfules large, oval, and clofely fet with foft prickles; the feeds are very large, and beautifully ftriped. This fort is a native of Africa and both the Indies.

And the fmall American palma-Chrifti, of which there are two fub-varieties, one with a red, the other with a pale-green ftalk, diftinguifhed in America by the names of red and white oil-feed; the ftem feldom rifes more than three feet high, fometimes dividing at the top into two or three branches; the leaves are much fmaller and more deeply divided than in the other varieties; their borders are unequally ferrate, and the fegments of the leaves are frequently cut on the fides; the fpikes of flowers are fmaller and more compact; the capfules are alfo fmaller, rounder, of a light green, and clofely fet with foft prickles; the feeds fmall, and finely ftriped. This is a native of Carolina, aud fome other places.

Laftly, the livid leaved palma-Chrifti, which is an evergreen tree, ten feet in height, and more; the trunk, during the firft year, is blood-red and very fhining; afterwards it becomes woody, as thick as the wrift, hollow with tranfverfe fepta, pithy, with circular warts at the joints from fallen ftipulas, afh-coloured, interruptedly and flightly ftreaked: before the leaves come out, they are wrapped up in red ftipulas like fheaths, that fall off foon after; the leaves are divided half way into eight, fometimes ten lobes, which are ferrate and acute, and the petiole is long; they are of a dark blood-red colour on the upper furface, and livid on the lower, with blood-red veins, the largeft lefs than a foot in diameter, quite fmooth, without any hairinefs whatever; the fruit of a livid colour, with long foft prickles; the feed fhining, variegated with black and brown. This is a native of the Eaft Indies.

Method of Culture.—All thefe forts of plants are capable of being increafed by feeds, which fhould be fown upon a hot-bed in the fpring, and when the plants are come up, be each planted into a feparate pot filled with light frefh earth, and plunged into a frefh hot-bed, watering and fhading them until they have taken root; after which they muft have a great fhare of free air when the feafon is mild, otherwife they draw up tall and weak. As the plants grow faft, and their roots in a fhort time fill the pots, they fhould be fhifted into larger pots, filled as above; and about the end of May, when the feafon is warm, be hardened to endure the open air by degrees; when, if fome of the plants be fhaken out of the pots, and planted out into a very rich border, and in dry weather duly watered, they grow to a large fize, and produce a great quantity of flowers and feeds. If it be intended to preferve any of the plants through the winter, they muft not be planted out in the full grouud, but be fhifted into larger pots occafionally, as their roots require, placing them in the open air during the fummer feafon in fome warm fituation, where they may remain until October, when they muft be removed into the green-houfe with other exotic plants, watering them fparingly in winter, and admitting free air in mild weather, as they only require to be protected from froft and cold winds.

In common, they have a fine ornamental effect in their leaves among other potted green-houfe plants, and alfo in the large open border or clumps, when cultivated as annuals; but they require room.

Ricinus *Communis*, or common Palma-Chrifti, in the *Materia Medica*. See Castor *Oil.*

RICITOSA, in *Geography*, a town of Moldavia; 20 miles W. of Birlet.

RICK, in *Rural Economy*, a term applied to a pile of corn, hay, ftraw, &c. regularly heaped up in the open air, and fheltered from wet by thatch. See Stack, and Stand, *Corn.*

Rick-*Yard*, a term fometimes given to that part of the farm-yard in which the ftacks are placed. They fhould be fufficiently large, well fheltered from winds, and perfectly fecured from all forts of vermin, efpecially rats and mice.

RICKBAD, in *Geography*, a town of Hindooftan, in Oude; 20 miles N.W. of Lucknow.

RICKETS, in *Medicine*, a difeafe affecting children, and principally characterifed by enlargement and flexure, or diftortion of the bones.

The origin and etymology of this word are equally unknown. It has occurred in this, as in feveral other inftances, that the vulgar had recognized and given a name to the difeafe, before medical men had difcriminated its nature, or at leaft had taken the pains to point out its peculiarities by any written document. The firft account of the difeafe is that of Dr. Gliffon, publifhed in the year 1650, which was the refult of fome communications on the fubject in a private medical fociety. In this treatife we are informed, that the *rickets* had firft been noticed in the counties of Dorfet and Somerfet, about thirty years before, where it was vulgarly known by this name, and that it fpread from thence over all the fouthern and weftern parts of the kingdom, but was not yet commonly known in the north. The rapidity of its progrefs, and the extent and fatality of its prevalence, are fcarcely lefs extraordinary than its general and fpeedy difappearance in later times, as no affignable caufe has ever been pointed out either for its origin or its ceffation. Its firft appearance, as a caufe of death, in the bills of mortality of London, was in the year 1634, when the total number of deaths under this head was only 14; but an extraordinary increafe foon took place. For, in 1649, the deaths from rickets amounted to 190; in 1650, to 260; in the following year, to 329; and in 1660, 521 perfons died of this difeafe. At the commencement of the 18th century, the mortality from this diforder was 393 (A. D. 1700); and it fubfequently decreafed rapidly; for in the year 1750, the number of deaths, recorded in the bills under the head of rickets, is only 21; and at the end of the century (1799), the deaths, under the head of "evil and rickets" conjoined, do not exceed 7. (See Ann. Medical Regifter, vol. i. for 1808, p. 324.) At prefent, indeed, the difeafe is almoft unknown to medical practitioners, except by name.

With the view of accommodating a claffical name both to the vulgar appellation and to the fymptoms of the difeafe, Gliffon invented the term *rachitis*, ῥαχῖτις, *i. e. fpinal* difeafe; fince the curvature of the fpine, which enfues, is one of the moft prominent fymptoms. This appellation has been adopted by the nofologifts, and all fubfequent writers, who have ufed a Latin nomenclature. (See Gliffon, de Rachitide, cap. i.) Whether the difeafe was really unknown, or did not exift, until modern times, is a queftion which it would be very unprofitable to difcufs; fince there are few fatisfactory documents to be found on the fubject. We fhall therefore proceed to deliver a hiftory of the fymptoms.

This difeafe feldom commences before the ninth month, and rarely after the fecond year, of a child's age; but it may

may appear at any interval between these two periods. Its progress is at first usually very slow. The early appearances of its approach are a flaccidity of the muscular flesh, and a certain degree of emaciation of the body, notwithstanding that the appetite for food is rather increased than impaired; together with a paleness and loss of colour in the complexion, and a slight degree of fulness, or tumefaction in the face. The head at the same time appears large with respect to the body, and the fontanelle, and even the sutures of the skull, are more open than is usual in children of the same age. The head continuing to increase in size, the forehead especially, becomes unusually prominent, and the neck appears very slender in proportion to the head. The progress of dentition is also slow, or much later than usual; and those teeth which protrude themselves soon become black, decay, and often fall out. Their ribs lose their convexity, and become flattened at their sides, while the sternum, or breast-bone, is pushed forward, so as to form a sort of ridge. At the same time, or sometimes sooner, the epiphyses at the several joints of the limbs become swelled, while the limbs between the joints appear, or perhaps actually become, more slender. The bones now are obviously every where, to a certain degree, flexible, becoming variously bent and distorted, and especially the legs and the spine of the back are incurvated in various directions. If the child had already acquired the power of walking before the commencement of the disease, it becomes daily more feeble in its motions, and more averse to exertion, and at length loses the power of walking altogether.

While these symptoms go on increasing, the abdomen always appears preternaturally full and tumid, and the stools are generally frequent and loose; yet the appetite often remains good. The faculties of the mind often exhibit a premature advancement, and the power of speech is early acquired; but in some cases the understanding is impaired, and stupidity or actual fatuity ensues. There is usually no febrile affection accompanying the disease at its commencement; but it seldom continues long before the pulse becomes frequent, and other symptoms of fever ensue.

With these symptoms the disease proceeds, and continues in some instances for several years; but, in many cases, in various stages of that progress, it ceases to advance, and the child gradually recovers its health and strength, except that the distortion of the limbs, produced by the disease, continues during the remainder of life. In other cases, however, the malady proceeds, continually increasing, until it has affected almost every function of the animal economy, by the derangement of the viscera and the impediment to their operations, which the distortion of the bones occasions. The most material danger and distress thus produced arise from the distortion of the spine, ribs, and sternum, by which the cavity of the chest is greatly diminished, and the action of the lungs and of the heart much impeded, or altogether arrested. The functions of the liver, stomach, &c. and those of the uterus and bladder, under distortions of the pelvis, are thus also often rendered morbid and distressful for the rest of life. When the head, too, is greatly enlarged, the existence of water is to be apprehended. It is unnecessary to enter into any detail of all the variety of symptoms, which are the secondary effect of these impediments to the action of particular organs; since relief is not to be obtained effectually while the mechanical impediment exists incurably, and the origin of each particular symptom will be easily explained from the circumstances of each case. The organs themselves, however, become seriously deranged under this state of pressure and obstructions; and morbid conditions have been discovered in various parts internally in the bodies of those who have died. Thus, most of the viscera of the abdomen, the liver, spleen, and mesenteric glands, have been found to be preternaturally enlarged; the lungs have been found in a morbid state, apparently from some inflammation that had come on towards the termination of the disease. The brain has been commonly found in a flaccid state, with effusions of a serous fluid into its cavities. The bones very universally have been commonly found in a flaccid state, with effusions of a serous fluid into their cavities. The bones very universally have been found to be soft, so much so indeed, as to be readily cut by a knife; and the muscular parts also soft and tender, the whole of the dead body being without that degree of rigidity which is so common in almost all others. Cullen, First Lines, par. 1724.

The great peculiarity, then, of this disease, appears to consist in a deficiency of that matter which forms the solid parts of the body, especially of the bones, or in a faulty state of the process of ossification, by which that matter is deposited in the membranes and substances destined to become bony, to give them their due firmness, hardness, and strength. There is obviously a defect in the quantity of this matter, the place of which is supplied, especially about the epiphyses of the bones, by a soft substance which increases their bulk. What this deficiency of ossific matter depends upon, it is difficult to ascertain: it may originate either in the faulty action of the organs of digestion and assimilation, by which the nutritive fluids are prevented from being properly prepared; or from a fault in the organs of secretion and nutrition, which prevents the proper elaboration of the circulating fluids. Of the nature of this latter process, however, we are totally ignorant; and practitioners have more generally referred to the former, and ascribed the disease to the actual deficiency of bony matter in the circulating fluids, as furnished by the digestive organs: yet they have been generally also compelled to refer this deficiency to some general laxity or debility of the system. But admitting the existence of such a debility, it is altogether impossible to account for its operation in diminishing the ossific matter, being limited to the early portion of childhood; for though a *mollities ossium*, or softness and flexibility of the bones, has occurred in adult life, it is a circumstance of extreme rarity. In a word, the essential nature of the disease is beyond our investigation.

Causes of Rickets.—Neither are the causes of the disease very clearly demonstrated. Great stress was laid by the earlier writers upon the *hereditary* predisposition which descended from parents to their children; but the very rapid increase of the disease among children, soon after the disorder was first noticed, and therefore the necessary primary origin of it in many whose parents must have been free from the taint, renders the opinion untenable. Indeed the rise, prevalence, and disappearance of the disease, during a certain period of time, including about a century and a half, would seem to connect its existence with some more general cause; but no one has been able to point out any peculiar physical condition of the people of England, during that period, to which such a malady can be attributed. Some have imputed it to the multiplication of manufactures and other unwholesome occupations; but the manufactures continue while the disease has nearly vanished. It is certain, however, that in later times the disease has been principally known among the children of the poor, living in close and uncleanly situations, and in dirty ill-ventilated apartments; and especially among those children who are ill-nursed, that is, in whom constant washing and proper exercise,

exercise, as well as good feeding, have not been attended to. Damp air, and residence in a cold and humid situation, have also been enumerated among the predisposing causes of rickets; and in this respect, as well as in the practice of better modes of management in infancy, the change of circumstances in the present state of great towns, and even in the habitations of the peasantry, when compared with those of the preceding century, will be deemed sufficient at least to have greatly diminished the general sources of infantile disease and mortality. See HEALTH.

Cure of Rickets.—Observation of the circumstances under which the rickets occurred, as well as of those with which it was accompanied, suggested the only means that were resorted to for the cure of this disease, until modern chemistry proposed the administration of a substitute for the deficient ossific matter; a proposal, however, which does not appear to have led to the advantages which were anticipated. The method suggested from observation of the circumstances just alluded to, was rather of a preventive than of a curative nature; and turned upon the plan of invigorating the constitution of the infant from the period of its birth. This is to be accomplished by remedies which may improve the tone of the stomach in particular, and through that medium of the system at large, or by those which operate directly upon the latter. Of these general tonic remedies, the *cold bath* seems to have been commonly found to be the most effectual, at least as a preventive of the disease. Since it became a general custom in this country, through the recommendation of medical men, to wash young childen with cold or tepid water daily, the rickets seem to have been less and less prevalent. Indeed Dr. Cullen declared long ago, that he had never met with the rickets where this practice was adopted; and that where the disease had already begun, this remedy often checked the progress of the disease, and sometimes cured it entirely.

With the same view internal medicines of a tonic quality have been generally prescribed, to remove or arrest the disease; and among these, the preparations of *iron* have been most frequently employed. A preparation of this kind was long ago recommended by Mr. Boyle, and universally adopted, under the appellation of *ens veneris*, which, notwithstanding its name, was iron. The rust of iron, and other preparations, as well as those of zinc, have been also used for the cure of rickets, in preference to the Peruvian bark, on account of the difficulty of administering this substance to infants in any useful quantity; De Haen, however, has borne testimony to the efficacy of the latter.

Much is also to be done by good nursing; that is, by a proper regulation of the exercise, diet, and clothing, by all of which the healthy performance of the functions of an infant is greatly assisted. Exercise, indeed, even in the only form in which young children can enjoy it, *viz.* that of gestation, is one of the most powerful general tonics; and even friction with dry flannels would probably contribute to the same end. The diet of children is now reduced to a much more rational standard than during the last century, and the proper mode of administering it is now too well understood to require any minute instructions in this place. (See INFANTS.) The supposition of the pernicious acidity, arising from the use of that most natural food milk, to which Zeviani and some other writers ascribed the origin of the disease, is altogether without foundation.

It is highly proper, also, where there is a ricketty tendency present, to attend to the symptoms which accompany its approach, and to correct any influence which these symptoms may have upon the general health. Above all, it is advisable to administer remedies against the derangements of the abdominal viscera, connected with tumid abdomen and irregularity of bowels, which so commonly attend that disposition. For this purpose the testaceous powders, combined with small doses of some mercurial alterative, or with rhubarb, or the latter united with steel and soda, may be prescribed with benefit. The use of emetics, which was resorted to by some practitioners, appears to be of no beneficial tendency, unless they may act on the bowels as laxatives; and a system of active purging, which was also generally employed, as it contributes to much debility, should be avoided.

It remains only to mention the chemical proposal, which M. Bonhomme of Paris proposed, of administering the component parts of bone in the way of medicine, upon the supposition that the disease depends upon the mere deficiency of these substances in the circulating blood. M. Bonhomme therefore suggested the administration of phosphate of lime and phosphate of soda in substance; and formed a powder, consisting of equal parts of these substances, of which he gave a scruple twice a day to infants. He contends that the calcareous phosphate, when taken internally, is really transmitted by the lymphatic vessels, and is applied to the purposes of ossification, and that this administration of it powerfully contributes to restore the natural proportions in the substance of the bones, and thus accelerates the cure of rickets. In support of these opinions, he relates various experiments made on young fowls, to which it was given mixed with their food, and in which, he maintains, the progress of ossification was accelerated, in comparison with others to which it was not given. (See his Memoir on Rachitis; and Duncan's Annals of Medicine for 1797.) These physiological experiments, however, lead to no legitimate deductions as to the operations of disease in the human body; and, experience in the latter has not apparently supported the doctrines of M. Bonhomme.

RICKETS is also a disease affecting sheep, as well as some sorts of vegetable crops.

RICKETY GRAIN, in *Agriculture*, a sort of vegetable disorder that often attacks wheat crops. It is, according to Dr. Anderson, a kind of disease which is totally different from that of *smut* or *rust*. The grain affected with this disease assumes a small shrivelled appearance, and irregular form; its colour is somewhat darker than good wheat of the same kind, but is different from that which is affected with either of the two other diseases. Water, when poured upon wheat of this kind, soon, he observes, moistens it, and brings to life a number of eel-shaped animals in various stages of their growth, which had taken up their residence there while the grain was yet in its succulent state, and thus occasioned the disease which produced the alteration in its form. As the grain ripens and dries, these animalcules are arrested in their progress, their life totally suspended, and their destructive operations upon the corn of course obstructed, so long as it remains in this dry state. But no sooner does this grain become soft, in consequence of being moistened with water (whether after being sown in the ground or otherwise), than these creatures are restored to life and activity; they soon begin to feed upon the grain while it is moist, and, if not interrupted in their progress by another desiccation, quickly lay their eggs (for they are oviparous), and go through the ordinary evolutions of nature. The young, when hatched in the corn that was sowed, after living upon it for some time, begin, he asserts, to eat their way up the growing stalk, and establish themselves at length in the grain itself, while it is advancing towards maturity, where they are arrested in their progress in the manner above described when it is fully ripened.

And in respect to the nature of the animalcule that produces these effects, it is remarked, that it can be preserved alive in a quiescent dried state, for twenty-eight years at least, as has been shewn by experiment, after the lapse of which period it was found to revive as readily as if its vital functions had been thus suspended only for one day. It is further stated as worthy of remark, that the eggs of this creature cannot be preserved for a length of time in a dry state, and still retain their prolificacy, neither can those among them which are very young, or those which have attained their full size, be revived after they have been dried up. It is only those individuals that are in the full vigour of life, and in a state soon to produce young, that are endowed with this singular faculty. In this case, the obvious intention of nature is to preserve the species, by keeping them in life until the grain shall be sown, and thus to have a proper food provided for their progeny, however long that may be.

RICKMAN, George William, in *Biography*, a member of the Imperial Academy of Sciences at Petersburgh, was born at Pernau in 1711, after the decease of his father, who was treasurer to the king of Sweden. Having acquired the rudiments of a good education in the gymnasium at Revel, he prosecuted his studies at the universities of Halle and Jena, but applied chiefly to mathematics and natural philosophy, to which he shewed a particular attachment. In the year 1735 he was made a member of the Imperial Academy of Sciences; in 1741 he became extraordinary professor, and in 1745 he was elected ordinary professor of experimental philosophy. He was from this period particularly attached to the new science of electricity, and applied himself particularly to atmospherical electricity. On the discoveries made in this branch of knowledge he had composed a treatise, which he intended to read on the 6th of September 1753, at a public meeting of the Academy; and in order to demonstrate what he might advance in the discourse, he made a great number of experiments on divers thunder clouds. In one of these the professor was struck dead by a flash of lightning, drawn by his apparatus into his room. Of this fatal accident there are two accounts in the Transactions of the Royal Society.

The professor had provided himself with a gnomon, an instrument to measure the strength of the electricity of the passing clouds. He was, on the 6th of August, N.S. 1753, a little before noon, at the Academy, when it thundered at a considerable distance, the sky being then clear and the sun shining bright. In the hope of confirming his former observations, or of making some new ones, he hurried home, accompanied by Solokow an engraver, that the latter might make himself master of the leading circumstances of the electrical experiments, in order to be the better enabled to represent it on a copper plate, which was to be annexed to his dissertation. The philosopher led the engraver to his apparatus, but while examining for his own use, or perhaps describing the effect of the electricity on the gnomon to his friend, with his head inclined towards it, he received a violent shock, which instantly deprived him of existence. M. Solokow observed, he said, a globe of blue fire, as big as his fist, jump from the rod of the gnomon towards the head of the professor, which was at the instant about a foot from the rod. This flash killed M. Rickman, but M. Solokow could give no account of the particular manner in which he was immediately affected by it; for, at the same time that the professor was struck, there arose a sort of steam, or vapour, which entirely benumbed him, and made him sink to the ground, so that he did not even remember to have heard the clap of thunder, which was very loud. The globe of fire was, however, attended with a report as loud as that of a pistol: a wire, which brought the electricity to his metal rod, was broken in pieces, and its fragments thrown upon M. Solokow's clothes. Upon examining the effects of the lightning in the room, it was found that the door-case was half split through, and the door torn off and thrown into the room. An attempt was made to bleed the breathless body, but no blood followed. The shoe belonging to the left foot was burst open, and uncovering the foot at that place, they found a blue mark, from which it was inferred that the electrical fluid, having entered the head, made its way out again at the foot.

Upon the body were several red and blue spots, but the hair of the head was not singed. The stocking was entire though the shoe was ripped up; the coat was uninjured though the waistcoat was much singed; and there appeared on the back of M. Solokow's coat long narrow streaks, as if red-hot wires had burnt off the nap. On opening the body the cranium was entire, and the brain perfect, but the transparent pellicles of the windpipe were excessively tender, gave way, and were easily rent. There was some extravasated blood in it, as likewise in the cavities below the lungs; those of the breast being quite sound, but those towards the back were of a brownish colour, and filled with more of the above-mentioned blood: otherwise none of the entrails were touched, but the throat, the glands, and the thin intestines, were all inflamed. After two days the body was in such a state of putrefaction that it was with difficulty got into a coffin. Phil. Trans. vol. xlix. pt. 1. Priestley on Electricity.

RICKMANSWORTH, or Rickmeresworth, in *Geography*, a small market-town in the hundred of Cashio and county of Hertford, England, occupies a low, moorish situation near the confluence of the rivers Gade and Colne, at the distance of 19 miles N.W. from London. The manor was an ancient demesne of the Saxon kings, and was given by king Offa to the abbey of St. Alban's, to which it was confirmed by succeeding monarchs, and had the charter of a weekly market and two annual fairs granted by Henry III. The church is a spacious edifice, consisting of a nave, aisles, and chancel: it was repaired in the year 1677, and again in 1802: the large gallery at the west end was probably erected about the former period. Previous to the late repairs, a large altar-tomb, in memory of Henry Cary, baron of Lepington and earl of Monmouth, stood against the south wall of the chancel; but being supposed to disfigure the place, it was removed; and a memorial slab of black marble, which was affixed to the tomb, was let into the south wall, with sculptures in white marble of the family arms. Against the north wall is a mural monument, to commemorate sir Thomas Fotherly (gentleman of the privy chamber to Charles I.), and his son and grandson. Several others of the family are recorded on a slab on the floor. In the east part of the south aisle are three large altar-tombs, in which are deposited the remains of the families of Colte, Salter, and Whitfield, inhabitants of this town. In the north aisle a neat mural monument records the memory of Timothy Earle, esq. of Moor-house, who died in May 1787, aged 80; and also of Dorothy his wife. A marble tablet against the north wall commemorates admiral William Bladwell, formerly of Money-hill in this parish, who died in March 1783, at the age of 80.

Rickmansworth, by the vicinity of several streams, is rendered very convenient for trades that require the assistance of water: several mills have consequently been erected for various purposes in its neighbourhood: a large cotton and flour-mill at the south entrance to the town; one for flock

and

and filk at a fmall diftance to the weft; and feveral for paper, &c. towards the north, on the rivulet that flows from Chefham. Additional employment, particularly for females, is derived from the manufacture of ftraw-plat. The market was formerly diftinguifhed for its corn trade, but is now little frequented, though toll free: the market-houfe is a mean wooden ftructure, raifed on pillars, and open beneath. The population, as afcertained under the act of 1811, was 3230, the number of houfes 589.

The manor of the *Moor* in Rickmanfworth parifh, being anciently parcel of the poffeffions of St. Alban's abbey, was, about the year 1431, with other contiguous manors, held under that foundation by a tenant named Flete, who had for feveral years refufed either to pay the quit-rent, or to perform the covenanted fervices claimed by the abbot; one of which was finding for his ufe, and that of his fucceffors, "one nag-horfe to carry him to Tynemouth, whenever he or they fhould vifit that cell:" the difpute was at length decided in favour of the abbot by fir William Babyngton, chief juftice of the common pleas; and Flete was compelled to the obfervance of the accuftomed homage and fealty. The next poffeffor on record was Ralph de Boteler, lord of Sudely in Gloucefterfhire. It is now held by Robert Williams, efq. banker of London.

Moor-Park houfe, the fplendid refidence of this gentleman, is a magnificent building of the Corinthian order, ftanding in a finely wooded park about five miles in circumference, and having two fronts, refpectively facing towards the north and fouth. The height of the ground to the fouth contracts the view; but the northern front commands an extenfive profpect; the hill, which had previoufly obftructed the fight, having been lowered about the year 1725, at the expence of 5000*l.* This was effected by B. H. Styles, efq. to whom the prefent manfion is indebted for its chief grandeur, as he new cafed and fronted it with Portland ftone; and having built the magnificent portico, erected two wings for the chapel and offices, and connected them with the centre by colonnades of the Tufcan order. The charge of the carriage of the ftone from London, amounted to upwards of 15,000*l.*, and the entire expence, including the improvements in the park, was more than 150,000*l.* Beauties of England and Wales, vol. vii. by E. W. Brayley.

RICKSGÖLD, in *Commerce*, one of the two fpecies of paper currency in Sweden, the other being *banco*. The latter is iffued by the national bank, and the former by the Rickfgöld bank, which is under the direction of government. Banco is 50 *per cent.* better than Rickfgöld; that is, two dollars of the former are worth three dollars of the latter. Banco is a legal tender, and has lately been declared, by royal authority, the national currency. Rickfgöld is current in all payments; but as no frefh iffues of this paper have been lately made by government, it is continually decreafing in circulation, while banco increafes. Both currencies are made payable to bearer on demand, and are accordingly difcharged when prefented for payment.

RICLA, in *Geography*, a town of Spain, in Aragon, on the Xiloca, anciently called "Nertobriga;" 14 miles N.E. of Calatayud.

RICOCHET Battery, in *Fortification*. See Battery *à Ricochet*.

Ricochet *Firing*, in the *Military Art*, is a method of firing with pieces elevated from three to fix degrees, and loaded with a fmall charge, fo that the ball may bound and roll along the infide of the parapet. The ball or fhot, thus difcharged, goes rolling and bounding, killing, maiming, or deftroying all it meets with in its courfe, and creates much greater diforder, by moving thus flowly, than if thrown from the piece, whofe elevation is greater, with greater violence.

The word *ricoche* fignifies *duck and drake*, terms applied to the bounding of a flat ftone thrown almoft horizontally into the water.

RICOTE, in *Geography*, a town of Spain, in the province of Murcia; 20 miles N.W. of Murcia.

RICOTIA, in *Botany*, a Linnæan name whofe origin no one has been able to explain, nor can we throw any light upon it. It has the appearance of a proper name, and was probably given in honour of fome obfcure botanift.—Linn. Gen. 337. Schreb. 440. Willd. Sp. Pl. v. 3. 477. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 4. 98. Juff. 239. Lamarck Dict. v. 6. 210. Illuftr. t. 561. Gærtn. t. 142. —Clafs and order, *Tetradynamia Siliquofa*. (*Siliculofa*; Brown.) Nat. Ord. *Siliquofæ*, Linn. *Cruciferæ*, Juff.

Gen. Ch. *Cal.* Perianth inferior, deciduous, of four, oblong leaves, approximating in a parallel manner. *Cor.* cruciform, of four, obcordate petals, fpreading. *Stam.* Filaments fix; four the length of the tube; two fomewhat fhorter: anthers oblong, acute. *Pift.* Germen fuperior, cylindrical, the length of the ftamens; ftyle fcarcely any; ftigma acute. *Peric.* Pod feffile, lanceolate-oval, with one or two cells, and two flat valves. *Seeds* moftly four, orbiculate, compreffed.

Eff. Ch. Pod of one cell, oblong, compreffed: valves flat.

1. R. *ægyptiaca*. Egyptian Ricotia. Linn. Sp. Pl. 912. (Lunaria foliis fupradecompofitis: foliolis trifidis, filiquis oblongis pendulis; Mill. Ic. v. 2. 113. t. 169.)—Native of Egypt, flowering in June and July.—*Root* annual. *Stem* a foot high, fmooth and branching. *Leaves* unequally pinnate; leaflets various, fome undivided, others three-lobed, of a lucid green. *Flowers* purple, on long ftalks, at the fides and ends of the branches, in fmall, loofe *clufters*. *Pods* drooping, when ripe of a pale brown colour.

This genus is very nearly allied to *Lunaria*, from which indeed it chiefly differs in having a feffile, not ftalked, pod.

RICZIWOL, in *Geography*, a town of the duchy of Warfaw; 30 miles N. of Pofen.

RIDA, a town of the Valais; 4 miles S.E. of Sion.—Alfo, a town of Sweden, in the province of Upland; 24 miles N.E. of Stockholm.

RIDALE, or Risdale, a river of England, in the county of York, which runs into the Swale, near Richmond.

RIDAL-HEAD, a mountain of England, in Cumberland; 2 miles N. of Amblefide.

RIDDERHUDE, a town of the duchy of Bremen; 8 miles N. of Bremen.

RIDDLE. See Ænigma.

Riddle, in *Rural Economy*, a fort of fieve ufed to feparate duft and the feeds of plants from corn. They are made of different forms and fizes, for different ufes.

RIDE of hazle, or other wood, is a group or clufter of fprigs fhooting out of the fame root or ftock.

Ride, or *Riding*, in the *Manege*. To ride fignifies to learn to ride. Thus, he rides under a good mafter. For an account of the origin and hiftory of the art of riding, we refer to the article Horse.

In addition to the obfervations which occur under that article, in proof of the antiquity of the art of riding, we fhall here introduce fome other confiderations, which tend to evince the priority of riding to the ufe of chariots. Egypt appears to have been the fpot in which the horfe feems to have been firft fubdued and difciplined by man;

and it is evident from the Mofaic hiftory, that in the firft inftance where mention is made of Pharaoh's chariots, he is likewife faid to have had his horfeman: which word, in the Hebrew language, is explained by the commentators to mean one who fits upon and guides a horfe. Befides, the Hebrew word, "parafh," horfeman, is derived, as Buxtorf fays, from a Hebrew root, which fignifies to *prick* or *fpur*; and the rider, or fpurrer, was fo denominated, becaufe he ufed to prick or fpur the horfe. Aben-Ezra fays, that the horfeman was fo called from wearing fpurs on his heels. By this account and explanation of the word, which in the Hebrew fignifies a "horfeman," we are informed of the great antiquity of fpurs; and may reafonably conclude, that the art of riding was not only known, but, from the invention of fpurs, had alfo received an improvement, not unworthy of the difcovery of more difcerning times; and feems to imply, that riding was not only familiar, but even advanced in thofe primitive times to a degree of exactnefs, perhaps, not hitherto fufpected. The arguments here, and alfo under the article Horse, alleged in proof of the feniority of horfemanfhip to that of the ufe of chariots, may be ftrengthened by the following paffage in the book of Job, where, fpeaking of the oftrich, he fays, "fhe lifteth herfelf on high, fhe fcorneth the horfe and its rider;" which expreffion feems to imply that it was a cuftom, as it is now in fome nations, to hunt this bird on horfeback, and that fhe was fuperior to the fwifteft horfe. Hence it muft be granted that riding was practifed in his country, and at the time in which he lived; nor is it to be forgotten, that he lived in a country diftinguifhed above others for its horfes, and in which no chariot was ever known to have been ufed. We may alfo add to the fame purpofe, the noble defcription which he gives of the horfe, fo known and fo admired, in which he fpeaks of him only as being rode, and not driven in a carriage: and if this writer, as fome learned perfons have thought, lived long before the time of Mofes, what he fays in relation to this fubject muft be anterior to the Mofaic hiftory; and if that be the cafe, the antiquity of equitation will be carried fo high, as to put it beyond the reach of inquiry and inveftigation. In the defcription juft referred to, the Englifh tranflators make Job fay, "that this animal's neck is clothed with *thunder*;" an expreffion no lefs falfe than abfurd. The true rendering of this paffage is, that his neck is clothed with a *mane*. Thus Bochart, Le Clerc, Patrick, and other commentators tranflate it. Bochart fays, that the word, which in Hebrew fignifies *thunder*, is fynonimous with that for the *mane* of the horfe; but this being the cafe, it is aftonifhing that the tranflator fhould have fet afide the juft and natural fignification, and have chofen to cover the horfe's neck with *thunder*, inftead of a *mane*; nor is it lefs amazing, that this nonfenfe fhould have been extolled by the author of the "Guardian," and others, as an inftance of the fublime. We fhall here obferve, that the Grecians, in many inftances, chofe mares for riding before horfes. Ælian fays, they thought them fitter for the courfe; and Virgil only names the mares of Epirus, as running in the Olympian race. Pliny fays, they were fwifter than horfes. Berenger's Hift. and Art of Horfemanfhip, vol. i. p. 12, &c.

The knowledge and utility of the art of riding confift in being able to difcern, and dextrous to employ, the means by which the horfe may be brought to execute what the rider requires of him, with propriety, readinefs, and fafety: and this knowledge in the man, and obedience in the horfe, fhould be fo intimately connected, as to form one perfect whole; this union being fo indifpenfably neceffary, that, where it is not, there is no meaning between the man and horfe: they talk different languages, and all is confufion.

The Greeks, who excelled in the art of riding, were accuftomed to mount and difmount, by vaulting and leaping from and upon the backs of their horfes, as well as from one horfe to another. Thefe feats of activity feem to have been firft practifed in battle, and in thofe ages when faddles, and confequently ftirrups, were unknown. The utility of this method muft be acknowledged; for if one horfe was tired, wounded, or killed, his mafter had another for his fervice; two or three being led into the field, which were ufed as occafion required. Thefe exercifes, fo effentially neceffary in war, were, after a time, performed in the public games, and other occafional exhibitions, merely to fhew the nimblenefs and addrefs of the horfeman; and the modern art of vaulting, in all its variety of poftures and methods, and which has *now* little more in view than to difplay the activity of the performer, is, without doubt, derived from this ancient practice; as well as the whole modern manege, except fome few experiments, calculated merely for grace and pleafure, is borrowed from the different motions and evolutions performed by men and horfes in battle. To this likewife we owe the folemnities and fports of tilts, tournaments, and jufts; invented as a mock-war, to fill up the lazy hours of peace, to infpire and keep alive a martial fpirit, and to render the body active, robuft, and expert in the feats of arms.

It is well known that the Romans were indebted to Greece for many arts and ufeful improvements, and particularly horfemanfhip, which was received and adopted by them with fuch eagernefs, and cultivated with fuch diligence and zeal, that they foon were able to excel their mafters. Romulus, at a very early period, inftituted his order of "equites," or horfemen, as Athens and Sparta had done before, on purpofe to encourage the practice of riding, and engage his new fubjects to keep horfes at their own expence, which, in thofe times, were fo coftly, that the rich alone were equal to the charge of maintaining them. Among the Romans they had a horfe called "fingularis," or fingle, upon which a man rode without a faddle, ufing only a cloth, like the Greeks, faftened with a furcingle, or elfe fitting upon the bare back. The riders were alfo, occafionally, tied and bound to their horfes by thefe girths, that they might fit more firmly and fecurely; but the practice was imprudent and dangerous, as they were thus liable to be dragged and torn by the horfe, in cafe they were unfeated, like the warrior defcribed by Silius Italicus (lib. 4. Punic.):

"——— Rapiturque pavore
Tractus equi, vinctis connexa ad cingula membris."

Lock faddles, now but little ufed, are liable to the fame objection.

The art of riding fubfifts in various modes and different degrees of fkill and perfection among different nations. In Arabia, where the horfes are the fineft and beft of their kind, their owners manage them with fingular dexterity. Their faddles have the back part, or "cantle," fo high, that it reaches more than half-way up the rider's back. The ftirrups are flat, in the Turkifh manner, and contain the whole foot. They never ufe a girth, which makes it more difficult to mount and keep their feat. The Arabian youth underftand the equilibre, and keep their body in a juft counterpoife; being fo dextrous, that they will ftand on the faddle, while the horfe runs at full fpeed, fling their lances, turn round, throw themfelves over, and ftand upon their heads; the horfe continuing his career all the time.

Similar evolutions were practised by the ancient Romans. The Turks ride with their ftirrups fo fhort, that their knees are almoft as much bent, as when they fit upon their hams upon a fofa. Their faddles are as large and unwieldy as a pack-faddle: they faften and fecure them upon the horfe by a large girth, which paffes over them, and prevents the faddles from turning, which their great weight would otherwife make them do. The bridles are generally gilt and ornamented, but otherwife very clumfy and ill-made. The Turks feldom ufe fpurs, or carry a whip or fwitch; and yet they have an abfolute command over their horfes, and make them do whatever they pleafe. In riding, they ufe only a ftick, about three feet in length, and of the fize of a large cane. This they hold by the middle, and ftrike the horfe with it on his neck with either end, to direct and compel him to turn; making them run at full fpeed, and laying them out fo rapidly, as almoft to make their bellies touch the ground; the riders, at the fame time, ftriking their darts into a turban, or toffing them in the air, riding after, and catching them before they fall to the ground. Others, efpecially the Arabs belonging to the fultan, will leap from one horfe to another, running at their utmoft fpeed. Others will creep under the belly, and up to the faddle again; others will turn two or three times round the horfe's neck, and others will ftand upright upon the faddle, and turn their faces to the tail, the horfes all the time going at their utmoft ftretch.

The Perfians have great perfonal addrefs and activity on horfeback. They play at "Mall" mounted on their horfes, and ftrike the ball with certainty and furprifing fkill. They place alfo upon the top of a tree, or high pole, an apple, as a mark to fhoot at with arrows. They fet off at full fpeed, and when they are got beyond the mark, turn themfelves round towards the croupe, draw their bows, and in this pace, and this attitude, feldom fail to hit the apple. The Tartars have, in all ages, been famous, under different names, for their love of horfes, whofe flefh they eat, drinking the milk of the mares, and fkill in riding. It is a practice with them to tie the reins of their bridles to their girdles, and by the motion of their bodies alone to govern and direct their horfes; pulling them into different attitudes, and making them perform a variety of evolutions. By this method they have their hands at liberty for the ufe of their weapons, which they manage with a fkill furpaffing that of other nations. Some will hold their bows in the fame hand in which they hold their bridles, and at the fame time draw the bow, and guide their horfe with great addrefs, always riding with their ftirrups very fhort, in order to collect themfelves better, and be able to rife up, as it were, when they are going to attack an enemy, and ftrike a blow.

The venerable Bede fays, that the Englifh began to ufe faddle-horfes about the year 631, when prelates and others rode on horfeback, who till that time were accuftomed to go on foot; but that if, upon urgent occafions, they were obliged to ride, they ufed mares only, in token of their humility; the mare not being fo full of pride or fpirit as the horfe. In the reign of Edward III. the horfes called "Dextrarii," correfponding to thofe that are now termed *managed* horfes, or horfes *dreffed* and difciplined for war, were held in the higheft eftimation, and appropriated to military exercifes; and upon common occafions, perfons of rank and confideration always rode upon horfes of inferior degree, diftinguifhed by the names of "Courfers, Amblers, Palfreys, Hackneys, Nags, and Poneys," recommended by their eafy paces and quiet temper. In feveral countries it was a cuftom, rigoroufly obferved, that no knight of chivalry, or other gentleman, fhould ride upon a mare, it being thought difhonourable and vile. The mares were always devoted to the cart, and all the ignoble fervices. The Spaniards, Turks, and fome other nations, ftill adhere to this abfurd notion, upon all occafions. The Dextrarii above-mentioned were called "magni equi," or great horfes, being of the largeft fize, and intended to ferve in war or for the exercife of the tournament; and as thefe great horfes were required to be *dreffed* or taught, that they might perform their tafks with readinefs and fidelity; and as it is neceffary that the rider fhould have knowledge and fkill to guide his horfe, thofe perfons who profeffed the fcience of arms were obliged to learn the art of managing their horfes, in conformity to certain rules and principles; and hence came the expreffion of learning to "ride the great horfe."

After an ample review of the ftate of horfes in England, Berenger takes occafion to diftribute them into two general claffes, which may be arranged under two diftinct periods of time. In the firft era, as it was an univerfal cuftom for horfemen to fight in armour, the burden was fo heavy, and the fervice fo fevere, that none but *large* and *ftout* horfes were equal to the tafk. The practice of raifing fuch a breed of horfes began about the time of Henry II., or fomewhat earlier, and continued till towards the end of the reign of Elizabeth. About the reign of James, armour, being rendered ufelefs by the invention of fire-arms, was laid afide; and the *great* horfe became ufelefs, and, on many occafions, even improper. *Lighter* and more *nimble* horfes were therefore brought into ufe, and here begins the era which comprehends the fecond clafs of horfes, called the *light* or *fwift* breed. This ingenious writer clofes his review with obferving, that, however highly gifted the horfes may be, there are *duties* incumbent alfo upon thofe who are to ride them, without an attention to which all the talents of the horfe, inftead of being called forth and improved, will be crufhed, extinguifhed, and nature have been kind in vain. Thefe duties are comprehended under the "art of riding." This art has been, as this author regrets, fo long neglected and defpifed, that one would be almoft prompted to conclude that a fatality had conftantly attended it in this country; favoured as it is with every advantage for breeding, nourifhing, and procuring the fineft horfes of all forts, and with a nobility and gentry, whofe love of exercife, activity, courage, perfonal endowments, and commanding fortunes, would qualify them to take the lead, and "witch the world with noble horfemanfhip;" yet, with all thefe high privileges, they have fuffered it to languifh, and almoft perifh in their hands; for a length of time it has been able to boaft but of a very few perfons who have ftood forth as its avowed friends and protectors. The duke of Newcaftle honoured it with his practice, and greatly enriched it with his knowledge. Sir Sidney Medows, fir William Hope, and the earl of Pembroke, are alfo mentioned with approbation and refpect. Our author adds, that fince the acceffion of his prefent majefty, the profpect has brightened, and better times begin to dawn. Since this happy event, the art has manifefted figns of recovery; public riding houfes have been opened, encouraged, and frequented; and the art has been fo far protected and honoured by his majefty, that, as our author fays, we may expect to fee the golden age of horfemanfhip revive, and that men will no longer "complain of the want of excellent horfes, nor the horfes *groan* for want of worthy riders." This art has been much indebted to the publication of "The Hiftory and Art of Horfemanfhip," by Richard Berenger, efq., which has furnifhed various extracts, to be found under their appropriate titles, in our Cyclopædia. We fhall here fubjoin fome particulars that

that have not elsewhere been introduced, and close the article with suitable references for the direction of the reader.

The posture of the body is an object of primary consideration in the art of riding. In reference to this object, the body may be divided into three parts, two of which are moveable, and the other immoveable. Of the two moveable parts, the first is the trunk or body, down to the waist; the second is from the knees to the feet; and the remaining immoveable part is that between the waist and the knees. The parts which ought to be without motion are the fork or twist of the horseman, and his thighs; and for this purpose, they ought to have a certain hold or centre upon which to rest, so that no motion of the horse may disturb or loosen them; this point or centre is the basis of the hold which the horseman has upon his horse, and is called the "seat;" and hence it must appear, that not only the grace, but the symmetry and true proportion of the whole attitude depends upon those parts of the body that are immoveable. Let the horseman then place himself at once upon his twist, sitting exactly in the middle of the saddle; let him support this posture in which the twist alone seems to sustain the weight of the whole body, by moderately leaning upon his buttock; let his thighs be turned inward, and rest flat upon the sides of the saddle; and in order to this, let the turn of the thighs proceed directly from the hips, and let him employ no force or strength to keep himself on the saddle, but trust to the weight of his body and thighs: this is the exact equilibre: in this consists the firmness of the whole building, a firmness which young beginners are never sensible of at first, but which is to be acquired, and will always be attained, by exercise and practice. A moderate stress upon the buttocks is necessary, because a person that sits full upon them can never turn his thighs flat upon the saddle; and the thighs should always lie flat, because the fleshy part of the thigh, being insensible, the horseman would not otherwise be able to feel the motions of his horse; the turn of the thigh should be from the hip, because this turn can never be natural; but as it proceeds from the hollow of the hip-bone, the horseman never avails himself of the strength or help of his thighs, because, besides their being then less steady, the closer he pressed them to the saddle, the more would he be lifted above the saddle; and with respect to his buttock and thighs, he ought always to be in the middle of the saddle, and sit down full and close upon it. With regard to the position of the body or trunk, which is the first of the moveable parts, and which comprehends the head, the shoulders, the breast, the arms, the hands, the reins, and the waist of the horseman, we shall begin with the head. This should be free, firm, and easy, and thus prepared for all the natural motions which the horseman may make in turning it to one side or the other. The shoulders only influence, by their motions, that of the breast, the reins, and the waist. The horseman should present or advance his breast, by which his whole figure is opened and displayed; he should have a small hollow in his reins, and push his waist forwards to the pommel of the saddle, because this position corresponds, and unites him to all the motions of the horse. The mere throwing of the shoulders back produces all these effects in the degree that is requisite; whereas if we were to look for the particular position of each part separately, and by itself, without examining the connection subsisting between the motions of one part with those of another, there would be such a bending in the reins, that the horseman would be hollow-backed; and by forcing his breast forward and his waist towards the pommel of the saddle, he would be flung back, and must sit upon the rump of the horse. The arms should be bent at the elbows, and the elbows should rest equally upon the hips. It is indeed the bridle-hand which ought to be steady and immoveable, and hence it might be concluded, that the left elbow only ought to rest upon the hip; but grace consists in the exact proportion and symmetry of all the parts of the body; and having the arm on one side raised and advanced, and the other kept down and close to the body, would present an aukward and disagreeable appearance. It is this which determines the situation of the hand which holds the whip, the left hand being of an equal height with the elbow; so that the knuckle of the little finger and the tip of the elbow be both in a line; this hand then being rounded neither too much nor too little, but so that the wrist may direct all its motions, the right hand, or the whip-hand, should be placed lower and more forward than the bridle hand. It should be lower than the other hand, because if it were on a level with it, it would restrain or obstruct its motions, and if it were higher, it could not take so great a compass as the bridle-hand, which must be always kept over-against the horseman's body; it is absolutely necessary to keep the proportion of the elbows, that it should be lower than the other. The second division of the moveable parts includes the legs and feet. The legs serve for two purposes; they may be used as aids or corrections to the animal; they should therefore be kept near the sides of the horse, and in a line with the rider's body; for being near that part of the horse's body where his feeling is most delicate, they are ready to perform their office at the moment when they are wanted. Besides, as they are an appendage to the thighs, if the thigh is upon its flat in the saddle, they will necessarily be turned just as they ought, and will infallibly give the same turn to the feet, because the feet depend upon them, as they depend upon the thighs. The toe should be held a little higher than the heel, for the lower the toe is, the nearer will the heel be to the sides of the horse, and must be in danger of touching his flank. Many persons, however, when they raise their toe, bend and twist their ankle, as if they were lame in that part. The reason is plain; it is because they make use of the muscles in their legs and thighs, whereas they should employ only the joint of the foot for this purpose; a joint given by nature to facilitate all the motions of the foot, and to enable it to turn to the right or left, upwards or downwards. Such, according to Mr. Berenger, is the mechanical disposition of all the parts of the horseman's body.

The hand, in horsemanship, admits of five different positions, in order to guide and govern the motions of a horse. The first is that general position from which proceed, and indeed ought to proceed, the other four.

Hold your hand three fingers breadth from your body, as high as your elbow, in such a manner that the joint of your little finger be upon a right line with the tip of the elbow; let your wrist be sufficiently rounded, so that your knuckles may be kept directly above the neck of your horse; let your nails be exactly opposite your body, the little finger nearer to it than the others, your thumb quite flat upon the reins, which you must separate by putting your little finger between them, the right rein lying upon it: this is the first and general position.

Does your horse go forwards, or, rather, would you have him go forwards? Yield to him your hand, and, for that purpose turn your nails downwards, in such a manner as to bring your thumb near your body; remove your little finger from it, and bring it into the place where your knuckles were in the first position, keeping your nails directly above your horse's neck: this is the second.

 Would

Would you make your horse go backwards? quit the first position; let your wrist be quite round; let your thumb be in the place of the little finger in the second position, and the little finger in that of the thumb; turn your nails quite upwards, and towards your face, and your knuckles will be towards your horse's neck. This is the third.

Would you turn your horse to the right? leave the first position, carry your nails to the right, turning your hand upside down, in such a manner, that your thumb be carried out to the left, and the little fingers brought in to the right. This is the fourth position.

Lastly, would you turn to the left? quit again the first position; carry the back of your hand a little to the left, so that the knuckles come under a little, that your thumb may incline to the right, and the little finger to the left. This makes the fifth position.

These different positions, however, alone are not sufficient; we must be able to pass from one to another with readiness and order.

Three qualities are essentially necessary to the hand. It ought to be firm, gentle, and light. We call that a firm or steady hand, whose feeling corresponds exactly with the feeling in the horse's mouth, and which consists in a certain degree of steadiness, constituting that just correspondence between the hand and the horse's mouth, which every horseman wishes to find.

An easy or gentle hand is that which, by relaxing a little of its strength and firmness, eases and mitigates the degree of feeling between the hand and horse's mouth, which we have already described.

Lastly, a light hand is that which lessens still more the feeling between the rider's hand and the horse's mouth, which was before moderated by the gentle hand.

The hand, therefore, with respect to these properties, must operate in part, and within certain degrees, and depends upon being more or less felt or yielded to the horse, or withheld.

It should be a rule with every horseman not to pass, at once, from one extreme to another, from a firm hand to a slack one; so that in the motions of the hand you must, upon no account, jump over that degree of sensation which constitutes the easy or gentle hand. Were you at once to go from a firm hand to a slack one, you would then entirely abandon your horse, you would surprise him, deprive him of the support he trusted to, and precipitate him on his shoulders, supposing you do this at an improper time. On the contrary, were you to pass from the slack to the tight rein, all at once, you must jerk your hand, and give a violent shock to the horse's mouth; which rough and irregular motions would be sufficient to falsify the firmest appui, and ruin a good mouth.

It is indispensably necessary, therefore, that all its operations should be gentle and light; and, in order to this, it is necessary that the wrist alone should direct and govern all its motions, by turning and steering it, if we may so say, through every motion that it is to make.

In consequence, then, of these principles, we insist that the wrist be kept so round that your knuckles may be always directly above the horse's neck, and that your thumb be always kept flat upon the reins. In reality, were your wrist to be more or less rounded than in the degree we have fixed, you could never work with your hand but by the means of your arm; and, besides, it would appear as if it were lame; again, were your thumb not to be upon the flat of the reins, they would continually slip through the hand, and by being lengthened, would spoil the appui; and, in order to recover them, you would be obliged every moment to raise your hand and arm, which would throw you into disorder, and make you lose that justness and order without which no horse will be obedient, and work with readiness and pleasure.

Those motions, which are called descents of the hand, are made three different ways, either by dropping the knuckles directly, and at once, upon the horse's neck, or by taking the reins in the right hand, about four fingers' breadth above the left, and letting them slide through the left, dropping your right hand at the same time upon the horse's neck, or else by putting the horse under the button, as it is called; that is, by taking the end of the reins in your right hand, quitting them entirely with your left hand, and letting the end of them fall upon your horse's neck. These motions, however, which give a prodigious grace to the horseman, never should be made but with great caution, and exactly at the time when the horse is quite *together*, and in the hand; and you must take care in counterbalancing, by throwing back your body, the weight of the horse upon his haunches.

The appui being always in the same degree, would heat the mouth, would dull the sense of feeling, would deaden the horse's bars, and render them insensible and callous; this shews the necessity of continually yielding and drawing back the hand, to keep the horse's mouth fresh and awake. See Appui.

The effects produced by the several positions and motions of the hand above described, are as follow: the hand directs the reins, the reins operate upon the branches of the bit; the branches upon the mouth-piece, and the curb; the mouth-pieces operate upon the bars, and the curb upon the chin of the horse.

The right rein guides the horse to the left, the left rein to the right. Would you go to the right? you pass to the fourth position of the hand, that is, you carry and turn your nails to the right; now, in carrying thus your nails to the right, and reversing your hand in such a manner that your thumb points to the left, and your little finger being raised turns to the right; you, by this means, shorten your left rein; it is this left, therefore, that turns and guides the horse to the right. Would you go to the left? pass to the fifth position; you will carry the back of your hand to the left, so that your nails will be turned downward a little, your thumb will be to the right, the little finger to the left; this will shorten the right rein; the right rein, therefore, determines your horse to the left.

We have already said, that the effect which the mouth-piece has upon the bars, and of the curb upon the chin, depends upon the branches of the bitt: when the branches rise, or are turned upwards, the mouth-piece sinks; and when the branches sink, the mouth-piece rises; so that when your horse is going straight forward, if you keep your hand low, and close to your body, the mouth-piece then presses stronger upon the bars; and the chain or curb having, in consequence, more liberty, acts less upon the beard. On the contrary, if you keep your hand high, a little forward, and consequently a little out of the line of the end of the branches, the mouth-piece then sinks, and the branches, of necessity, operate upon the curb, which presses then very strongly upon the beard. Now, in order to place, and bring in your horse's head, you must hold your hand low; and, in order to raise and lighten a horse that weighs upon the hand, and carries his head too low, you must advance your hand a little, and keep it high.

Would you have your horse go back, come to the third position? but take care to round your wrist exactly, in order to work equally with both your reins; and by this means aid your horse more effectually to go back straight and balanced

lanced between your legs, which he could never do, if one rein were to operate ſtronger than the other.

There are particular caſes where the reins are ſeparated, and one held in each hand; it is uſual to ſeparate them, when you trot a young horſe, or when you are to work one who is diſobedient and reſiſts his rider; upon theſe occaſions, keep both your hands upon a level, low, and near your body. To turn to the right, uſe your right rein; to go to the left, uſe your left rein; but in order to make them have their effect, move your arm gently, turning it a little from your body, keeping your hand always low, and even near your boot.

Every horſeman, who would be perfect in his art, ought to know the diſpoſition of his horſe, the vices to which he is ſubject, the cauſes from which they proceed, and the proper method of reſtraining or amending them. Sometimes a horſe will rebel, when you preſs him to do ſomething of which he is ignorant; in this caſe he ſhould be taught what you expect. If he knows, but cannot, through inability, perform what you require, endeavour to aſſiſt nature by the help of art; but if he knows, and is able to do what you expect, firſt try every method which patience and perſeverance can ſuggeſt, and if you fail, compel him by force and ſeverity. A horſe may be imperfect and bad from four cauſes: weakneſs, heavineſs in his make, want of courage, and ſloth; and four qualities muſt conſpire to make a good horſe, *viz.* ſtrength, activity, courage, and judgment. By a combination or mixture of theſe different qualities, are the various diſpoſitions of horſes produced; and the remedy ought to be adapted to the nature of the animals as well as to the diſorder which the horſeman propoſes to rectify. A horſe may be difficult to be mounted; examine the ſource of this vice. It may be owing either to the ignorance, or the brutality, of thoſe who have firſt had to do with him, or perhaps that the ſaddle may have hurt him, or elſe to a temper naturally bad. To whatever cauſe it may be owing, remember never to beat him; for inſtead of curing him, you would certainly confirm him in his vice; clap him gently when you approach him, ſtroke his head and mane, talk to him, and as you talk, clap the ſeat of the ſaddle; keep yourſelf ſtill all the while, put your foot only in the ſtirrup to encourage your horſe, without doing any more, in order to make him familiar, and to loſe all apprehenſion and fear when he is going to be mounted; by little, and by degrees, at laſt, he will let you mount him; you will immediately get down, and remount, and ſo ſucceſſively for ſeveral times together, without attempting to do any thing elſe; but ſend him back to the ſtable. If it happens that when you are upon him, he runs from the place where you got upon him, bring him to it immediately, keep him there ſome time, coax him, and ſend him away. The firſt leſſons ought to be well weighed, when you undertake to bring a young horſe to obedience, and to reclaim him from liberty to the ſubjection of the bridle, ſaddle, and the weight of his rider; ſo reſtrained, it is not ſurpriſing if he ſhould employ all his ſtrength againſt you in his own defence.

The generality of colts are difficult to be turned and guided as you would have them go; we ought not, however, to be ſurpriſed at this their firſt diſobedience. It muſt be imputed to the habit they acquire from their birth, of conſtantly following their dams; indulged in this liberty, and ſubjected all at once by the bit, it is but natural they ſhould rebel. There is no way of eradicating theſe firſt impreſſions, but by gentleneſs and patience. A horſeman who ſhould make uſe of force and correction, and employ it all at once upon a young horſe, would diſcourage and make him be vicious ever after. If, therefore, your horſe refuſes to go forward, you muſt lead another horſe before him; the perſon who rides the colt will try from time to time, and, inſenſibly, to make the colt go abreaſt with him, and afterwards get before him. If, being ſurpriſed at ſeeing the horſe no longer, he ſtops, or runs back, the rider muſt endeavour to drive him forward either by his voice, or ſome kind of ſlight inſtrument, or he that rides the other horſe may give him a ſtroke with the chambriere, in order to make him go forward; if theſe methods ſhould not ſucceed, he will go before him again with the other horſe; by degrees (for one leſſon will not be ſufficient) the colt will grow accuſtomed to it, and, at laſt, will go on of himſelf.

Moſt horſes who ſtart have ſome defect in their ſight, which makes them fear to approach the object. The horſeman, upon theſe occaſions, inſtead of having recourſe to puniſhment, which often ſerves only to alarm the horſe, and extinguiſh his courage and vigour, ſhould firſt endeavour to lead him gently towards the object that terrifies him, either by encouraging him with his voice, or by cloſing his legs upon him, to make him go up to the object that terrifies him. If he will not go towards it, you may give him the ſpurs, but with diſcretion; and by coaxing and careſſes, puſh him towards it inſenſibly. Severe correction will never cure him of this fearful temper, which is a fault inherent in his nature; nor of any imperfection in his ſight, which is a diſorder belonging to him; but the habit of view and ſmelling may, in time, remedy the defects of nature.

If, notwithſtanding, you perceive that ſloth and malice are added to theſe faults, you muſt uſe, as you find it neceſſary, both mildneſs and ſevere correction; and you will beſtow them in proportion to the effect they produce. For the reſt, be careful never to ſurprize and alarm a young horſe which is ſhy, and apt to ſtart; never terrify him with what he moſt fears; never beat him in order to make him come up to an object of which he is afraid; accuſtom him by degrees to it, and have patience; the fear of puniſhment does oftentimes more harm, and is more dreaded by him, than the very object which firſt alarmed him.

There are ſome horſes who are ſtruck with ſuch terror at the ſight of a ſtone, or wooden-bridge, at the ſound and echo of the hollow part of it, that they will fling themſelves headlong into the water, without the rider's being able to reſtrain him. They are to be cured of this apprehenſion, by covering the pavement of their ſtall with wooden planks, between two and three feet high. The horſe ſtanding conſtantly upon them, his feet will make the ſame noiſe as they do when he goes over a bridge; and he will, of courſe, grow familiar to the ſound, and loſe all apprehenſion of it.

To accuſtom them likewiſe to the noiſe of the water running under the bridge, lead him to a mill, fix two pillars directly over-againſt the wheels, and tie your horſe conſtantly for two hours together, ſeveral times in the day. Having done this, bring him back to the bridge, and let an old horſe, that is not afraid, go before him upon the bridge, by degrees you will find him go over a bridge as readily and quietly as if he had never had the leaſt apprehenſion.

For horſes that are addicted to lie down in the water, you muſt provide yourſelf with two little leaden balls, and tie them to a piece of packthread, and, in the moment that he is lying down, you muſt drop theſe into his ears; and if he riſes inſtantly, or forbears to lie down, draw them back; but this method is not leſs ſure than that of breaking a flaſk filled with water upon his head, and letting the water run into his ears.

Fire, ſmoke, the ſmell of gunpowder, the noiſe of guns, or other arms, naturally ſurpriſe and frighten a horſe.

There

There are few that will come near fire, or paſs by it, without difficulty. There are many occaſions, however, in which it is neceſſary; it is therefore proper to accuſtom your horſe to it. In the firſt place, begin with your horſe by letting him ſee it, and for that purpoſe tie him between two pillars, and hold before him, at about thirty paces diſtant, a burning whiſp of ſtraw; this ſhould be continued for ſome days together, repeating it ſeveral times each day. Let the perſon who holds the brand advance towards the horſe ſtep by ſtep; and let him take care to advance, or ſtop, often, as he perceives the horſe is moved, or leſs frightened, who, in a ſhort time, will be emboldened, and no longer afraid of the fire. After this, get upon him, carry him ſlowly, and as it were inſenſibly, towards the brand, the perſon who holds it taking care not to ſtir; if your horſe comes up to it without being frightened, let the man on foot walk on, and let the horſe follow the fire. Would you bring your horſe to go acroſs a fire, lay upon the ground ſome ſtraw about half burnt out, and he will paſs over it.

With reſpect to the noiſe of arms and drums, let your horſe hear them before you give him his oats; do this regularly every day, for ſome time, and he will be ſo uſed to them as not to mind them.

A horſe is ſaid to be *entier*, in its natural ſenſe whole, entire; and, in the figurative meaning, obſtinate, ſtubborn, opinionated, to that hand to which he refuſes to turn. A hurt in his foot, leg, or ſhoulder, may often be the cauſe of his refuſing to turn to that ſide where he feels any pain. A hurt in his reins, or haunches, a curb or ſpaving, which, by hindering him to bend, and reſt upon his hocks, may make him guilty of this diſobedience. Art can do little towards curing theſe evils; conſequently, a horſe ſo affected will never dreſs well, becauſe he never can be made ſupple and ready; beſides, every horſe is naturally inclined to go to one hand more than the other, and then he will go to that hand on which he finds himſelf the weakeſt, becauſe with the ſtrongeſt he can turn more eaſily.

It is a known fact that horſes are naturally inclined to go better to one hand than to the other. The halter, the bridle, the ſaddle, and the girths, are all put on, and tied on the left ſide; when they are rubbed or curried, the man ſtands on their left ſide; the ſame when they are fed; and when they are led out, the man holds them in his right hand, conſequently their head is pulled to the left; here is a chain of reaſons ſufficient to induce us to believe, that if they are readier to turn to one hand than the other, it is owing to a habit and cuſtom which we ourſelves have given them.

We ſeldom meet with horſes that are readier to turn to the right hand than the left; and when it ſo happens, it oftentimes denotes an ill temper; it demands much time and pains to cure them of this fault.

Note.—It is not proper to uſe ſevere correction to make a horſe obey who refuſes to turn to one hand; if he is cold and dull, he will loſe all his vigour and courage; if he is of an angry temper, hot, and briſk, you would make him deſperate and mad; work him then upon the principles of art, and purſue the method you think moſt likely to reform his ill habits, and reduce him to obedience. If he obſtinately refuſes to turn to one hand, begin the next leſſon by letting him go to his favourite hand a turn or two; finiſh him on the ſame hand, and by degrees you will gain him; whereas, were you to do otherwiſe, you might make him be ever after rebellious. A horſe that ſtrenuouſly reſiſts his rider, if he has vigour and courage after he is reduced and conquered, will, nevertheleſs, ſucceed in what you want of him, provided he is under the direction of an able and knowing perſon, who underſtands the aids of the hands and legs, and their mutual harmony and correſpondence. Such a horſe is even preferable to one who never rebels, becauſe, in this laſt, nature may be deficient, if we may be allowed the expreſſion, with reſpect to his want of ſtrength and reſolution.

In order to teach your horſe to turn to both hands, you muſt ſeparate your reins, as we have already mentioned; do not confine him too much, ſupport him moderately, ſo that you may eaſily draw his head to one ſide or the other, as you would have him go, and to give him the greater liberty to turn.

If he refuſes to obey, examine him; if he is by nature impatient, hot, and vicious, by no means beat him, provided he will go forward; becauſe being held in hand, and kept back a little, is puniſhment enough; if he ſtops, and tries to reſiſt, by running back, drive him forward with the chambriere.

The reſiſtance of a horſe whoſe mouth is faulty, diſcovers itſelf more in going forward than backward, and in forcing the hand. A horſe of this ſort ought never to be beat, he ought to be kept back, as we have juſt now ſaid; you muſt endeavour to give him a good and juſt appui, and put him upon his haunches, in order to cure him of the trick of leaning upon his bit, and forcing the hand. If your horſe is heavy, never preſs or put him together, till you have lightened his fore-part, and put him upon his haunches, for fear of throwing him ſo much upon his ſhoulders, that it may be very difficult afterwards to raiſe him. Take particular care to lighten every horſe that is heavy before, and has malice in his temper at the ſame time; for if you were to preſs him, he would reſiſt you through vice; in which caſe, by his want of ſtrength on one hand, and being heavy and unwieldy on the other, you would be expoſed to evident danger.

A reſtive horſe is one that refuſes to go forward, who ſtanding ſtill in the ſame place, defends himſelf and reſiſts his rider in ſeveral different manners; it is much to be feared that one ſhould loſe all temper with ſuch a horſe, ſince it requires a great deal of patience to cure ſo capital a fault, and which, perhaps, by habit and time, is ſo rooted in him as to be almoſt natural to him. Treat a horſe of this ſort, who has been too much conſtrained and tyrannized over, with the ſame lenity that you would ſhew to a young colt. The ſpurs are as improper to be uſed to one as the other; make uſe of your ſwitch, in order to drive him forward, as you will alarm him leſs, for the ſpurs ſurprize a horſe, abate his courage, and are more likely to make him reſtive, than oblige him to go forward, if he refuſes to do ſo.

There is likewiſe another method to puniſh a reſtive horſe, it is to make him go backward the moment he begins to reſiſt; theſe corrections often ſucceed; but the general rule is to puſh and carry your horſe forward, whenever he refuſes to advance, and continues in the ſame place, and defends himſelf either by turning or flinging his croupe on one ſide or the other; and, for this purpoſe, nothing is ſo efficacious as to puſh him forward vigorouſly.

The moſt dangerous of all defences a horſe can make, is to riſe directly upon his hinder legs, and ſtand almoſt quite ſtraight, becauſe he runs a riſk of falling backward, and in that caſe the rider would be in danger of his life. People have endeavoured to correct this vice by a method of puniſhment, which might prove dangerous unleſs given in time, and with the greateſt exactneſs.

Whenever the horſe riſes ſtraight up, throw your body forward, and give him all the bridle; the weight of your body upon his fore-parts will oblige him to come down; in the minute that his fore-feet are coming to the ground, give

give him both the spurs firm, and as quick as you can. These aids and corrections, however, must be given with the greatest caution and exactness; for were you to give him the spurs when he is in the air, he would fall over, whereas if you watch the time so as not to spur him but when he is coming down, and his fore-feet near the ground, it is then impossible he should fall backward, for then his balance is destroyed, and he is upon all his legs again, and cannot rise without first touching the ground, and taking his spring from thence; if, therefore, you give him the spurs before he is in a situation to rise again, you will punish him, and drive him forward at the same time.

This defence is still more dangerous in horses who are of a fiery temper, and weak in their haunches at the same time. These are continually apt to rise; and whatever precautions the rider may take, he is in continual danger of their coming over; the way to correct them is this; tie your horse between the pillars very short, put on a good caveson of cord, and do not suffer him to be mounted. Prick him upon the buttock with a spur, or sharp piece of iron, in order to make him strike out behind; encourage him when he kicks, and continue to make him kick, encouraging him from time to time, when he obeys; do this for a quarter of an hour every day. When you perceive that he begins to kick the moment after you so prick him, without waiting till he feels it, get upon him, hold your reins long, prick him, and let a man stand by and prick him at the same time; encourage him when he kicks, and continue to prick him, to make him do it, till he will kick readily only at the offer you make of pricking him; he ought to be brought to this point in five or six days. After this, take him out of the pillars, mount him, and trot him in the longe, and make him kick by pricking him behind; after that, let him walk two or three steps, then make him kick again, and so work him by degrees. Put him to the gallop, and if he offers to rise, prick him behind, and make him kick; nothing excels this method, to break a horse of this terrible and dangerous vice.

Those horses who are subject to kick, either when they go forward, or stand still, must be kept much together, or held in closely, to make them go backward, and you will cure them of this vice.

He who would succeed in correcting the vices of horses should never depart from this maxim; always to observe a just medium between too indulgent lenity and extreme severity; work your horse according to his strength and capacity; give your lessons in proportion to his memory; and dispense your punishments and rewards suitably to his courage and disposition. See Berenger's Hist. and Art of Horsemanship, vol. ii. ch. 1, 2, 3. See also AIDS, AIRS, APPUI, BALLOTADES, CAPRIOLES, CORRECTIONS, CROUPADES, CURVETS, ENTIER, EPAULE *en Dedans*, GALLOP, HAND, MEZAIR, PASSADE, PASSAGE, PESADE, PILLARS, PIROUETTE, RAMINGUE, RESTIVE, STEP *and Leap*, STOP, TERRE-A-TERRE, TROT, UNION, VOLTE.

RIDE, among sheep farmers, a term applied to rams, which, when they are put to the ewes, are said to be at ride. See RAM.

RIDE, in the *Sea Language*, a term variously applied. Thus, a ship is said to ride, when her anchors hold her fast, so that she drives not away by the force of the wind or tide.

A ship is said to *ride well* or *easy*, when she does not labour heavily, or feel a great strain, when anchored in an open road or bay. On the contrary, when she pitches violently into the sea, so as to strain her cables, masts, or hull, she is said to *ride hard*, and the vessel is termed a bad roader.

A ship *rides across*, when she rides with her main-yards and fore-yards hoisted up to the hounds, and both yards and arms topped alike.

She is said to *ride a-peek*, when one end of the yard is peeked up, and the other hangs down: this is also said of a ship, when, in weighing, she is brought directly over her anchor.

She is said to *ride athwart*, when her position lies across the direction of the wind and tide, when the former is so strong as to prevent her from falling into the current of the latter: and to *ride betwixt wind and tide*, when the wind hath equal force over her one way, and the tide another, so that she is in a manner balanced between them, and rides without the least strain on her cables. If the wind have more power over her than the tide, she is said to *ride wind-road*.

She is said to *ride hawseful*, when, in stress of weather, she falls so deep, that the water runs in at her hauses.

She is said to *ride portoise*, when her yards are struck down upon the deck, or when they are down a-port-last.

To RIDE *land-locked*, at sea. See LAND-*locked*.

To RIDE *by the Stoppers*. See STOPPERS.

RIDEAU, in *Fortification*, a small elevation of earth, extending itself lengthways on a plain; serving to cover a camp, or give an advantage to a post.

The word, in its original French, signifies a *curtain* or *cover*, formed from the Latin *ridellum*. Borel derives it from *ridere*.

A rideau is also convenient for those who would besiege a place at a near distance, and to secure the workmen in their approaches to the foot of a fortress.

RIDEAU is sometimes also used for a trench, the earth of which is thrown up on its side, to serve as a parapet for covering the men.

RIDEAU, in *Geography*, a river in the eastern district of Canada, which runs into the Utwas, or Ottawa. N. lat. 45° 15′. W. long. 76°.

RIDER, a town of Arabia, in the province of Hadramaut.

RIDER, in *Artillery Carriages*, a piece of wood, somewhat higher than it is broad, and of a length equal to that of the body of the axle-tree, upon which the side-pieces rest in a four-wheel carriage; such as the ammunition-waggon, block-carriage, and sling-waggons.

RIDER is also used for after-clauses, added to bills, whilst they are depending in parliament.

RIDER-*Roll*. See ROLL.

RIDERS, *Out*. See OUT-*Riders*.

RIDERS, in *Ship Building*, interior ribs, to strengthen and bind the parts of a ship together, being fayed upon the inside stuff, and bolted through all. They are mostly used in ships of war, and are variously situated, as the *floor-riders*, which are fayed athwart the keelson, and should be placed over the first futtocks. The next are the *first futtock-riders*, which fay alongside the floor-riders, and give scarph above them: these are connected by cross-chocks athwart their heels, that scarph to each side with hook and butt. The next are *second futtock-riders*, which fay alongside of the first futtock-riders, down to the floor-riders, and run up under the orlop beams. The *third futtock-riders* fay alongside the second futtock-riders, scarph or meet the heads of the first futtock-riders, and run up to the gun-deck beams. The whole are bolted together fore and aft. Breadth and top-riders, which were above the former, seem now to be discontinued

tinued in the navy, as they could only be ufeful in wake of the main and fore-chains, as the midfhips is much better ftrengthened now by uniting the fides and *fkid-beams* together by the knees.

Thefe riders ftood diagonally, fo as to faften through two or more timbers, the ftrength depending much thereon. The top-riders came up to the top of the fide, and the breadth-riders between them and the third futtock-riders, or on the broadeft part of the fhip, and hence their name. Riders are not fo much required in merchant-fhips as in fhips of war, excepting floor and lower riders in large fhips (which are generally of iron, fo as not to interrupt the ftowage), becaufe the cargo being ftowed low down, and the rigging lighter, the upper works are not fo liable to ftrain and labour, like thofe fhips of war having their heavy ordnance above the line of floatation.

RIDGE, in *Buildings*, the higheft part of the roof or covering of a houfe.

Ridge is particularly ufed for a piece of wood, in which the rafters meet.

RIDGE-*Tyle*. See TYLE.

RIDGE, in *Sea Language*, is a long affemblage of rocks, lying near the furface of the fea, fo as to intercept the paffage of a fhip under fail.

RIDGE-*Tackle*. See TACKLE.

RIDGE-*Ropes*. See ROPES.

RIDGEFIELD, in *Geography*, a poft-town of America, in Fairfield county, Connecticut; 10 miles S.W. of Danbury. This townfhip was called by the Indians "Caudotowa," or high land. It was fettled in 1709, and contains 2103 inhabitants.

RIDGES, in *Agriculture*, are pieces of ground laid up between two furrows, having always confiderable length, but different fmall breadths, according to circumftances.

It is ftated by the author of the Prefent State of Agriculture in Great Britain, that in many of the more fertile and populous diftricts, the ridges are found remarkably crooked, unequal in breadth, and made to rife towards the middle, or crown, to the height of feveral feet above the furrows, on either fide. And he fuppofes that thefe are formed in the worft manner, to anfwer the purpofes which are now intended by dividing a field into ridges. But this, he thinks, could not have efcaped the notice of all the farmers of former periods; but that, on the contrary, from the practice being fo general, it is more than probable that fuch form, though now confidered abfurd, was formerly fuppofed an improvement, as in the cafe of many other practices of antiquity; as in many of the hilly fituations in Scotland, where the foils are dry, and in a tolerably level ftate, and where cultivation had without doubt taken place at a very early period, although at prefent abandoned to the growth of heath, the ridges are found as ftraight as thofe in the beft cultivated diftricts in the kingdom. The reafon which induced the cultivators of thefe times to conftruct the ridges in fuch forms, may, he thinks, be explained in this way; that as the lands were moftly cultivated in the open field, or run-ridge ftate, the furrows of the ridges were, for the moft part, the mark or boundary between one farmer and another. The portion of land belonging to a tenant in any one place being on this account fo fmall, as to prevent him from employing any other mode of drainage, than that of raifing the ridge to fuch a height, as to permit the water to difcharge itfelf by the furrows, without injuring the crop. It is ftated, that all the ridges that are broader at one end than the other, will generally be difcovered to be the narroweft at that end which is ftill the moft wet and fpouty. It is of courfe conceived, that this form was purpofely given them, as the only means by which lands in fuch a ftate could be drained. And that, as the moft crooked ridges are found on the fteep and floping grounds, it may be fuppofed that that form and pofition were adopted by the firft cultivators, as the beft for preventing the foil from being wafhed away by fudden falls of rain, which muft no doubt have been the cafe to a greater extent, had the ridges been ftraight. Each furrow, by becoming a fort of fmall rivulet, without any thing to impede its courfe, muft have done more mifchief to the foil than if it had been gradually taken off the circuitous courfe of the crooked ridges.

But from the change in the nature of poffeffing lands, proprietors and tenants having now, except in a few open field diftricts, the means of draining and forming the ridges in the moft effectual manner, thefe old forms of ridges, which can only be ufeful in fuch cafes as the above, are not only rendered ufelefs, but operate ftrongly againft the full improvement of the foil. But notwithftanding this, there is, it is conceived, no fort of bufinefs in which the farmer can be engaged, that demands more judgment and caution than that of levelling and altering the direction of fuch forts of ridges. However, before the mode of managing this in the cheapeft and moft effectual manner is explained, it may be proper to fhew the moft fuitable forms and directions in different forts of foil, and under different circumftances of the grounds.

In forming ridges, great attention is neceffary to the nature and quality of the foil, and the particular fituation of it, as the fize, height, and direction muft, in a great meafure, be governed by them. It has been obferved by a late practical writer, that where the land is of fuch a nature as to be highly retentive of moifture, or, from the peculiarity of its pofition, liable to become too wet for the growth of ufeful crops, the ridges fhould in general be made narrower, and have a more rounded or convex form, than in the contrary cafe, or where it is expofed to injury from becoming too dry. But, in the firft cafe, they ought not, however, to be raifed fo very high as is fometimes the practice, as by fuch means much inconvenience is often fuftained from the crowns becoming too dry, and the grain ripening in a flow and partial manner. Befides, narrow ridges, with but a little elevation, are, in general, much more effectual in taking away the water that may be injurious.

It has been remarked by the writer of the Perthfhire Agricultural Report, in refpect to the height of ridges in lands of more dry defcription, that as the furrows, in general, produce lefs crop than any other part of the ground, the fewer furrows the better, provided the land can bear it. If the field be dry, there is not only more produce by fewer furrows, but the ridges are cloven by every ploughing (a thing that cannot be done in raifed ridges with deep furrows), which keeps them in an uniform level furface, and greatly facilitates the labour of fpring and harveft. Perfons who are not accuftomed to inveftigate the caufe of what they daily fee, are deterred from making their ridges nearly flat by the waters that ftagnate, in the ftrips of grafs and fprits that lie between the ridges, which they have raifed greatly in the middle: never confidering that they are working againft nature, becaufe the more the ridges are rounded the deeper are the furrows, till they become like ditches, and the more readily do clods fall down, fo that they are with their own hands producing the very evil which they wifh to prevent. Whereas, were the ftrips of flags and other trumpery torn up, were the furrows lefs deep, and kept

kept perfectly clean and open, to allow a free paſſage to the water, the whole would flow to the open drain at the extremity of the field; and the higher the furrows are, in reſpect to this drain, their relative height would make the water flow the faſter. Care ſhould always be taken that the clods that fall back into the furrows, and dam the water in ſuch land, ſhould be removed with the ſpade. The ſlovenlineſs of men in this particular circumſtance, more frequently produces the ſtagnation complained of, and all its baneful conſequences, than either ridges moderately raiſed, or any other cauſe. This he conſiders as perfectly ſatisfactory, in reſpect to laying out ſuch lands into ridges in the firſt inſtance. But that, in caſes in which neither the circumſtances of the ſoil, nor the nature of its ſituation, require that the ridges ſhould be formed in a particular manner, or of any certain breadth, that of making them about eighteen feet may be the moſt ſuitable, as they are found to anſwer well in the way of keeping the ground properly dry, and of the moſt convenient dimenſions for turning the teams at the ends in ploughing. And that beſides, the ſeed, where this method is purſued, can eaſily be ſown by one caſt up and another down; an operation which, in other circumſtances, would be attended with conſiderably more labour. That, in the covering of the ſeed by means of harrowing, the work is alſo accompliſhed with more facility and diſpatch, as by employing double implements of this kind, one turn may wholly finiſh the buſineſs. And that in the reaping, too, they have advantages, in allowing the number of reapers that are neceſſary to work with convenience, and without being in the way of each other. This, though a great advantage in ſome caſes, is of leſs conſequence ſince the mowing of grain is become more general.

But it is ſtated, that wet, clayey, or any ſtiff and tenacious loamy ſoils, where the under ſtratum is clay, ſhould be ploughed as much as poſſible into ridges of much leſs ſize, in order that they may be kept in a ſtate of dryneſs, ſuitable to the growth of the crops that are to be put upon them. Three or four feet, according to the degree of tenacity and wetneſs, may, in ſuch ſorts of land, be fully ſufficient. And it is added, that in the counties of Eſſex and Hertford, on this ſort of wet ſoils, three feet are found to anſwer the purpoſe in a very effectual manner. And that it has been obſerved in the Middleſex Agricultural Report, on the authority of much experience, that their ſuperiority over ridges of greater breadths, for taking the water off without waſhing the land, is incontrovertible. That, in ſhort, as there is much variation in lands of theſe kinds, the width and flatneſs of the ridges ſhould be increaſed as they recede from the nature of clay or clayey loam, and approach that of ſand, in order that a larger proportion of moiſture may be preſerved: while, on the contrary, as they are becoming more of a clayey quality, they ought to be narrower, and to have a more high and rounded form, that the diſcharge of injurious moiſture may be more expeditious. In loamy ſoils they ſhould be either broad and flat, or narrow and round, in ſome meaſure, according to the degree in which they approach the ſandy or clayey ſoils. And that, in very wet clayey ſoils, where they reſt upon a ſubſoil of ſome porous kind, great advantage in the way of drainage may often be obtained, by ſinking the furrows ſo deep, as to reach it. But ſome perſons, on theſe ſorts of clayey ſoils, ſuppoſe the beſt breadth to be ten or twelve feet, as where they are narrower there is much diſadvantage, though they keep the land drier. Alſo, in lands of the marſhy or fenny kinds, as moſtly approaching in ſome degree to the nature of theſe, the ridges ſhould be made narrow, and rather round in their forms.

But that as the principal defect of lands of the ſandy kind is that of parting with their moiſture too readily, and of courſe becoming quickly in a ſtate of too much dryneſs for the purpoſe of healthy vegetation, it is the moſt adviſable to plough them into very broad ridges, or even in ſome caſes quite flat, without the leaſt degree of furrow being made; as, in this way, the moiſture may be more effectually retained in ſuch ſoils, to the great advantage of the crops which are grown upon them. But in the conſtructing of ridges on ſuch ſoils as are of the boggy or moſſy kinds, ſome attention is neceſſary in reſpect to their depth, and the proportion of wetneſs that may be preſent; as where they are thin, and have but little injurious moiſture, they may be more broad and flat than where they are deep of moſs, and more retentive of moiſture: ſix or ſeven yards may, in general, be the beſt. It is obſerved, that even in the deeper ſorts, long experience has ſhewn that, in the firſt inſtance, it is improper to make them too high or too narrow; as, in the former caſe, they throw the water off from their ſides, without admitting it to penetrate their ſubſtance, the top of courſe gets too dry; while, in the latter, there is a loſs of ſurface, from too many diviſion furrows. The breadths already mentioned are found to be the beſt; and when the improvement is completed, the ridges appear like ſegments of wide circles, with a clean well-defined diviſion furrow between each of them. The moiſture is thus cauſed ſlowly to filtrate through the moſs, rendered friable by lime, until it reaches the diviſion furrows. It is generally neceſſary to clean theſe out before winter, and at the time the crop is ſown, until the moſs acquires ſolidity. This has been fully ſhewn in a paper, in the ſecond volume of Communications to the Board of Agriculture. See the work.

And it has been remarked, that ridges in theſe ſoils are generally formed by the ſpade, the workmen beginning nearly in the middle of the part which is to form the ridge, only leaving the ſpace of about eighteen or twenty inches, upon which the materials raiſed from the trenches on each ſide are depoſited, ſo as to conſtitute the crown; and in this way, digging up and turning over narrow ſpits on each ſide, the workman proceeds till he comes to the diviſion furrows, which are cut out and laid on the ſides: in which way, the ridge, when completed, appearing as if done by the plough. And in the deeper moſſy ſoils, eſpecially of the more ſpongy kind, it is probable the breadth of the ridges may be increaſed with advantage, after they have collapſed and become ſufficiently firm; as, by ſuch means, they will be more ſuitable for being laid down to graſs or ſward, for the purpoſe of paſturage.

Further, in what reſpects the general diſpoſition of ridges, where there is not a neceſſity of giving them any particular direction, either for the purpoſe of drainage, or other circumſtances, they ſhould be formed as much as poſſible in the direction of north and ſouth; as, by that means, much advantage may be gained in the crops attaining maturity, and in becoming dry, from their having the more full influence of the ſun and wind. And it has been remarked by Mr. Marſhall, in his Midland Economy, that the ſhocks, after grain has been reaped, ſhould be ſet in the ſame direction, and not have an eaſt and weſt poſition; as, in this caſe, the ſheaves on the north ſide are many days later in being in a proper condition for being conveyed to the ſtack, than thoſe on the ſouth. From further experience, he is alſo convinced of the bad effects of ridges having an eaſt and weſt direction; it having been found that corn, on the ſouth ſides of ſuch as were not by any means high, ſhot into ear, and changed and ripened a week at leaſt earlier than that on the north; and that at the time of reaping, the wheat on the

the fouth fides was, in fome patches, too ripe; while that on the north fides was, in many parts, abfolutely in a green ftate.

But where the ridges are to be conftructed in fuch lands as are hilly in their fituation, or have much declivity, it is neceffary that they be neither made too fteep, nor have too much of a horizontal direction given them; being drawn in fuch a manner, as that they may have that fort of eafy floping direction, by which the water may be taken off in a gradual eafy manner; as, in this way, there will not only be great advantage in the faving of labour in ploughing, nearly one-third lefs power in the team being fufficient; but the injury and inconvenience of heavy rains wafhing down the foil and manure will in a great meafure be obviated. It has been ftated by the author of the Gentleman Farmer, that in a hanging field, that had been carefully dreffed with lime and dung for turnips, and in which the turnips were fairly above the ground, a heavy, fummer fhower fwept down the crop, together with the lime, dung, and a portion of the loofe foil, leaving the land naked and expofed. Therefore, in the forming ridges in lands that have fuch fituations, it has been well obferved by the author of the Agricultural Report of Perthfhire, that when the fields hang fo much as to be accounted fteep, the ridges ought neither to be drawn parallel to the bottom of them, nor at right angles, ftraight up and down; either of which would be inconvenient in the ploughing, and injurious to the foil; but they ought to be drawn diagonally. The great point is to underftand in what direction this diagonal flope of the ridges ought to run. In this refpect the tenants of Balgowan, in this diftrict, are perfectly correct; and it is his wifh that their example were followed by all farmers, whofe land has a great declivity, of which there is a confiderable proportion, not only in that, but in all hilly countries whatever. The form and direction of the ridges are, he thinks, contrived with fuch judgment, that the furrow (or, as lord Kaimes with more accuracy calls it, the furrow-flice) falls eafily away from the mould-board, as well in afcending as in defcending the field, which is the principal fecret. There can be no more than two diagonal lines in any four-fided figure, which is generally the form of inclofures; and if you bring a fenfible ploughman to each of the angles below, defiring him to look towards each of the oppofite angles above, he will at once tell you which of thefe diagonal directions is eafieft for himfelf and his horfes, and will accordingly fix on that line by which the furrow, *in afcending*, will fall moft readily into its place, having his right hand and the mould-board of his plough with a fide-afpect to the bottom of the field. But, with the view of rendering this more obvious, fuppofe the field to have a fteep defcent and a fouthern afpect, the ridges are drawn from fouth-weft to north-eaft; which is the cafe in the inftance alluded to. Suppofe, again, the field to have a northern afpect, the ridges are drawn in the fame direction, but with this difference in ploughing, that you *afcend* fouth-weft in the laft cafe, whereas you *defcend* fouth-weft in the firft. If the field fronts the eaft, you afcend north-weft; or invariably four points forward from the flope of the field, in going up the hill. Befides the vaft faving in refpect to the power or ftrength of the team in this way, and that of the foil being lefs liable to be carried away by rains, by the running of the water in the furrows; where the ridges are made parallel to the bottom of the field, all the dexterity of a man and force of cattle that could be applied would be infufficient to turn every fecond furrow up againft the hill.

It is remarked, that the expedient univerfally employed, according to the old fyftem, in ploughing fields of this kind, was either to plough with a double mould-board, or, if the mould-board were fingle, to plough only one furrow in going twice the length of the ridge; but moft frequently the laft. Both are, he thinks, bad hufbandry. In the former method, you lofe none of your time, indeed; but one half of your labour is loft by the latter. His principal objection, he is of opinion, holds equally againft both. All the foil is, year after year, rolling downward; and in procefs of time, the upper part of the field will be peeled to the bone, and quite bare of foil, while a great bank is accumulating at the bottom, like a dunghill, compofed of the richeft land in the field; and withal, the furrows are laid fo completely on their backs, that little benefit is derived from the manure, excepting it be laid on the furface the firft year.

The fame writer further ftates, that where a hill is to be dreffed, in order to be laid down to grafs, it ought to receive the latter furrow by going round in a fpiral line, without ever turning the plough, beginning at the bafe, and ending at the top. This requires lefs labour, and is more beautiful. In preparing the ground for this laft furrow, it may be ploughed diagonally, to keep the foil from tumbling down hill, as has been mentioned above, in refpect to declivities: for this purpofe, the furface of the hill may be divided into three or more fections. And it is remarked by a late practical writer, in addition, that, in this way, no more ftrength of team is required in ploughing fuch elevations than in that of ploughing on a level; while, where the foil is of the gravelly or fandy kind, the great inconvenience of the moifture going off too quickly is guarded againft, by its being detained in the furrows. And the fpiral furrow is, according to the firft writer, the neateft method of finifhing off a lawn, even of flat land, near a gentleman's houfe; as it brings the whole furface to an uniform appearance, and pleafes the eye more than having the lawn ftriped with furrows.

In regard to fuch lands as are level, or have but little inequality of furface, the beft general practice, it is obferved by the author of a late work, is to form the ridges as ftraight and as regular in refpect to breadth as poffible; as, by having them crooked, and of irregular breadths, the water is not only liable to ftagnate and injure the foil, but the friction in ploughing is greatly increafed, and the furrow-flice is not fo well laid over, being more difpofed to fall back. And, befides, many unneceffary turnings are requifite, on account of the inequalities of breadth, by which much time is loft, as well as much trouble given to the ploughman in managing the plough while at work.

In fome of the lefs improved counties in the northern parts of the kingdom, as Lancafhire, and thofe adjoining it, the ridges on the old lands are often narrow, crooked, and very ill laid out, being for the moft part too much rounded in the middle parts, and in the form of butts, which are the ftates in which they are at the prefent time, few or no attempts having been made to alter them in any way. However, from the nature and depths of the foils, it would not appear that there would be any danger or difficulty in doing it; though this may be the cafe in fome other fituations, where it ought to be attempted with proper caution. In fome parts of the above diftrict, as that of the field, the term *farring* or furrowing is often made ufe of, inftead of that of ridge.

Method of Levelling and Straightening old Ridges.—In fuch kind of land as has been long in a cultivated ftate, high, crooked, and irregular ridges are frequently met with, that often become neceffary to be altered, fo as to be rendered more ftraight and level. This, though apparently fimple, is is a matter of more difficulty and trouble, and which demands more knowledge and care in its execution, than is commonly fuppofed by perfons unacquainted with the bufinefs. Various obltacles have been thrown in the way of this fort of improvement by farmers in different diftricts. By fome the expence is confidered as very great, while others oppofe it on the ground of the injury done to the land for fome years afterwards. And according to the Agricultural Report of the county of Perth in Scotland, the objection made by fome farmers in the Carfe of Gowrie is this: in the action of levelling ridges, that have been, time immemorial, raifed high in the crown, much foil is brought up, which for ages had neither feen the fun nor fmelled the air. This, like moft other foils, which has been fo long and fo deep buried, is very unproductive at firft, and blafts all their expectations. It is perfectly confonant to the procefs of nature, the writer fuppofes, that this fhould, in fome meafure, happen; and, as far as it has any weight, is an argument not only againft levelling, but againft ftraightening the ridges of fuch land. But was not, he afks, every particle of that foil, which is fo much reprobated, on the furface of the ground before the ridges were fo raifed by the hand of man? Was not this very foil, at that time, as good as any foil in the field? Nay, was it not much more fertile before it was buried in the middle of the ridge, than the *new* foil, which the ploughman was digging up year after year, out of the fterile furrow, to affift in gradually raifing his ridge higher? Every man muft anfwer in the affirmative. If you therefore bring back your land nearly to the level in which the hand of nature left it, you will find the very foil, which had been fertilized by the deciduous parts of plants, from the creation, until it came into cultivation; the foil which Providence intended for the production of grain for the ufe of man, this foil has not furely loft its fertility, although that fertility has lain long dormant by its being covered up in the bowels of the earth, and removed from the benign influence of heaven. The fertility of a foil cannot be exhaufted by any other means, but by over-cropping. It may be fufpended, as in this inftance, but not annihilated. Reftore the foil to its native place, and to that influence of which it was deprived, and it will foon become equally productive as at firft. It is not pretended that its fertility will be exerted all at once. Clay is a ftubborn foil: it is neither fo eafily ftimulated by manure, nor by the benignity of the atmofphere, as other foil. It requires time and labour and expence to fet it in motion; but when moved it retains its powers longer and makes very ample returns. And in addition to thefe obfervations, vaft benefits muft in many cafes refult from bringing ill-formed ridges into a proper fituation for the advantageous culture of crops upon them.

With regard to the time or feafon for the execution of this fort of work, it has been remarked that the moft fuitable period for accomplifhing it where the plough is employed, is when the land is undergoing a courfe of repeated ploughings, as in the cafe of a fallow; as under fuch circumftances the more elevated parts of the field may be ploughed over as often, and in fuch directions, as is moft fuitable for bringing them into a level ftate. Where the ridges are not raifed to any very confiderable height in their middles, but badly formed in other refpects, they may fometimes be readily brought into proper order by being fplit, or cloven down occafionally; a mode which is performed by beginning at the furrows and terminating at the crown or middle of the ridge, fo that the former furrows become the crowns, and the new furrows are made in the middle of the old ridges, which being filled by a furrow from each fide, has the tendency of foon bringing them into a more equal and level form. But that in cafes where the foil is of the light, gravelly, or open and mellow kind, the plough may be conveniently employed in levelling the ridges, without producing any injury of confequence to the crops that may afterwards be put upon the land. It is proper, however, even in lands of thefe kinds, to ufe fuch caution in performing the operation, in order to avoid the injury that might be caufed by too large a proportion of the under foil being brought to the furface in different parts of the ground, and in that way rendering it lefs productive in crops than it was before.

It has been contended, however, by Dr. Anderfon, in the firft volume of his Effays, that where this fort of work is done by fuch implements as are contrived for expeditioufly bringing high ridges to this fituation, as ploughs, harrows, drags, &c. the farmer of neceffity buries all the good mould that was on the top of the ridges in the old furrows; by which he greatly impoverifhes one part of his field, while he too much enriches another; infomuch, that it is a matter of great difficulty, for many years thereafter, to get the field brought to an equal degree of fertility in different places: which makes it impoffible for him to get an equal crop over the whole of his field by any management whatever: and he has the mortification frequently, by this means, to fee the one half of his crop rotted by an over-luxuriance, while other parts of it are weak and fickly, or one part ripe or ready for reaping, while the other is not properly filled; fo that it were, on many occafions, better for him to have his whole field reduced at once to the fame degree of poornefs as the pooreft of it, than have it in this ftate. An almoft impracticable degree of attention, in fpreading the manures, may indeed in fome meafure, he thinks, get the better of this difeafe: but it is fo difficult to perform this properly, that he has frequently feen fields that had been thus levelled, in which, after thirty years of continued culture and dreffings, the marks of the old ridges could be diftinctly traced when the corn was growing, although the furface was fo level that no traces of them could be perceived when the corn was off the ground. But this, he remarks, is a degree of perfection in levelling that cannot be ufually attained by following this mode of practice, and therefore it is but feldom feen; for all that can be expected to be done by any levelling machine is to render the *furface* perfectly fmooth and *even* in every part at the time that the operation is performed: but as in this cafe the old hollows are fuddenly filled up with loofe mould to a great depth, while the earth below the furface, upon the heights of the old ridges, remains firm and compact, the new-raifed earth, after a fhort time, fubfides very much, while the other parts of the field do not fink at all; fo that in a fhort time the old furrows come to be again below the level of the other parts of the field, and the water, of courfe, is fuffered in fome degree to ftagnate upon them, infomuch that in a few years it becomes neceffary once more to repeat the fame levelling procefs, and thus renew the damage that the farmer fuftains by this pernicious operation. He therefore thinks that on thefe accounts, if the farmer has not a long leafe, it will be found, in general, to be more for his intereft to leave the ridges as as he found them, than to attempt to alter their direction: and if he attends with due caution to moderate the height of thefe old ridges he may reap very good crops, although, perhaps, at a fomewhat greater expence of labour than he would have been put to upon the fame field, if it had been reduced to a proper level furface, and divided into ftraight and parallel ridges. However, where a man is fecure of poffeffing his ground for any confiderable length of time, the advantage that he will reap from having level and well laid out

out fields are fo confiderable, as to be worth purchafing if it fhould even be at confiderable expence. But the lofs that is fuftained at the beginning by this mechanical mode of levelling ridges, if they are of confiderable height, is fo very great, that it is, perhaps, doubtful if any future advantage can ever fully compenfate it. On thefe grounds he rejects the ufe of machinery in thefe operations, and recommends the method defcribed below as being more efficacious and fuccefsful. There have, however, of late been many valuable machines contrived for the purpofe of accomplifhing the work in an eafy and cheap manner, and which have been found to anfwer in practice. An implement of this fort has been defcribed under the head machine. See MACHINE *Land Levelling*.

But where the lands are of the clayey, loamy, or tenacious wet quality, there is much greater difficulty, as well as greater attention required, in levelling down and changing the forms of the ridges, as it frequently happens that in fuch foils, after the earth from the crowns has been removed in order to render them level, a coarfe, unfriendly, ftiff foil is brought up, as has been feen above, that requires a great length of time and much amelioration to bring into a ftate capable of fupporting good crops of any fort of grain. In thefe cafes and forts of foils, in the ftraightening and bringing down the ridges on the coarfe lands in the northern parts of the ifland, the author of the Perth Agricultural Report advifes it as proper to begin the operation by removing the made or ameliorated foil on the crown of the ridge to one fide, which may, he thinks, be done by two or three ploughings in one direction, turning the furrow always one way. This is eafier than doing it with the fpade. Then fuch a quantity of the buried foil may be caft with the fpade from the crown of the ridge, as will fill up the furrows at pleafure; and, laftly, the ameliorated foil may be fpread over the furface of the whole. If it is not thought enough to fave the ameliorated foil on the crown of the ridge alone, firft one fide of the ridge may be taken, and then the fame procefs repeated on the other; by which means almoft all the wrought foil may be kept on the furface. A good fummer fallow and a hearty dofe of lime, and the mixture of wrought mould, will reanimate the new foil, and reftore its vegetative power to its primitive ftate; and a very few feafons will naturalize the whole foil, while the farmer has the advantage of ftraight ridges, moderately raifed. Some, however, think that this bufinefs may be beft performed by the fpade, though it is now obvioufly impoffible in many fituations from the vaftly increafed expence of labour. Where this mode is to be employed, it is advifed by Dr. Anderfon, in his Effays on Agriculture and Rural Affairs, to let a number of men be collected, with fpades, according to the extent of work, and then fet a plough to draw a furrow directly acrofs the ridges of the whole field intended to be levelled. Divide this furrow into as many parts as labourers, allotting to each a ridge or two, more or lefs, according to the number and height of the ridges, and other circumftances. Let each of the labourers have orders, as foon as the plough has paffed that part affigned him, to begin to dig in the bottom of the furrow that the plough has *juft* made, about the middle of the fide of the old ridge, keeping his face towards the old furrow, working backward till he comes to the middle of the old ridge, going deeper as he advances, fuitable to the height he has to bring down; then let him turn towards the other furrow, and repeat the fame on the other fide of the ridge, fo as to leave the bottom of the trench he has thus made acrofs the ridge, entirely level, or as nearly fo as poffible. When he has finifhed that part of the furrow allotted to him, which the plough has made in going, let him then go and finifh in the fame manner his own portion of the furrow which the plough makes in returning. In this manner each man performs his own tafk through the whole field, gradually raifing the old furrows as the old heights are depreffed.

And the old furrow ought to be raifed to a greater height than the middle of the old ridges, fo as to make allowance for the fubfiding of that loofe earth. And the operation is thus finifhed at once. He recommends the making of thefe temporary or crofs ridges 40 or 50 yards broad at leaft: for although fome time will be loft in turning at the ends of the broad ridges, the advantage that is reaped by having few open furrows is more than fufficient to counterbalance this lofs: and in order to moderate the height that would be formed in the middle of each of thefe great ridges, it will always be proper to mark out the ridges, and draw the *furrow* that is to be in the middle of each, fome days before you collect your labourers to level the field, to prevent any hurry or lofs of labour in the future operation of levelling. The field will thus be reduced at once to a proper level, and the rich earth that formed the furface of the old ridges will ftill be kept on the furface of the field to be formed into new ridges. And the fame writer adds, that the direction of the ridges, as noticed before, ought to be north and fouth, if the field will permit, by which means the eaft and weft fides of the ridges, dividing the fun equally between them, will ripen at the fame time. Alfo further, that when the foil is fo wet as to require the raifing of the ridges, they ought to be made twelve feet wide, and twenty inches high, and to be preferved always in the fame form, by *cafting*, that is, by ploughing two ridges together, beginning at the furrow that feparates them, and ploughing round and round till the two ridges be finifhed. The feparating furrow is indeed raifed a little higher than the furrows that bound the two ridges, but at the next ploughing that inequality is corrected by reverfing the operation, which is eafily done.

And in regard to the expence of the different methods, the following ftatements are given by the fame writer, which, though far below the prefent price of labour, may furnifh the means of calculation to the improver. Suppofing the price of labour in Scotland to vary in different places from fixpence to one fhilling, and that the medium price be fixed at nine-pence a day; and that the hire of a plough, with four horfes and two fervants (for fo many, in general, will be requifite to labour properly ground in the condition that this is fuppofed to be in), varies in like manner from three to five fhillings *per* yoking, and that the medium price of this be called four fhillings; in this cafe the comparative expence of levelling, by thefe two different modes, would be as follows.

Expence of Levelling by Spade.

	£	*s.*	*d.*
For wages to eleven labourers one day, at nine-pence each - - - - -	0	8	3
For the hire of a plough $2\frac{1}{2}$ yokings, at four fhillings each - - - - - -	0	10	0
Total expence of one day's work - -	0	18	3

Expence of Levelling by Plough and Harrows.

	£	*s.*	*d.*
For two yokings and a half of a plough, as before - - - - - - -	0	10	0
For harrowing ditto, fuppofed at one-fourth of the ploughing - - - - -	0	2	6
	0	12	6

Total

	£	s.	d.
Total for once ploughing, &c. - -	0	12	6
The same five times more repeated - -	3	2	6
Total expence of levelling by plough and harrow - - - - - - -	3	15	0
Total expence of levelling by the spade	0	18	3
Difference	2	16	9

But another method practised by Mr. Paterson of Castlehuntley is, according to Dr. Robertson, first to open up with the spade a trench of about ten feet broad, from end to end of the field, in the same direction that the ridges are to be made. The upper surface of the ten-feet trench is laid upon one side, to be removed afterwards. Then the under soil of this trench is levelled and dressed by the spade and wheel-barrow, or carts, if necessary, at the same time giving the land a gentle fall at both ends, to enable the water to run off in the furrows towards the main drains. When this under soil has got its proper shape, he marks off another ten-feet trench, and with the spade throws the upper soil of the second trench on the new-formed under soil of the first trench, so as to cover it completely and equally: and so on through the whole field. The upper soil of the first trench was carried round in carts, and laid on the under soil of the last trench. The appearance of the field was then regular, rising in the middle and falling at both ends. He recommends ridges eighteen feet wide. The whole expence is supposed to be 8*l.* an acre. And it is observed in the third volume of the Farmer's Magazine, that ridges in enclosed lands are capable of being straightened with profit, or at least without loss, by wearing down the high ridges by the preceding crops, so as not to leave too much to the fallow, which is by turning one field at least into turnip or fallow every year until the whole is gone over. For as the land is ploughed and harrowed over and over in all directions, until it is brought to a close fine mould, the ridges may then be laid off just as the farmer pleases, without any loss. But that in straightening without this previous operation, the loss cannot be calculated. The advantages are therefore obvious to every man.

A writer in the fifth volume of the same work also observes, that in wet clayey soils, where the operation is undoubtedly most difficult to execute, he has accomplished the business with facility in this way. On dry soils, very little judgment or skill is required to do it, with safety to the ground, and advantage to the occupier. He states, that in 1794 he fallowed and straightened a field of about thirty acres, which had been oats the preceding year. The soil was a wet clay, and the ridges were very unequal in breadth, from ten to thirty feet, intermixed with *butts* or *gussets*, which are always detrimental to such lands, as they occasion the ploughs, &c. to turn often upon the other ridges, by which means the prints or marks of the horses' feet are left unfilled up. The first operation consisted in cleaving down the ridges. The field was then ploughed across, and thoroughly harrowed; but before the broad ridges could be brought to a level, several ploughings were necessary, which were accordingly given. The season, however, was far advanced before these necessary operations could be effected; and, as lime could not at this time be applied with advantage, he was under the necessity of laying it up in heaps, in an adjacent grass field, so as it might be expeditiously laid on whenever the field was straightened. The next consideration was, to form the ridges in such a manner as to prevent water from stagnating upon the ground. With this view, he run them partly east and west, and partly north and south, as the level would admit. When the ridges were thus formed and gathered up, the lime was applied, and a good cross-harrowing given, in order to fill up the furrows. And it being now the latter end of October, and the weather very wet, he thought it advantageous, in giving the seed furrow, to yoke the horses in line, and not a-breast, as is the usual practice. The whole field was sown on the 6th and 7th of November, and the braird appeared about the beginning of December. The weather having been wet for some days after the wheat was sown, it appeared rather thin in March, but always retained a dark green colour. It improved much during the summer months; and at harvest, turned out as good a crop as ever he saw upon such poor wet soil, the produce *per* acre being from thirty-two to thirty-four Winchester bushels of good marketable grain. Next year he ploughed the field again, and sowed one half with oats, and the other half with peas, both which were as good crops as could be expected. Perhaps it may be thought that he should have sown grass seeds among the wheat; but it is his opinion, that when ridges have been altered, a second fallowing is necessary before the field can be profitably laid down to grass. Last year he straightened a field in the above-mentioned way, which has answered his expectations to the full. It was sown with grass seeds, which at present promise well. He concludes by observing, that the advantages resulting from the practice of straightening ridges are obviously many and great. More work is performed both by plough and harrows, and to better purpose, in a given space of time: much seed too is saved; for when the ridges are at or below eighteen feet in breadth, which they ought never to exceed, two casts will suffice: whereas, in their former state, three, or even four casts, will be necessary in some parts, and in others one will be too much. Straightening ridges, and making them all of one size, also greatly furthers harvest work, as it is well known, that shearing is more expeditiously performed upon them, than upon those that are unequal with one another, or such as are broad at one end and narrow at the other. The last, though not the least advantage, which he shall notice at present, is, that wheat is not so apt to canker upon straight as upon crooked ridges. He will not now inquire how this comes to be the case; but leave it to the consideration of those who delight in abstract philosophical researches: it is sufficient for him to be assured, from experience, that it is so. The business of straightening and levelling ridges, in many situations, certainly demands much more attention than it has hitherto met with by the farmer and land proprietor.

But besides these modes of ridging, which are necessary in laying out lands for the purpose of tillage, there are others that become requisite in consequence of the growth of particular sorts of crops, and the particular methods of husbandry by which they are cultivated. Thus we have one, two, and three, or more *bout* ridges, according as the crops are grown to most advantage, on one or other of these sorts of small ridges, or as they suit the different sorts of tools by which they are put into the ground. Some other local modes likewise occur in tillage districts, of forming small ridges, for the cultivation of different kinds of crops. See TILLAGE.

RIDGES, in *Gardening*, portions of ground laid up by means of the spade in a narrow strip, to the height of one, two, or more feet, for the purpose of receiving the benefit of frosts and the influence of the atmosphere, and thereby become more mellow, light, and friable, as well as more fertile and productive. See RIDGING.

RIDGE-*Work*, in *Agriculture*, that sort of tillage which is executed

executed in the ridge method, or by raifing the furface of the land into fome kind of ridges.

RIDGES *of a horfe's mouth*, are wrinkles or rifings of the flefh in the roof of the mouth, running acrofs from one fide of the jaw to the other, with interjacent furrows.

It is commonly in the third or fourth ridge that the farriers ftrike with the horn, in order to bleed a horfe whofe mouth is overheated.

RIDGIL, in *Rural Economy*, a male fheep, in which the tefticles do not come properly down into the fcrotum.

RIDGIL *Lambs*, fuch as have none, or only one tefticle, in the fcrotum or cod. There is often great trouble and danger in thefe forts of animals being mixed with other fheep ftock, as they not only teafe the ewes, but frequently injure them. The lambs fhould, of courfe, always be cut while young, as from fix to ten or twelve weeks old, though the operation may be performed with fafety at a much later period, and even when a year or more old. Mr. Marfhall, in his Norfolk Economy, defcribes the manner of doing it in this way, where only one of the tefticles had come down or entered the cod. Having cut off the end of the fcrotum, bag, or cod, the tefticle was drawn out in the ufual manner of gelding. The other was taken out at the fide contrary to that on which the palpable tefticle was placed. In performing which, the lamb is laid flat on its fide upon the ground, being held in that pofition by one man, keeping its neck and fore legs clofe down, while another ftretches it out by drawing the hind legs backwards, keeping them tight down, fo that the animal cannot ftir. The operator then clips off a fmall patch of wool, about the fize and fhape of a duck's egg, clofe below the loin, and in the middle between the huckle and the fhort ribs; after which he makes an incifion, fufficiently wide to admit his forefinger, with which he fearches for the ftone and brings it out, difengaging it from the tunic or coat in which it is enclofed by a knife, drawing out the cord or ftring. The orifice after this is carefully fewed up, and the wounded parts anointed with elder or fome other ointment.

And it is ftated as remarkable, that the concealed tefticles all laid on the fame fide, namely the right fide; the contrary fide to that on which females are cut, in the cafes he had the operation performed in. And that in one the operation was rendered difficult by the tefticle being very fmall, and braced up clofe to the vertebræ. It is likewife added, that the palpable tefticle being priorily extracted, increafes the difficulty of the operation, as the perfon who performs it does not know which fide to cut on, and is fometimes obliged to cut on both before he finds the concealed tefticle.

This is a nice operation, which requires much care and attention in the perfon who performs it.

RIDGING *of Ground*, in *Gardening*, the practice of throwing it up into high ridges in order to lie fallow in winter, &c. to mellow, and improve in its quality and fertility.

It may be noticed, that this is a work of great utility in the kitchen garden, as well as in other parts, but more efpecially in ftiff heavy foils, and cold wet lands. It is accomplifhed by trench-digging the ground over, laying the earth of each trench in a raifed, rough ridge, lengthways, that by thus lying as high, open, and hollow as poffible, it may meliorate and fertilize more effectually by the weather during the winter. And it receives further improvement from the levelling it down again, which is expeditioufly effected, for the reception of the intended feeds, plants, roots, &c. which breaks, divides, and pulverizes the earth ftill more effectually.

And this fort of ridging is generally performed, either in the latter end of autumn, or any time in winter, or early in the fpring, as the ground is the moft vacant at thofe feafons, and not generally immediately wanted for any principal fowing or planting.

This fort of work is executed by beginning at one end of the plat of ground, and digging out a trench one or two fpades in width, and a full fpade's depth, removing the crumbs from the bottom, in the lengthways acrofs the ground, and wheeling the earth to the finifhing end, to be ready to fill up the laft trench: fo marking out a fecond trench clofe to the firft, of the fame width, then proceeding in the trenching and ridging, previoufly paring the top of the fecond trench, with all weeds, rubbifh, or dung thereon, if any, into the bottom of the firft, and then digging the ground of the fecond along regularly, the proper width and depth as above; turning the earth fpit and fpit into the firft open trench, laying it in a raifed ridge lengthways thereof, without breaking it fine, fo that it may lie fomewhat rough and hollow, according as the nature of the foil may admit: proceeding thus with another trench in the fame manner, and continuing the fame with the whole, trench and trench, to the end of the plat of ground; filling up the laft trench with the earth of the firft opened, laying it now ridgeways, as in the preceding trenches.

But in the work of levelling down ridged ground, as wanted, it fhould proceed regularly, ridge and ridge, longways, levelling the earth equally to the right and left, loofening any folid parts, and breaking all large rough lumps and clods moderately fine; forming the whole in an even regular furface, in order for fowing and planting, as required.

And in general, it is not advifable to lay down more than can be fown the fame or next day, while the furface is frefh ftirred, efpecially in broad-caft fowing and raking in the feed, as, moft generally, all tolerably light mellow foils are more yielding to the rake while the furface is frefh moved; or before rendered wet by rain, &c.; or very dry and hardened in the top earth by the fun, air, and winds, in dry weather, in the fpring months, &c.; and likewife for fowing feeds by bedding in and covering in with earth from the alleys, &c. or with earth raked off the beds for that purpofe, it would generally be moft fuccefsful to perform it in a frefh ftirred furface; though it is not fo material in drill fowing; and befides, when feeds are committed to the earth, while it is in a frefh turned up furface, efpecially in a dry feafon, they are more forwarded in a free regular germination than in ground that has lain fome time after digging or levelling down. Though fome grounds, of a wet, or heavy, ftiff nature, fometimes require to lie a few days after digging or levelling down, in order for the rough cloddy furface to mellow in fome degree, either by drying a little, or by having a moderate rain, or fometimes both, to meliorate the lumpy clods, pliant to the rake, in the cafe of broad-caft fowing, and raking in the feed.

RIDGING-*up*, in *Hufbandry*, a term ufed to fignify the practice of laying up the mould or foil to the rows of particular forts of crops, as thofe of the pea, potatoe, turnip, cabbage, and other fimilar kinds. It alfo implies the laying up land or earth in fuch a manner as that it may receive the moft full and perfect benefit and influence of the atmofphere, and in confequence become in a mellow and pulverized ftate. It is often very neceffary in ftiff lands.

RIDGLET, in *Agriculture*, a provincial word, ufed to fignify a fmall ridge, efpecially when raifed by baulking or ridging up with the plough.

RIDGLING, in *Rural Economy*, the male of any beaft that

that has been partially caſtrated, or which is not properly formed in the cod.

RIDICULE, in *Ethics*, is commonly uſed in the ſame ſenſe with irriſion; and has for its objects the abſurdities and misfortunes of mankind. The latter, however, are very improper objects of ridicule, whoſe province ſhould extend only to the careleſsneſs, inconſtancy, humour, affectation, impertinence, and in ſhort all the leſſer follies and imperfections of mankind. Such are generally the ſubjects of Horace's Satires; and Dr. More obſerves, that irriſion, which is the parent of ridicule, was the original of ſatire.

Dr. Campbell (Philoſ. of Rhet. vol. i.) obſerves, that ridicule is not only confined to queſtions of leſs moment, but is fitter for refuting error than for ſupporting truth, for reſtraining from wrong conduct, than for inciting to the practice of what is right. It is not properly levelled at the *falſe*, but at the *abſurd* in tenets; and it is not the criminal part of miſconduct which it attacks, but that we denominate ſilly or fooliſh. With regard to doctrine, it is not falſity or miſtake, but palpable error or abſurdity (a thing hardly confutable by mere argument) which is the object of contempt; and conſequently thoſe dogmas are beyond the reach of cool reaſoning which are within the rightful confines of ridicule. This ſtatement is obviouſly inconſiſtent with the mode of arguing adopted (very improperly, as we conceive) by thoſe who make ridicule, or raillery, the teſt of truth. To this claſs we may refer a noble writer, who, in his "Characteriſtics" (vol. i.) after alleging that truth may bear *all* lights, obſerves, that *one* of thoſe principal lights or natural mediums, by which things are to be viewed, in order to a thorough recognition, is *ridicule* itſelf, or that manner of proof by which we diſcern whatever is liable to juſt raillery in any ſubject. So much, at leaſt, is allowed by all, who at any time appeal to this criterion. His advocates, however, have aſſerted, that unjuſt repreſentations have often been given of the poſitions which he has maintained in his "Eſſay on the Freedom of Wit and Humour," and it has been ſaid, particularly in the "General Dictionary," that he was very far from vindicating a vague, indecent, and boundleſs ridicule, or inclined to employ his wit and humour otherwiſe than under certain reſtrictions, and when particular occaſions called for and juſtified it. Although it be allowed, that his lordſhip has been in ſome inſtances miſunderſtood and miſrepreſented, and he has written in a manner ſo inaccurate and unguarded, as to have ſubjected himſelf to juſt animadverſion and cenſure, Dr. Brown, in his "Eſſays on the Characteriſtics," has animadverted on his lordſhip's reaſoning; and with great ingenuity contended, that though ridicule is a ſpecies of eloquence, reaſon alone is the detector of falſehood, and the teſt of truth; that ridicule can never pretend to this character; that it is one of the moſt powerful engines by which error can be maintained and eſtabliſhed; and that its proper object is folly of conduct, and chiefly affectation. Other writers have defended his lordſhip, among whom we may reckon the Rev. Mr. Charles Bulkley, an ingenious and learned diſſenting miniſter. In a work aſcribed to Mr. Ramſay, the painter, the author has attempted to ſhew, that ridicule is of two kinds, and that it may be applied to opinions as well as to manners. The uſual objects of ridicule are, indeed, certain improprieties and peculiarities of character and conduct, and to aſſert, in general, that it is the teſt of truth, is advancing a falſe poſition. Reaſon is undoubtedly the genuine and proper teſt of truth. Nevertheleſs, ridicule may in ſome caſes be juſtly applied to opinions. There are tenets ſo flagrantly abſurd, that it is not eaſy to refrain from viewing them in the light of humour and raillery, and perhaps the beſt way of expoſing them may be to diſplay them in that light. Nevertheleſs, it muſt be acknowledged, that ridicule, when applied to grave and important ſubjects, is a very dangerous weapon; that it ought to be adopted with the utmoſt diſcretion, and that it has often been made uſe of in an improper manner.

With regard to conduct, ſays Dr. Campbell, we may diſcover to what kind ridicule is applicable, by directing our attention to the different departments of tragedy and of comedy. In the laſt it has a mighty influence: but into the firſt it never legally obtains admittance. Thoſe things which principally come under its laſh are aukwardneſs, ruſticity, ignorance, cowardice, levity, foppery, pedantry, and affectation of every kind. But againſt murder, cruelty, parricide, ingratitude, or perfidy, to attempt to raiſe a laugh, would ſhew ſuch an unnatural inſenſibility in the ſpeaker, as would be exceſſively diſguſtful to any audience. To puniſh ſuch enormities, the tragic poet muſt take a very different route. It ſhould be carefully remembered, ſays our author, that where nothing reprehenſible, or ſuppoſed to be reprehenſible, either in conduct or ſentiment, is ſtruck at, there is properly no ſatire (or, as it is ſometimes termed, pointed wit), and conſequently no ridicule. We may here obſerve, that the words "banter" and "raillery" are uſed to ſignify ridicule of a certain form, applied, indeed, more commonly to practices than to opinions, and oftener to the little peculiarities of individuals, than to the diſtinguiſhing cuſtoms or uſages of ſects and parties. The only difference in meaning between the two terms is, that the firſt generally denotes a coarſer, the ſecond a finer ſort of ridicule; the former prevails moſt among the lower claſſes of the people, the latter only among perſons of breeding. Dr. Campbell, after remarking that an air of ridicule in diſproving or diſſuading, by rendering opinions or practices contemptible, hath occaſionally been attempted with approbation by preachers of great name, ſuggeſts the abſolute neceſſity, in the uſe of it, of the greateſt care and delicacy, that it may not degenerate into a ſtrain but ill adapted to ſo precious an occupation.

Our author cites the authority of Ariſtotle in favour of the general principles with regard to the ſubject of ridicule which he has endeavoured to eſtabliſh. "The ridiculous," ſays the Stagyrite, "implies ſomething deformed, and conſiſts in thoſe ſmaller faults, which are neither painful nor pernicious, but unbeſeeming: thus a face excites laughter, in which there are deformity and diſtortion without pain." Ariſtotle here ſpeaks of ridicule, not of laughter in general; and not of every ſort of ridicule, but ſolely of the ridiculous in manners, of which he has, in few words, given a very appoſite deſcription. Laughter is not his theme, but comedy and laughter, only ſo far as comedy is concerned with it; and the concern of comedy reaches no farther than to that kind of ridicule which relates to manners. For an account of Hobbes's theory of laughter and Dr. Campbell's objection to it, ſee LAUGHTER.

On the ſubject of laughter, Dr. Hartley (Obſ. on Man) remarks, that young children do not laugh aloud for ſome months. The firſt occaſion of doing this ſeems to be a ſurpriſe, which brings on a momentary fear firſt, and then a momentary joy, in conſequence of the removal of that fear, agreeably to what may be obſerved of the pleaſures that follow the removal of pain. This may appear probable, inaſmuch as laughter is a naſcent cry, ſtopped of a ſudden; and alſo becauſe, if the ſame ſurpriſe, which makes young children laugh, be a very little increaſed, they will cry. As children learn the uſe of language, they learn to laugh at ſentences or ſtories, by which certain alarming notions and expectations are raiſed in them, and again diſſipated inſtantaneouſly.

taneously. Children, and young persons, are diverted by every little jingle, pun, contrast, or coincidence, which is level to their capacities, even though the harshness and inconsistency, with which it first strikes the fancy, be so minute, as scarcely to be perceived. And this is the origin of that laughter which is excited by wit, humour, buffoonery, &c. The most natural occasions of mirth and laughter in adults seem to be the little mistakes and follies of children, and the smaller inconsistencies and improprieties, which happen in conversation in the daily occurrences of life; inasmuch as these pleasures are, in great measure, occasioned, or at least supported, by the general pleasurable state, which our love and affection to our friends in general, and to children in particular, put the mouth and body into. For this kind of mirth is always checked where we have dislike; also where the mistake or inconsistency rises beyond a certain limit; for then it produces concern, confusion, and uneasiness. This account of the original of laughter, and also of its salutary effects which the author mentions, both with respect to the body and mind, is inconsistent with Hobbes's theory, to which we have above referred. The laughter of pride and contempt, and the ridicule connected with it, are very different, not only in their origin, but in their influence.

RIDICULE, in a *Comedy*. See COMEDY.

RIDICULI ÆDICULA, or the *Chapel of Laughter*, in *Roman Antiquity*, was a building erected at Rome, about two thousand paces beyond the gate Capena, in memory of the flight of Hannibal from the siege of the city, on account of the ruin and tempest that befel him on that occasion. The Romans, in ridicule of his flight, built and consecrated this chapel.

RIDING, a corruption of *trithing*, a division of Yorkshire, of which there are three; *viz.* the East-riding, West-riding, and North-riding.

In indictments, in that county, it is necessary that the town and riding be expressed. See REGISTER.

RIDING *Academy*. See ACADEMY and MANEGE.

An academy for riding was founded in this country, by king William III. See RIDE.

RIDING *Armed*, with dangerous and unlawful weapons, is an offence at common law. (4 Inst. 160.) By the statute 2 Edw. III. cap. 3. none shall ride armed by night or day, to the terror of the people; or come with force and arms before the king's justices, &c. doing their office, upon pain to forfeit their armour, and suffer imprisonment at the king's pleasure; and a fine may be set upon them by the justices, by 20 Ric. II. cap. 1. And no person can excuse the riding armed, in public, by alleging that he wears armour for his defence against an assault; but men may wear common arms, according to their quality and the fashion, and have attendants with them armed agreeable to their characters: also persons may ride or go armed to take felons, suppress riots, execute the king's process, &c. 3 Inst. 162.

RIDING *Cast*, in *Husbandry*, a term used by the farmers for a particular method of sowing their grounds, by making two casts upon the ground at the same time. This is not much used, but it is a quicker way than the double cast, which is the method now most used. Plot's Oxfordshire, p. 251.

RIDING-*Clerk*, one of the six clerks in chancery, who in his turn, for one year, keeps the controlment-books of all grants that pass the great seal that year. Blount.

RIDING-*Bitts*, in *Ship Building*, are the largest bitts in a ship, and those to which the cable is fitted when she rides at anchor.

RIDL, in *Geography*, a town of Austria; 10 miles S.S.W. of Aigen.

RIDLEY, NICHOLAS, in *Biography*, an eminent English prelate, and martyr to the cause of the reformed religion, descended from an ancient family in Northumberland, was born early in the 16th century. As he exhibited early proofs of good natural abilities, he was placed in a grammar-school at Newcastle-upon-Tyne, in which he made such progress, that he was taken from thence and entered of Pembroke-hall, Cambridge. This was about the year 1518. In 1522 he was admitted to the degree of B.A.; and in 1524 he was elected a fellow of his college. In the following year he commenced M.A.; and having been ordained priest, he went, for farther improvement, to the Sorbonne at Paris; and from thence to Louvain; continuing on the continent till the year 1529. He had been brought up, and continued a zealous Papist; but on his return home, he applied with great diligence to the reading of the scriptures, as the safest guides in his theological studies. In 1533 Mr. Ridley was chosen senior proctor of the university; and while he continued in this office, the point of the pope's supremacy was brought before the university, to be examined upon the authority of scripture. No one was better qualified to give an opinion on this subject than Mr. Ridley; and after much public disputation, the university came to the following resolution: "That the bishop of Rome had no more authority and jurisdiction derived to him from God, in this kingdom of England, than any other foreign bishop;" and this was officially signed by Mr. Ridley, as well as by the vice-chancellor and the other proctor. In the year 1536, his well-known learning and talents procured him a powerful patron in archbishop Cranmer, who took him into his family, and made him his chaplain. He had, probably before this, abandoned the principles in which he had been educated; and being, in 1538, presented by the archbishop to the vicarage of Herne, in East Kent, he preached certain doctrines attached to the reformation, but nevertheless still adhered to the doctrine of transubstantiation. Among other converts whom he made to his own opinions was lady Fiennes, who proved a distinguished ornament to the cause which she adopted. To excite or enliven the devotion of his parishioners, he had the "Te Deum" sung in English, which was afterwards made the subject of an accusation against him. In 1539, when the act of the six articles was passed, he bore his testimony against it, though he himself was not likely to be affected by the penalties of the statute. In 1540 he went to Cambridge, and proceeded doctor in divinity; and soon after he was chosen to the mastership of Pembroke-hall. About the same time he was, through the influence of the archbishop, nominated chaplain to the king; and this honour was speedily followed by his collation to a prebendal stall in the cathedral church of Canterbury. In this city, when his duty called him to preach, he endeavoured with all his talents to expose to the people the abuses of Popery; which gave so much offence, that charges were exhibited against him for preaching contrary to the statute of the six articles. The attempt, however, of involving him in the penalties of the law, completely failed. Gardiner, bishop of Winchester, next endeavoured to entrap him; and articles were exhibited against him before the justices of the peace in Kent, and afterwards before the king and council, which charged him with preaching against auricular confession, and with directing the Te Deum to be sung in English. The accusation was fortunately referred to Cranmer, by the king, who immediately crushed it, much to the mortification of Dr. Ridley's enemies. About the year 1545 he he began to examine the doctrine of tranfubftantiation, which he and his friend and patron, Cranmer, rejected as unfcriptural. Towards the clofe of the year he was appointed prebend of St. Peter's, Weftminfter. It 1547 he was promoted to the bifhopric of Rochefter; and in the following year he was employed in reforming the liturgy, in conjunction with Cranmer, five other prelates, and fome learned divines; and in 1549 he was appointed one of the commiffioners empowered to fearch after all Anabaptifts, heretics, and contemners of the book of common prayer. In this character he was involved in the foul reproach of having contributed to bring to the ftake Joan Bocher, and others. (See CRANMER.) That he did this from confcientious motives, there can be no doubt; but he ought to have inveftigated the principles, before he proceeded to the horrid act of perfecution; and having a mind open to conviction, he would foon have found that no tenets, inculcated by the mild and holy Jefus, would lead to the infliction of corporal punifhment for the fake of curing mental error. He more than once oppofed the unreafonable commands and wifhes of thofe in power; and would no doubt, in the cafe of Bocher and others, have done fo too, had he felt it his duty.

The bifhop of Rochefter was one of the commiffioners appointed to fit in judgment on the caufe of Bonner, bifhop of London; and by him the fentence of deprivation was pronounced againft the prelate. This was in the reign of Edward. In that of Mary, as we fhall fee, ample revenge was taken of him. Ridley fucceeded to the bifhopric of London in the year 1549-50, when the bifhopric of Weftminfter was fuppreffed as a diftinct fee, and united to that of London. Ridley's conduct towards his predeceffor Bonner, and his family, after taking poffeffion of the epifcopal palace, was honourable to his integrity and benevolence, of which the following facts are fufficient proofs. He took care to preferve from injury the goods, &c. belonging to Bonner, allowing him full liberty to remove them when he pleafed. Such materials as Bonner had purchafed for the repair of his houfe and church, the new bifhop employed to the ufes for which they were defigned; but he repaid him the money which he had advanced for them. He took upon himfelf the difcharge of the fums which were due to Bonner's fervants for liveries and wages; and that the mother and fifter of that prelate, who lived near the palace at Fulham, and had their board there, might not be lofers in confequence of his promotion, he always fent for them to dinner and fupper, conftantly placing Mrs. Bonner at the head of the table, even when perfons of high rank were his guefts.

Soon after his tranflation to the fee of London, bifhop Ridley was nominated one of the commiffioners for examining Gardiner, bifhop of Winchefter, and concurred in his deprivation. In 1550 bifhop Ridley vifited his diocefe, and he directed that the altars fhould thenceforth be taken down in the churches, and tables fubftituted in their room, for the celebration of the Lord's fupper; to take away the falfe perfuafion which the people had, of facrifices to be offered upon altars. In 1551 the fweating ficknefs prevailed in London, and in the fpace of a few days carried off eight or nine hundred perfons; but in the midft of the alarm which this neceffarily occafioned, Ridley adminiftered in the duties of his office, trufting himfelf entirely to the good providence of God for fafety, in the danger to which he was every moment expofed; and he endeavoured, with all the zeal of an exemplary fpiritual paftor, to improve the public calamity to the reformation of the manners of the people. To promote more generally a reformation in the doctrine of the church, the council, this year, appointed Cranmer and Ridley to prepare a book of articles of faith. With this view they drew up forty-two articles, and fent copies of them to the other bifhops and learned divines, for their corrections and amendments; after which the archbifhop reviewed them a fecond time, and then prefented them to the council, where they received the royal fanction, and were publifhed by the king's authority, as an act of the fupremacy. In the year 1552 he paid a vifit to the princefs Mary, and offered to preach before her; but fhe refufed to hear him herfelf, or permit her fervants to attend to his doctrine; telling him, that, in her father's days, he would not have dared to have avouched that for God's word that he then did. Mary never forgot nor forgave this interference on the part of the prelate, which, notwithftanding the remarks of moft of Ridley's biographers, appears to us to have been uncalled for, if it were not even an act of rudenefs not eafily juftified.

When the parliament affembled in 1553, the king, who was languifhing under the decline which foon put an end to his life, ordered the two houfes to attend him at Whitehall, where bifhop Ridley preached before him, recommending with fuch energy the duties of beneficence and charity, that his majefty fent for him, to inquire how he could beft put in practice the duties which he had fo well and fo ftrongly enforced; and the refult of this fermon and conference was a determination in the king to found, or incorporate anew, and endow with ample revenues, thofe noble inftitutions, Chrift's, Bartholomew's, Bridewell, and St. Thomas's hofpitals.

Upon the death of Edward VI., Ridley was earneft in attempting to fet lady Jane Grey on the throne; but when the defign had mifcarried, he went to Mary to do her homage, and fubmit himfelf to her clemency. His reception was fuch as he might have expected: he was immediately committed to the Tower, where, however, he was treated with much lefs rigour than Cranmer and Latimer, who were likewife prifoners in the fame fortrefs. Ridley, it has been thought, might have recovered the queen's favour, if he would have brought the weight of his learning and authority to countenance her proceedings in religion. He was, however, too honeft to act againft his conviction; and he was, after eight months' imprifonment in the Tower, conveyed from thence to Oxford, where he was, on the 1ft of October 1555, condemned to death for herefy. During the fortnight between his condemnation and execution, the priefts tried all their means of perfuafion to gain him over to their caufe. He was deaf to their remonftrances, and was not to be fhaken in the principles which he had adopted.

The 15th of October being the day appointed by the court for his execution, he met the trial with calmnefs and fortitude. He called it his marriage-day, and fupped on the preceding evening with the utmoft cheerfulnefs, having invited fome friends on the occafion. When they rofe to depart, one of them offered to fit up with him through the night, which he would not permit, faying, he meant to go to bed, and, by God's will, to fleep as quietly that night as he ever had done in his life. On the following morning, having dreffed himfelf in his epifcopal habit, he walked to the place of execution, between the mayor and one of the aldermen of Oxford; and feeing Latimer approach, from whom he had been feparated fince their condemnation, he ran to meet him, and with a cheerful countenance embraced him, and exclaimed, "Be of good heart, brother, for God will either affuage the fury of the flames, or elfe give us ftrength to endure them." Then walking to the ftake, he kneeled down, kiffed it, and prayed with great fervour. A fermon was now preached, at the conclufion of which he was afked to recant; but he refufed, and with a fteadfaft voice cried out, "May God's will be done." He was then ftripped to his fhirt, and faftened by an iron chain to the fame ftake with bifhop Latimer. Every thing being ready, a kindled faggot was laid at Ridley's feet, who, when he faw the fire flaming up towards him, with a loud voice commended his foul to God. Latimer's fufferings were foon at an end, but Ridley endured the agonies of dying a much longer time, till they were terminated by the explofion of a bag of gunpowder, which had been fufpended from his neck: after this he difcovered no figns of life. Such was the end of bifhop Ridley, who was unqueftionably one of the moft eminent inftruments in promoting the caufe of the reformation. In private life he was a pattern of all the virtues. His temper was excellent; his manners very affable and agreeable; and of the benevolence of his heart he gave abundant proofs, in his extraordinary liberality to the poor. He was unqueftionably a man of great learning, and was author of a number of works. Many of his letters have been publifhed by Fox, in his "Acts and Monuments;" and may likewife be feen in Glofter's Life of Bifhop Ridley, to which, to Wood's Athen., and Neal's Hift. of the Puritans, our readers are referred.

Ridley, *Sir* Thomas, a learned civilian, of the fame family as the preceding, was born at Ely, and educated firft at Eton, and then at King's-college, Cambridge. He afterwards became a mafter in chancery, and vicar-general to the archbifhop of Canterbury. He died in 1628, and was author of "A View of Civil and Ecclefiaftical Law."

Ridley, Gloster, of the fame family with the preceding, was born in 1702, on board the Gloucefter Eaft Indiaman, whence he derived his name. He was educated in fchool-learning at Winchefter; from which place he was removed to New-college, Oxford, where he laid the foundation for thofe acquirements, by which he was afterwards diftinguifhed as a poet, hiftorian, and divine. He obtained fome preferment in the church; and in 1740 and 1742 he preached eight fermons at lady Moyer's lecture, which were publifhed. In 1763 he publifhed the "Life of Bifhop Ridley," to which we have referred; and fhortly after, "A Review of Philips's Life of Cardinal Pole." In reward for his labours in this controverfy, and in another which Mr. Archdeacon Blackburn's Confeffional produced, he was prefented by Secker to a golden prebend at Salifbury. He died in 1774, leaving a widow and four daughters, one of whom, Mrs. Evans, publifhed feveral novels. In the latter part of his life he loft two fons, young men of confiderable talents. The elder, James, was author of "The Tales of the Genii;" a humorous paper, called "The Schemer," afterwards collected into a volume; "The Hiftory of James Lovegrove," and feveral other literary pieces. Two poems by Dr. Ridley, one ftyled "Jovi Eleutherio, or an Offering to Liberty;" and the other entitled "Pfyche," were printed in Dodfley's Collection. "Melampus," the fequel of the latter, was printed by fubfcription. His tranfcript of the Syriac Gofpels was publifhed with a Latin tranflation, by profeffor White, in 2 vols. 4to. Gen. Biog.

Ridley, in *Geography*, a townfhip of America, in Delaware county, Pennfylvania, containing 991 inhabitants.

RIDOLLY, a town of Hindooftan, in the fubah of Agra; 35 miles S. of Agra.

RIDZIN. See Reussin.

RIE, in *Rural Economy*, a provincial term, applied to the operation of turning grain in a fieve, fo as to bring the *capes* into an eddy at the top. It is performed by a particular kind of circular motion.

RIEBACH, in *Geography*, a town of Germany, in the county of Hohenloe; 7 miles S.S.E. of Weichenfheim.

RIEBECK-CASTEEL, or the caftle of Van Riebeck, one of the divifions in the diftrict of Stellenbofch and Drakenftein, in the Cape diftrict, Southern Africa, which may be confidered as a prolongation of the *Paardeberg* (which fee), terminating to the northward in a high rocky fummit. It took its name from the founder of the colony having travelled to this diftance from the Cape, which is about 60 miles, and which, in that early period of the fettlement, was as far as it was confidered fafe to proceed, on account of the numerous natives, whofe race has now almoft difappeared from the face of the earth. The produce is the fame as that of Paardeberg, in both which there are as many corn-farms as freehold eftates.

RIEBEN, a town of Brandenburg, in the Middle Mark; 3 miles S. of Belitz.

RIECHENAU, a town of the country of the Grifons; 9 miles S.S.W. of Coire.

RIED, a town of Bavaria; 18 miles S. of Paffau.—Alfo, a town of Bavaria, in the principality of Aichftatt; 4 miles S.E. of Harrieden.

RIEDEN, a town of Germany, belonging to Anfpach, infulated in the principality of Culmbach; 22 miles N. of Anfpach.—Alfo, a town of Bavaria, in the Upper Palatinate; 9 miles S. of Amberg.

RIEDENBURG, a town of the bifhopric of Paffau, on the Inn; 12 miles S.S.W. of Paffau.—Alfo, a town of Bavaria, on the Altmuhl; 17 miles N.E. of Ingolftadt.

RIEDLIN, Vitus, in *Biography*, a diftinguifhed German phyfician, was born at Ulm in March, 1656, where many of his anceftors had practifed the fame profeffion with confiderable repute. He obtained his early education principally at his native city, and terminated his ftudies by going to Tuningen in 1674, where he made great acquifition, during a refidence of two years, and afterwards into Italy; and he graduated at Padua, about the end of the year 1676. He wifhed to have refided longer at this diftinguifhed univerfity; but his father having died in his boyhood, he was unable to procure the neceffary means, and therefore he returned to Ulm in the following year. In 1679 he was elected a member of the college of phyficians at Augfburg, where he fettled, and obtained a confiderable fhare of practice among the firft people; but on the preffing folicitations of his countrymen, he returned to Ulm in 1704, and remained there, in the enjoyment of extenfive reputation, till his death, which took place in 1724. His principal work is entitled "Lineæ Medicæ, continentes Obfervationes, Hiftorias, Experimenta, Cauteles, &c. à Menfe Januario 1695 ad Menfem Junium 1700," in ten fmall volumes. It is a fort of journal, in which he not only recorded his own obfervations, but thofe of others. It does not, however, commend itfelf by much originality or good method. Eloy Dict. Hift.

RIEDLINGEN, in *Geography*, a town of Wurtemberg; 27 miles S.W. of Ulm. N. lat. 48° 11′. E. long. 9° 30′.

RIEFF. See Riva.

RIEGEL, Henry Joseph, in *Biography*, a mufician born at Wertheim, in Franconia, in 1741. M. Laborde does him the honour to call him a French compofer. He ftudied mufic under Jomelli, at Stutgard, and was recommended by Richter to complete the mufical education of a young lady of rank in France; which having finifhed, he eftablifhed himfelf at Paris in 1765. His paffion for the harpſichord confined his ſtudies chiefly to that inſtrument for a conſiderable time; but after having acquired a diſtinguiſhed reputation for his execution, he attended ſcholars, and applied to compoſition. Beſides many quartets, concertos, ſonatas, duos, &c. he compoſed ſymphonies à grand orcheſtra, which had conſiderable ſucceſs at the concert of amateurs. He gained reputation by a French oratorio, "The Flight from Egypt," the firſt work of that kind that was executed at the Concert Spirituel, where it was well received for four ſucceſſive years. A ſecond oratorio, "The Taking of Jericho," had likewiſe merited applauſe.

His comic opera, "The Cobler and Financier," was at firſt repreſented at court, but afterwards well received in the capital, at the Italian theatre, though not performed by the beſt actors.

What characterizes his compoſitions is the great purity of his harmony. His effects are ingenious: in his capital pieces of ſymphonic compoſition, there is always a natural and regular melody. This compoſer, paſſionate for his art, enjoyed, free from envy, the talents of others. An enemy to cabal, he was excluſively attached to no kind of ſtyle; but enjoying whatever was good in all ſtyles, (French, Italian, German,) he was one of the few foreigners who did the moſt honour to the profeſſion in France. Laborde.

RIEHEN, in *Geography*, a town of Switzerland, in the biſhopric of Bâle, and principal place of a bailiwic; 3 miles E. of Bâle.

RIELVES, a town of Spain, in New Caſtile; 11 miles N.W. of Toledo.

RIEMLING, in *Ichthyology*, a name given by ſeveral to the ſmall freſh-water fiſh, called by the Latins *poxinus*, and vulgarly the *pink*.

RIENECK, in *Geography*, a town and citadel of Germany, and capital of a county of the ſame name, on the Sinn; 36 miles E. of Frankfort on the Maine. N. lat. 50° 11′. E. long. 9° 47′.

RIENS ARREAR, in *Law*, a kind of plea uſed to an action of debt upon arrearages of accounts; by which the defendant alleges, that there is nothing in arrear.

RIENS *paſſe par le fait, nothing paſſes by the deed*, is the form of an exception taken in ſome caſes to an action.

RIENS *par deſcent, nothing by deſcent*, is the plea of an heir, when ſued for his anceſtor's debt, though he had no lands from it by deſcent, nor has aſſets in hand.

RIENTZ, in *Geography*, a river of the county of Tyrol, which joins the Eyſach, at Brixen.

RIENZI, in *Biography*. See GABRINI.

RIER, or REER-COUNTY, *Retro-comitatus*, in *Law*, is uſed in the ſtatute of Weſtm. 2. c. 39. 2 Edw. III. cap. 5. and in our law-books, in oppoſition to *open county*.

This appears to be ſome public place, which the ſheriff appoints for the receipt of the king's money, after the end of the county-court. Fleta ſays it is *dies craſtinus poſt comitatum*.

RIERSDORFF, in *Geography*, a town of Auſtria; 3 miles W. of Mauttern.

RIESENBURG, a town of Pruſſia, in the province of Oberland; 18 miles S.W. of Konigſberg. N. lat. 53° 43′. E. long. 19° 24′.

RIESENKOPPE, or SCHNEE, a mountain of Sileſia, and one of the moſt elevated in Europe, in the principality of Jauer.

RIESSA, a town of Saxony, in the margraviate of Meiſſen, on the Elbe; 12 miles N.W. of Meiſſen. N. lat. 51° 18′. E. long. 13° 15′.

RIETBERG, a town of Germany, and capital of a county of the ſame name, on the Embs, which county is about 18 miles long and 6 broad; 12 miles W.N.W. of Paderborn. N. lat. 51° 55′. E. long. 18° 32′.

RIETI, a town of Italy, in the duchy of Spoleto, the ſee of a biſhop; containing, beſides the cathedral, three collegiate and ſix pariſh churches, and 12 convents. In the year 1785, it was much damaged by an earthquake; 25 miles E.S.E. of Spoleto. N. lat. 42° 44′. E. long. 12° 56′.

RIEV VOLODIMEROV, a town of Ruſſia, in the government of Tver; 64 miles S.W. of Tver. N. lat. 56° 5′. E. long. 34° 44′.

RIEUMS, a town of France, in the department of the Upper Garonne, and chief place of a canton, in the diſtrict of Murat; 9 miles S.W. of Murat. The place contains 1425, and the canton 6316 inhabitants, on a territory of 200 kiliometres, in 15 communes.

RIEUPEIROUX, a town of France, in the department of the Aveiron, and chief place of a canton, in the diſtrict of Villefranche; 15 miles W. of Rodes. The place contains 1752, and the canton 6299 inhabitants, on a territory of 182½ kiliometres, in 13 communes.

RIEUX, a town of France, and principal place of a diſtrict, in the department of the Upper Garonne; and before the revolution, the ſee of a biſhop; 24 miles S. of Toulouſe. N. lat. 43° 15′. E. long. 1° 17′.—Alſo, a town of France, in the department of the Morbihan; 10 miles S.E. of Rochefort.—Alſo, a town in the department of the Ille and Vilaine, on the Vilaine; 6 miles S. of Redon.—Alſo, a town in the department of the Aube; 10 miles E. of Carcaſſonne.

RIEZ, an old, populous town of France, formerly Civitas Reienſium, a biſhop's ſee, and the ſeat of a council in 439, ſituated on a plain between the Aſſe and Verdun, in the department of the Lower Alps, and chief place of a canton, in the diſtrict of Digne; 18 miles S. of Digne. The place contains 2784, and the canton 9963 inhabitants, on a territory of 330 kiliometres, in 14 communes. Its environs abound in wine and fruits.

RIEZE, a river of France, which runs into the Garonne, near Saverdun.

RIF, one of the largeſt provinces of the empire of Morocco, ſituate in that chain of mountains which forms a part of the Leſſer Atlas. This province, the ſoil of which is ſtony, is bounded by that of Garet to the eaſt, the Mediterranean to the north, on the coaſt of which is the ancient city of Gomera, and alſo Melilla and Veles de Pegnon, belonging to Spain; by the province of Garb to the weſt, and to the ſouth by thoſe of Shaus or Chaus, and Fez.

RIF. See BAHIRA.

RIF-DYKE, one of the ſmaller Orkney iſlands, eaſt of North Ronaldſha. N. lat. 59° 13′. W. long. 2° 17′.

RIFENBACH, a river of Germany, which runs into the Inn, 2 miles N. of Kufſtain.

RIFFREDO, a town of Etruria; 20 miles N.N.E. of Florence.

RIFLE GUNS, in the *Military Art*, are thoſe whoſe barrels, inſtead of being ſmooth on the inſide, like our common pieces, are formed with a number of ſpiral channels, reſembling female ſcrews; except only that the threads or rifles are leſs deflected, making only one turn, or a little more, in the whole length of the piece. This conſtruction of the barrel is employed for correcting the irregularity in the flight of balls from ſmooth barrels, of which we have mentioned ſeveral inſtances under our articles GUNNERY and PROJECTILES. It has, for inſtance, been found, from the experiments of Mr. Robins, that notwithſtanding the piece was firmly fixed, and fired with the ſame weight of powder,

powder, ſometimes the ball was deflected to the right, ſometimes to the left; ſometimes above, and at others below, the true line of direction. It has alſo been obſerved, that the degree of deflection increaſes in a much greater proportion than the diſtance of the object fired at: thus, at double the diſtance, the deflection of the ball from the line in which the piece is pointed is conſiderably more than double, and at treble the diſtance more than treble, what it was at firſt. Mr. Robins ſecured a muſket barrel upon a block of wood, and firing it with a ball at a board of a foot ſquare, at 60 yards diſtance, found that it miſſed the board only once in 16 ſucceſſive diſcharges; yet when fired with a ſmaller charge, at the diſtance of 760 yards, the ball was thrown ſometimes 100 yards to the right or left of the line in which it was pointed. The direction upwards and downwards was alſo found equally uncertain; the ball, in ſome diſcharges, having ſtruck the ground 200 yards nearer the piece than it did at others.

It is not difficult to account for theſe irregularities: they doubtleſs proceed from the impoſſibility of fitting a ball ſo accurately to any plain piece, but that it will rub more againſt one ſide of the barrel than another, in its paſſage through it. Whatever ſide, therefore, of the muzzle the ball is laſt in contact with, on quitting the piece, it will acquire a whirling motion towards that ſide, and will be found to bend the line of its flight in the ſame direction, whether it be upwards or downwards, to the right or left; or obliquely, partaking in ſome degree of both; and after quitting the barrel, this deflection, which, though in the firſt inſtance it is but trifling and inconſiderable, is ſtill farther increaſed by the reſiſtance of the air; this being greateſt on that ſide where the whirling motion conſpires with the progreſſive one, and leaſt on that ſide where it is oppoſed to it. Thus, if the ball, in its paſſage out, rubs againſt the left ſide of the barrel, it will whirl towards that ſide; and as the right ſide of the ball will, therefore, turn up againſt the air during its flight, the reſiſtance of the air will become greateſt on the right ſide, and the ball be forced away to the left, which was the direction it whirled in. If the axis, about which the rotatory motion of the ball is made, preſerved its poſition during the whole flight, the deflection would be in the ſame direction from one end of the track to the other; though it is obvious, that the quantity of this deflection would ſtill not be proportional to the diſtance: for if all reſiſtance of the ball were to ceaſe at any part of its flight, ſtill the ball would neceſſarily purſue the line in which it then moved, and the deflection be double at a double diſtance, treble at a treble diſtance, and ſo on. But as this reſiſtance does not ceaſe, but continue to act upon the ball throughout its whole flight, (though leſs in the latter part of it than at the commencement, in conſequence of the decreaſe of velocity,) it is obvious that the deflection of the ball will be accelerated at every inſtant, and conſequently increaſe in a greater proportion than the diſtance; as we have ſeen it has been found to do, from the experiments above alluded to. It happens, however, from various accidental circumſtances, that the axis of the ball's rotation frequently changes its poſition ſeveral times during the flight; ſo that the ball, inſtead of bending its courſe uniformly in the ſame direction, often deſcribes a track variouſly contorted. So great, however, is the tendency of the ball to deflect itſelf againſt the ſide it rubs againſt, that it has been ſaid, though we never ſaw the experiments authenticated, that a ball, when fired out of a barrel bent towards the left hand, (and which will, therefore, be thrown from the piece in the direction of the bend,) yet as the ball, in this caſe, will be forced to rub againſt the right ſide of the muzzle, and thus turn its left ſide up againſt the air, ſo it will be found to alter its courſe during the flight, and bend towards the right hand, ſo as to fall a conſiderable way to the right hand of the line in which the piece was pointed.

It will readily appear, therefore, from what has been ſtated, that theſe variations will be more frequent and conſiderable when the ball runs very looſe in the piece; or when, from any roughneſs on its ſurface, or on the middle of the barrel, a conſiderable degree of friction takes place between them. With a view to prevent friction, it has been propoſed to greaſe the ball; but this we ſhould imagine would be of very little ſervice. All that can be done in a plain barrel is to have the balls caſt very ſolid and true, and afterwards milled in the ſame manner as is now practiſed upon ſhot: the barrel alſo ſhould be very ſmooth on the inſide, and the ball fit it very accurately, ſo as to leave ſcarcely any windage: yet, with all theſe precautions, it is very difficult, we may ſay impoſſible, to prevent it entirely; for gravity will conſtantly act, and friction on the under ſide will naturally be occaſioned by the weight of the ball. In fact, when we conſider the cauſes of the aberration in the flight of balls, it will be pretty evident that the only means of correcting it is by preventing the ball from rubbing more againſt one ſide of the barrel than another in paſſing through it; and by giving to the bullet a motion which will counteract every accidental one, and preſerve its direction, by making the reſiſtance of the air upon the fore part continue the ſame during its whole flight; that is, by giving it a rotatory motion perpendicular to the line of direction. The contrivance for this purpoſe is called rifling, and conſiſts of forming upon the inſide of the barrels a number of threads and furrows, either in a ſtraight or ſpiral direction, into which the ball is moulded, whereby any rolling motion along the ſides of the barrel is effectually prevented.

The numbers of theſe threads in a gun are different, according to the fancy of the workman and the ſize of the barrel; and, in like manner, the depth to which theſe channels or rifles are cut down, is not regulated by any invariable rule; but differs according to the country where the work is performed, or the caprice of the artificer. There are alſo different methods of charging pieces of this kind, but the uſual one is as follows: after the powder is put in, a leaden bullet, ſomewhat larger than the bore of the gun, is taken, and having greaſed it well, it is laid on the mouth of the piece, and rammed down with an iron rammer, hollow at the end; the ſoftneſs of the lead giving way to the violence with which the bullet is impelled, that zone of the bullet which is contiguous to the piece, varies its circular form, and acquires the ſhape of the inſide of the barrel, ſo that it becomes the part of a male ſcrew, exactly fitting the indents of the rifle. And hence it happens that, when the piece is fired, the indented zone of the bullet follows the ſweep of the rifles, and thereby, beſides its progreſſive motion, acquires a circular one round the axis of the barrel, which motion will be continued to the bullet after its ſeparation from the piece; by which means a bullet diſcharged from a rifled barrel is conſtantly made to whirl round an axis, which is coincident with the line of its flight. And hence it follows, that the reſiſtance on the foremoſt ſurface of the bullet is equally diſtributed round the pole of its circular motion, and acts with an equal effort on every ſide of the line of direction, ſo that this reſiſtance can produce no deviation from that line: and if, by the caſual irregularity of the foremoſt ſurface of the bullet, or by any other accident, the reſiſtance ſhould be ſtronger on one ſide of

the

the pole of the circular motion than on the other; yet, as the place where this greater resistance acts must perpetually shift its position round the line, in which the bullet flies, the deflection, which this inequality would occasion, if it acted constantly with the same given tendency, is now continually rectified by the various and contrary tendencies of that disturbing force, during the course of one revolution; so that the ball will always go right forwards, and thus that deflection or deviation, already taken notice of under the article PROJECTILE, and in the preceding part of this article, will be prevented. This may be explained by the motion of an arrow; for if an arrow that is not feathered be shot from a bow, its motion will be very irregular; but when the feathers of the arrow are properly arranged in a spiral form, so as to make the arrow spin round its axis, it will always fly straight forward. Upon the same principle, every school-boy finds himself under the necessity of making his shuttle-cock spin, before he can depend upon the truth of its flight. Mr. Robins observes, that the actual motions of bullets discharged from rifled pieces correspond very well with these speculations. Although the use of pieces of this kind had long prevailed in Europe, particularly in Germany and Switzerland, the advantages resulting from them have been very imperfectly understood, and, as Mr. Robins observes, unaccountably misrepresented. The three following reasons have been constantly alleged in favour of this construction: either that the inflammation of the powder was greater by the resistance which the bullet thus forced into the barrel gave it, and that by it the bullet received a much greater impulsion than it would have done from the same quantity of powder in a common piece, or that the bullet, by the compounding of its circular and revolving motion, did, as it were, bore the air, and thereby flew to a much greater distance, than it would otherwise have done; or that, by the same boring motion, it made its way much easier through all solid substances, and penetrated much deeper into them, than if discharged in the common manner. But the ingenious writer just mentioned, satisfied himself by numerous experiments made with rifled barrels of various sizes, that none of these reasons hold true in the use of such pieces; but that the advantage of their construction results from its preventing the deflection of the ball, as we have above represented it. And that it produced this effect he found by observing, that the same hemisphere of the bullet which lies foremost in the piece, continued foremost during the whole course of its flight.

In Germany and Switzerland, an improvement is made in the method, already recited, of charging these pieces; especially those of the larger sort, which are used for shooting at great distances. This is done by cutting a piece of very thin leather, or of thin fustian, in a circular shape, somewhat larger than the bore of the barrel. This circular piece being greased on one side is laid upon the muzzle with its greasy parts downwards, and the bullet being placed upon it, is then forced down the barrel with it; by which means the leather or fustian incloses the lower half of the bullet, and by its interposition between the bullet and the rifles, prevents the lead from being cut by them. But in those barrels where this method is practised, the rifles are generally shallow, and the bullet ought not to be too large. The rifle-barrels, which have been made in England, where they are not very common, are contrived to be charged at the breech, the piece being, for this purpose, made larger there than in any other part. The powder and bullet are put in through the side of the barrel by an opening, which, when the piece is loaded, is filled up with a screw. By this means, when the piece is fired, the bullet is forced through the rifles, and acquires the same spiral motion as in the former kind of pieces; other barrels unscrew at the breech, for the convenience of charging them. With regard to the defects of these rifled pieces, Mr. Robins observes, that if either the angle of elevation, or the curvature of the bullet's track through the air be great, the inclination of the axis round which it whirls will cause irregularities, which will often produce considerable deflections. Accordingly he proposes to make use of bullets of an egg-like form, instead of spherical ones, and to fire them with their broad ends foremost, that thus their longer axes may be always carried, by their centres of gravity, into the lines of their flight. Upon the whole, he concludes, that whatever tends to diminish the friction of these pieces, tends, at the same time, to render them more complete; and consequently the less the rifles are indented, the better they are, provided that they are just sufficient to keep the bullet from turning round in the piece. Besides, the bullet ought to be no larger than to be just pressed by the rifles, for the easier the bullet moves in the piece, supposing it not to shift its position, the more violent and accurate its flight will be. And to render them in this respect still more complete, the sweep of the rifles should be in each part exactly parallel to each other: for then, after the bullet is once put in motion, it will slide out of the barrel without any shake, and with a much smaller degree of friction than if the threads of the rifles have not all of them the same degree of incurvation. The foreigners are so exact in this respect, that they try their pieces, with a view to this particular, in the following manner: they first pour melted lead into them, and letting it cool, they procure a leaden cylinder of perhaps two or three diameters in length, exactly fitted to one part of the inside of the piece; then if this leaden cylinder, being gently pushed by the rammer, will pass from one end of the barrel to the other, without any sensible strain or effort, they pronounce the piece perfect; but if it any where sticks or moves hard they esteem it defective.

We have stated that some rifle-pieces are charged at the breech; these, however, are necessarily much dearer than the others, and excepting the expedition in charging them, are really inferior to those in which the ball is introduced at the muzzle, on which account they are not much employed at present, at least not in this country. The want of expedition in the charging pieces of this kind is, however, a very serious defect, to remedy which, it has been proposed to have the balls cast with projections upon them, in the same manner as described in the following article on RIFLE *Ordnance*. This may be done with great ease and accuracy, by making corresponding hollows round the zone of the bullet-mould; by this means the balls may be fitted so accurately to the rifles, as to leave scarcely any windage; while the friction will be less than it is either when the ball is put in at the breech, or forced in at the muzzle.

In treating of the causes of aberration in the flight of balls, we have supposed the air to be perfectly at rest; but it is evident that the force of the wind will affect balls considerably, whether they are fired from a plain or a rifle barrel; this effect, however, will be much less in the latter than in the former; but in neither case is it possible either to avoid it entirely, or to estimate the quantity of aberration that it may, under different circumstances, occasion.

Pieces intended for shooting with ball, whether they be plain or rifled, ought to be of much more equal thick-

nefs

nefs from the breech to the muzzle, than thofe that are intended for fhot only. In every barrel there is an undulating vibration communicated to the metal by the explofion. This is moft remarkable in a thin barrel, and when the charge is great, and in an equal degree, whether the piece be rifle or plain, and therefore ought to be equally attended to by gunfmiths in both cafes. For more on the fubject of rifle mufket barrels, fee Robins' Tracts, vol. i. p. 328, &c.; fee alfo Nicholfon's Philofophical Journal, vol. i. p. 382; and for rifle ordnance, fee the Memoir of the National Inftitute mentioned in the following article.

RIFLE *Ordnance*. After the important advantages attending rifled barrel mufkets were well underftood, the idea naturally occurred of carrying the fame improvements into cannons and field-pieces, and many experiments have been made with a view of conftructing thefe on fimilar principles to the mufket. The firft attempt of this kind was made by Dr. Lind, and Capt. Alexander Blair, of the 69th regiment, in 1774. The pieces are of caft iron, and are not bored like the common cannon, but have the rifles moulded on their core, after which they are cleaned out, and furnifhed with the proper inftruments.

Guns of this defcription, which are intended for the field, ought never to be made to carry a ball of above one or two pounds weight at moft; a leaden bullet of that weight being fufficient to deftroy either man or horfe. A pound gun of this defcription, of good metal, need not weigh above an hundred weight, and its carriage about another hundred, and may therefore be eafily tranfported from place to place by a few men, and a couple of good horfes may tranfport fix of thefe guns and their carriages, if put into a cart. But for other purpofes, in which a greater momentum is neceffary, there is nothing to prevent them being made of the ufual calibre.

The following are the dimenfions that have been recommended for thefe kinds of cannon. The length of the gun being divided into feven equal parts, the length of the firft reinforce is two of thefe parts; the fecond reinforce $1\frac{15}{16}$ of the diameter of the calibre; the chafe $3\frac{1}{16}$ diameter of the calibre. The diftance of the hind part of the bafe ring to the beginning of the bore is $1\frac{3}{16}$ calibre. The trunnions are each one calibre in length, and the fame in breadth; their centres are placed $\frac{3}{7}$ths of the length of the gun from the hind part of the bafe ring, in fuch a manner, that the axis of the trunnions pafs through the centre line of the bore, which prevents the gun from kicking, and breaking its carriage. The length of the cafcable is $1\frac{3}{16}$ of a calibre.

The calibre of the gun being divided into 16 equal parts; then

The thicknefs of metal from the bafe ring to the bore, is - - - - - - -	18.5
At the end of the firft reinforce - -	17
At the fame place for the beginning of the fecond reinforce - - - - - -	17
At the end of the fecond reinforce - -	15
At the fame place for the beginning of the chafe	13.75
At the end of the chafe, or muzzle, the mouldings excluded - - - - - -	9
At the fwelling of the muzzle - -	12
At the muzzle fillet - - - -	9.5

Diameter of its neck - - - -	10.5

The vent fhould be placed about half an inch from the bottom of the chamber or bore, that the cartridge may be pricked, left fome of the bottom of the cartridges fhould be left when the gun is fponged, which might retard the firing till the ball be again drawn, which is very difficult in pieces of this kind.

The rifles in this gun make one fpiral turn in the length of the bore, but go no nearer to the breech, in their full fize, than two calibres, and terminate in a gentle flope in half a calibre more, fo as not to prevent the cartridge, with the powder, from being eafily fent home to the bottom of the gun, which would otherwife conftantly happen with the flannel cartridges, and even fometimes with paper ones, if not made to enter very loofely. The fhape of the rifles is femicircular, their breadth being equal to the diameter, which is $\frac{3}{16}$ths of the calibre, and their depth $\frac{6}{16}$ths of a calibre. The bullets are of lead, having fix knobs caft on them, to fit the rifles of the gun; and being thus made of foft metal, they do not injure the rifles.

Rifle ordnance, however, of any calibre, might be made to carry iron fhot for battering, or for other purpofes; provided holes, that are a little wider at their bottoms than at their upper parts, be caft in a zone round the ball, for receiving afterwards leaden knobs to fit the rifles of the cannon; by which means the iron fhot will have its intended line of direction preferved, without injuring the rifles more than if the whole ball was of lead, the rotatory motion round its axis, or the line of its direction, which corrects the aberration, being communicated to it by the leaden knobs following the fpiral turn of the rifles in their progrefs out of the gun. It is particularly to be obferved, that the balls muft be made to go eafily down into the piece, fo that the cartridge with the powder, and the bullet, may be both fent home together with a fingle pufh of the hand, without any wadding above either the powder or the ball, by which means the gun is quickly loaded, and the ball flies farther than when it is forcibly driven into the gun, as was found from many experiments. The only reafon why, in common rifle mufkets, the bullets are forcibly rammed in, is, that the zone of the ball which is contiguous to the infide of the bore, may have the figure of the rifles impreffed upon it, in fuch a manner, as to become part of a male fcrew, exactly fitting the indents of the rifle, which is not at all neceffary in the prefent cafe, the figure of the rifles being, in the firft inftance, caft upon the ball. Thefe knobs retard the flight of the ball in fome degree, but this fmall difadvantage is fully counterbalanced by the eafe with which the gun is loaded, its fervice being nearly as quick as that of a common field-piece, and the retardation and quantity of the whirling motion which is communicated to the bullet being conftantly the fame, it will not in the leaft affect the experiments

ments made with them, in order to determine the reſiſtance of the air.

The French, in the courſe of the late war, have made experiments on rifle ordnance of a different kind to that above explained; in which, in fact, the gun is of the uſual form, the principal difference being in the nature and form of the ball, which M. Guyton (who has given an account of theſe experiments in vol. vii. of the National Inſtitute of France) calls *bullets a bague de plomb*, which in form are cylindrico-ſpherical, the cylindric part being next the charge. A rim of lead is fixed round the centre of the ball, rather exceeding the bore of the gun, which is cut off by the edge of the muzzle, in introducing the ball into the piece, whereby all the advantages of the rifle are obtained, although the rotatory motion above deſcribed, and which is ſuppoſed to have ſo great an influence on the direction, has not place in the preſent inſtance. According to M. Guyton's report, the accuracy in the rectilinear motion of theſe balls exceeded any thing before known in artillery practice; beſides, that although the weight of the bullet was nearly double that of a common ſhot of a piece of the ſame calibre, the range in very few inſtances fell ſhort of the common range, and in ſome even conſiderably exceeded it. The difficulty and time requiſite in loading a gun with a ball of this kind, however, are ſo great, as, in our opinion, to render it uſeleſs, although it ſeems to have been recommended for adoption, in a few particular ſituations, by a committee of French artillery officers. In the courſe of the memoir in which the above experiments are detailed, M. Guyton mentions another kind of rifle cannon, invented by an Italian officer, which was found remarkably correct in projecting the ball in a right line. The bore of this gun is ſlightly conical, being greateſt at the breech, where the piece is loaded by unſcrewing the breech, as in ſome rifle muſkets and piſtols: the ball is of lead, which muſt neceſſarily, from the conſtruction of the gun, change its form in paſſing through the bore. But this, as well as the one above-mentioned, ſeem to require too much time in loading to be ever adopted as regular pieces of ordnance.

RIFTS, in *Farriery*, are ſmall cracks, clefts, chaps, or any other ſimilar fiſſures or openings in the hoofs of horſes' feet. See thoſe heads.

RIG. See RIDGLING.

RIG, in *Rural Economy*, a male ſheep, with none, or one teſticle only in the ſcrotum.

RIGA, in *Geography*, a ſea-port town of Ruſſia, formerly the capital of Livonia, now of the government of its own name, is ſituated in the gulf of Riga, and the ſee of an archbiſhop. This town derives its conſequence from its ſituation on the Duna, which, being navigable from the frontiers of the government of Polotſk, brings the productions of the north-eaſtern parts of Poland and the weſtern provinces of Ruſſia, and has depth enough to receive, cloſe to its walls, ſhips of burden, which ſail to and from the Baltic. Next to St. Peterſburg, it is the moſt commercial town in the Ruſſian empire. The trade is chiefly carried on by foreign merchants, who reſide in the town. Thoſe of the Engliſh factory poſſeſs the greateſt ſhare of the commerce, and live in an hoſpitable, ſplendid manner. The principal exports are corn, hemp, flax, iron, timber, maſts, leather, tallow; and the imports are ſalt, cloth, ſilks, wine, grocery, potaſh, and ſalted herrings. The maſt trade is peculiarly beneficial to the town; the burghers of Riga ſend perſons, who are called maſt-cutters, into the Ruſſian provinces, to mark the trees, which are purchaſed ſtanding. They grow moſtly on the diſtricts which border the Dnieper, are ſent up that river to a landing-place, tranſported 30 verſts to the Duna, are then formed into floats of from 50 to 200 pieces, and deſcend the ſtream to Riga. The tree which produces the largeſt maſts is the Scotch fir. Thoſe pieces which are from 18 to 25 inches in diameter, are called maſts; under thoſe dimenſions, ſpars, or, in England, Norway maſts; becauſe Norway exports no trees more than 18 inches in diameter. The Engliſh merchants, who contract with government, buy the maſts from the burghers of Riga, which are ſkilfully examined in order to aſcertain their ſoundneſs, and are uſually from 70 to 80 feet in length.

The hemp is brought from the Ukraine and Poland, and requires two years in its paſſage to Riga. The barks in which it is conveyed are from 250 to 300 tons burden, are covered with mats, ſloping like a pent-houſe roof, and have a falſe bottom. They aſcend the Dnieper and Duna; but on account of numerous ſhoals, can only paſs the Duna in the ſpring, or about three weeks after the ſnow begins to melt, and if they miſs that time, they are delayed till autumn. The hemp exported from Riga is generally more eſteemed, and 30 *per cent.* dearer than that exported from Peterſburg; the former comes from the Ukraine, the provinces of Mohile and Polotſk, and the neighbouring parts of Poland; the other from the governments of Tver and Novogorod. The Riga hemp is chiefly uſed for ſhrouds and ſtays of men of war, and procured by contract for the Engliſh admiralty and the Eaſt India company.

The inhabitants of Riga carry on alſo a conſiderable commerce in ſalt. They import it from Spain, and ſend it up the Duna, to ſupply the diſtricts bordering on that river; and by land into Courland, and into the neighbouring provinces of Poland. This town, ſays Mr. Coxe, contains within the fortifications 9000 inhabitants, and in the ſuburbs 15,000, excluſive of a garriſon of 1000 ſoldiers. According to Heym, the town and ſuburbs contain 14,280 males, and 13,516 females.

Over the Duna at Riga is a floating wooden bridge, 40 feet in breadth, and 2600 in length. A row of piles extends from one ſhore to the other; each pile is from 25 to 40 feet long, according to the depth of the river, and appears about four feet above the level of the water. To theſe piles the ponts of the bridge are looſely faſtened, by means of iron chains fixed to the tranſverſe beams. The bridge riſes and falls with the river; and, under the wheels of heavy-laden carriages, plays as if actuated by a ſpring. This is the faſhionable walk, and is an agreeable buſy ſcene, when crowded with people, and lined on each ſide with ſhips taking in or unloading their cargoes. In the beginning of winter, when the froſt ſets in, the bridge is removed; the piles, remaining in the water, are forced up by the ice, and conveyed to land; and the whole is laid down again in the ſpring.

Riga was built in the year 1200, and ſoon after incloſed by a wall. At different periods it hath ſuffered much by fires and ſieges. N. lat. 56° 55′. E. long. 23° 54′.

RIGA, Ital., a line of the ſtaff, in *Muſic*; and ſpeaking of muſic in general, the whole five lines, or ſtaff, are called *una riga*.

RIGADON, RIGODON, and *Rigaudon*, a gay and lively dance, written all theſe ſeveral ways. Some ſay it came from Provence; but Rouſſeau affirms, that he has been told by an old dancing-maſter, that it had its name from its inventor, Rigaud.

At the beginning of the laſt century, there were three dances which every eminent maſter taught, and every nobleman's man's and gentleman's child learned, in the courfe of their education: thefe were the minuet, rigaudon, and l'ouvre, all natives of France, during the reign of Louis XIV.

The air to the rigaudon is always in jig time of $\frac{6}{8}$, beginning with an odd quaver. See DANCE, MINUET, and L'OUVRE.

RIGAL, in *Mufic*. See RIGOLL.

RIGAUD, HYACINTH, in *Biography*, was born at Perpignan, in Languedoc, in 1663, and was the fon of Matthias Rigaud, a painter of fome note, from whom, of courfe, he received his initiation into the myfteries of his art. He had the misfortune to lofe his inftructor, when he was only eight years of age; and for a while, he was at the mercy of incapable mafters. At length he became acquainted with a portrait-painter, of the name of Ranc, under whom he acquired confiderable freedom of tafte; and, after a few years, was enabled to produce works which rivalled thofe of his mafter, for truth, for livelinefs, and expreffion.

He was impatiently defirous of vifiting Italy, but was diffuaded from it by Le Brun, who advifed him to continue at Paris, and ftudy portraiture; by which he might affure himfelf of fortune and reputation: and his fubfequent fuccefs proved the propriety and kindnefs of the advice. He foon diftinguifhed himfelf by a richnefs and boldnefs of ftyle, that induced the king of France, Louis XIV., to fit to him for his portrait; and in fucceffion, he painted the princes of the blood, and prime nobility of the kingdom. Many foreign princes, nobles, and generals, alfo had their portraits from his hand; and he treated them with a fplendour in compofition, of which he is the inventor, and which unfortunately governed the French fchool of portrait-painters till the revolution. We fay, unfortunately!—for though Rigaud managed it with great dexterity, yet not being founded in nature, it neceffarily led to error. To produce fuperior grace, the actions of the figures are twifted, and too often diftorted: they are engaged about trifles, with an air of immenfe importance; and the draperies arranged in flowing lines, which convey an idea of motion in fubftances which would require a guft of wind to move them, while the wearers are tranquilly feated in fplendid apartments, and under complete fhelter. He died in 1743, at the advanced age of 80.

RIGAULT, NICHOLAS, was born at Paris in 1577, and was educated among the Jefuits, who in vain attempted to induce him to enter into their fociety. As a literary character, he made himfelf known by a fatirical work, entitled "Funus Parafiticum," publifhed in 1596; with which the celebrated de Thou was fo much delighted, that he entrufted him with the education of his fon. When the learned Cafaubon, who had the care of the royal library, removed to England, Rigault fucceeded him in that employment. His fervices were fo well approved, that he was created attorney-general of the fovereign chamber of Nanci, counfellor to the parliament of Metz, and, finally, intendant of that province. He died at Toul in 1654, at the age of 77, with a character for generofity, modefty, and benevolence, that contributed as much to his reputation as his numerous writings. It was chiefly as an editor of Greek and Latin authors that he made himfelf known to the learned world. Of thefe were "Minutius Felix," 1643; "St. Cyprian," 1648; and "Tertullian," 1664; enriched with ufeful notes, corrections, and obfervations. He gave tranflations of the Greek writers, "Onofander," "Artemidorus," and others; and he edited, with notes, "Phædrus," "Martial," "Rei Agrariæ Scriptores," &c. He alfo wrote and edited fome works on juridical fubjects; and he was appointed, together with Peter Dupin, by the will of the prefident de Thou, to give a complete edition of his hiftory, which appeared at Geneva in 1620.

RIGEL, in *Aftronomy* See REGEL.

RIGEL, or RIEGEL, ANTHONY, in *Biography*, a harpfichord mafter and compofer. In 1780 he was at Spire, Manheim, and Paris, where he publifhed pieces for the harpfichord, with a violin accompaniment in duo, *a parte equali;* and afterwards capriccios for the harpfichord. His ftyle is flight, with little invention, but not vulgar.

RIGG, in *Agriculture*, a provincial word, ufed to fignify the fame as ridge.

RIGGEN, in *Rural Economy*, the ridge of the roof of a building. See FARM-*Building*.

RIGGEN-*Tree*, the piece of timber laid along the ridge of a roof, to fupport the heads of the fpars or rafters, which, in modern buildings, is found unneceffary.

RIGGIL. See RIG and RIDGIL.

RIGGING, a general name given to all the ropes employed to fupport the mafts, and to extend or reduce the fails, or arrange them to the difpofition of the wind.

The former, which are ufed to fuftain the mafts, remain ufually in a fixed pofition, and are called *ftanding* rigging: fuch are the fhrouds, ftays, and backftays. (*Plate* III. *Rigging*, *fig*. 1.) The latter, whofe office it is to manage the fails, by communicating with various blocks, &c. fituated in different parts of the mafts, yards, fhrouds, &c. are comprehended in the general term of *running* rigging: fuch are the braces, fheets, haliards, clue-lines, brails, &c. *Plate* III. *fig*. 2.

The principal objects to be confidered in rigging a fhip appear to be ftrength, convenience, and fimplicity; or the properties of affording fufficient fecurity to the mafts, yards, and fails; of arranging the whole in the moft advantageous manner, to fuccour the mafts, and facilitate the management of the fails; avoiding perplexity, and rejecting whatever is fuperfluous and unneceffary. The perfection of this art, then, confifts in retaining all thefe qualities, and in preferving a judicious medium between them.

Rigging is in part prepared on fhore, in a rigging-houfe, which has the following conveniencies, &c.; *viz.* at the upper end is a windlafs; and at certain diftances down the middle are two rows of large ftrong pofts, for ftretching ropes, and laying on fervice; and on each fide of the houfe are births for the men to ftrop blocks, and prepare fmall rigging on.

There is much fubordinate knowledge neceffary, before a perfon can either prepare rigging in the houfe, or fit it on board the fhip. This confifts of *knotting;* as the overhand knot (*Plate* I. *fig*. 1.); reef-knot, *fig*. 2; bowline-knot, *fig*. 3; wall-knot, *figs*. 4 and 5; double wall-knot crowned, *fig*. 6; buoy-rope-knot, *fig*. 7; ftopper-knot, *fig*. 8; diamond-knot, fingle, *fig*. 9; diamond-knot, double, *fig*. 10; fhroud-knot, opened for knotting, *fig*. 11; as knotted, *fig*. 12; ends tapered and ferved, which completes it, *fig*. 13; tack-knot, *fig*. 14; fprit-fail fheet-knot, *fig*. 15.

Hitches.—Sheepfhank, *fig*. 16; half-hitches, *fig*. 17; clove-hitch, *fig*. 18; rolling-hitch, *fig*. 19; midfhipman's hitch, *fig*. 20; Blackwall-hitch, *fig*. 21; magnus-hitch, *fig*. 22; timber-hitch, *fig*. 23; racking-hitch, *fig*. 24.

Bends.—Sheet-bend, *fig*. 26; Carrick-bend, *fig*. 27; fifherman's bend, *fig*. 30; hawfer-bend, *fig*. 31; temporary bend, *fig*. 32.

Gafket, *fig*. 25; outfide-clinch, *fig*. 28; cat's-paw, *fig*. 29.

Splices.

Splices.—Eye-ſplice, ends opened, *fig.* 33; finiſhed, *fig.* 34; ſhort-ſplice, ends opened and laid together, *fig.* 35; finiſhed, *fig.* 36; long-ſplice, ends opened and laid for ſplicing, *fig.* 37; finiſhed, *fig.* 38; cunt-ſplice, ends opened and laid for ſplicing, *fig.* 39; finiſhed and ſerved over the ſplice, *fig.* 40; cable-ſplice for drawing, ends opened, tapered, and pointed, *fig.* 41; tapered ſhort-ſplice, *fig.* 42. This ſplice is ſerved all over the ſplice.

Hawſer, the ends opened, *fig.* 43; tapered and pointed, *fig.* 44; ditto with a becket, *fig.* 45.

Worming, *fig.* 46; parſling, *fig.* 47; ſerving, *fig.* 48; platting, *fig.* 49.

The ropes, &c. for the ſeveral parts of rigging are, in circumference and in length, according to the eſtabliſhed dimenſions for ſhips of every claſs, particularly in the navy.

There is no one undeviating mode which is purſued in the progreſſive rigging of ſhips. It is an operation which muſt at all times depend upon the time allotted for its performance, and the neceſſity of immediate fitting. The nature of it, however, is ſuch, that all parts may be advancing at the ſame time, the lower maſts and bowſprit being fixed.

Fore, *main*, and *mizen maſts*, have girtline-blocks laſhed round the maſt-head, above the top of the cap, one to hang on each ſide. The girtlines that reeve through them lead down upon deck, for hoiſting the rigging, tops, &c. and the men employed to place the rigging over the maſt-head.

Pendants of tackles are wormed, parcelled, and ſerved with ſpun-yarn, in the way of the ſplice (which is to the ſize of the maſt-head); they have large iron thimbles ſpliced into their lower ends; are then wormed, &c. as above, the whole length in the houſe; and are the firſt thing put over the maſt-head, reſting on the bolſters, they being firſt clothed with worn canvas ſeveral times doubled and tarred. Thoſe over the mizen-maſt are called burton-pendants, as , 2, 3, *Plate* III. *fig.* 1.

Shrouds.—The cablet is warped round two iron fids fixed in the floor, diſtant from each other the length of the firſt warp; that is, from the top of the bolſter to the foremoſt dead-eye; one end of the cablet is made faſt to the lower fid, and the remainder paſſed round the upper fid; and ſo on alternately, one turn cloſe to the back of another. The additional length, gained by the turns lying round each other, is ſufficient for the lengthening of each pair of ſhrouds, as they rake aſt. When the whole gang of ſhrouds is warped out, the bights at the lower end are cut through, in a ſtraight direction, with the fids.

Brigs have four pair of ſhrouds forward, and the foremoſt ſhroud and pendant are in one. The upper bights are deſigned for the eyes, and the outer turns are called *ſwifters*, and are left from four to five feet at each end longer than the ſhrouds, and have an eye ſpliced in them to the ſize of the maſt-head.

The ſhrouds, when cut to their length, are ſtretched for worming by the windlaſs and tackle, and then wormed with double ſpun-yarn one-fourth the length from the centre of the eye on each ſide: but the fore leg of the foremoſt pair is wormed all the whole length. Each length, after being wormed, is hove out, till each pair has acquired, by ſtretching, one and a half the length of the eye; and ſhould remain on that ſtretch twenty-four hours, before the ſervice is laid on.

The eyes of all ſhrouds are parcelled with worn canvas, well tarred, about one fathom and a half on each ſide of the middle for large ſhips, and proportionably for ſmaller; and then ſerved with ſpun-yarn one-fourth of their length; each turn of the ſerving is laid very cloſe, and ſtrained tight round, to prevent the water penetrating. The fore leg of the foremoſt pair of ſhrouds is ſerved the whole length.

Swifters, when ſtretched, have the length of the ſplice ſet off on each ſide of the middle, and likewiſe the length of the eye, or circumference of the maſt-head. The latter is parcelled and ſerved as above. They are then cut aſunder in the middle, and ſpliced to the circumference of the maſt-head; then got on the ſtretch, and ſerved over the ſplice one-fourth of the length.

The bights of ſhrouds are ſeized together to the circumference of the maſt-heads, 1, 2, (*Plate* II. *figs.* 14 and 15.); the ſeizing of the firſt ſhroud is put on below the bolſter or treſtle-trees, with ſeven under and ſix riding turns, and a double croſs over all. The ſeizing of each ſhroud is to be laid its breadth below the next, and clear of each other, to prevent chafing.

Thus far the ſhrouds are prepared in the houſe: they are next hoiſted over the maſt-head. The firſt pair leads down on the ſtarboard ſide forward; the next pair forward on the larboard ſide; then the ſecond pair on the ſtarboard, and the ſecond on the larboard, and ſo on, till all are fixed. By this method, the yards are braced to a greater degree of obliquity, when cloſe hauled; which could not be were the foremoſt ſhrouds laſt fitted on the maſt-head.

Swifters (which are the after ſhrouds) are ſwayed next over the maſt-head above the ſhrouds, and are fixed on the ſtarboard and larboard ſides of the ſhip, to ſupport the maſts, and enable them to bear the ſtrain of a heavy preſs of ſail; as 4, 5, 6, *Plate* III. *fig.* 1.

Stays have an eye ſpliced in one end, 1, (*Plate* II. *fig.* 16.) ſufficiently to receive itſelf through. Each ſtay is got on the ſtretch, and hove well out, as the ſhrouds were; then wormed with ſpun-yarn one-third the length; and then hove out, till the middle ſtrand or heart is made to break in ſeveral places. The mouſe, 2, (*Plate* II. *fig.* 16.) made with ſpun-yarn, &c. in the ſhape of a pear, is then raiſed on the ſtay, at one-third of its length, or by ſome at two ſides of the maſt-head, added to twice the length of the treſtle-trees from the eye to the mouſe. The warp of the mouſe to be marline, and the pointing continued the circumference of the ſtay for the length of the tail. The collar, 3, the eye, 1, and one fathom below the mouſe, 2, to be parcelled with worn canvas, well tarred, and ſerved over with ſpun-yarn. (*Plate* II. *fig.* 16.) The ſtay is hoiſted over the maſt-head, and ſupports the maſt, by extending from its upper end towards the fore part of the ſhip, and counteracts the ſtrain of the ſhrouds which lead aft; and thus is the maſt kept in a firm poſition fore, aft, and ſideways.

Preventer-ſtay is next hoiſted over the maſt-head, the ſame as the former.

Collars.—Fore-ſtay-collars are fitted to the circumference of the bowſprit, and ſpliced together at the ends; wormed, parcelled, and ſerved the whole length; then doubled, and a heart ſeized in the bight. The ſplice is to lie on the back of the heart with *quarter-ſeizings*, a ſcore being cut on each ſide of the heart, large enough to admit from nine to twelve turns of ſeizing; the ſeizing to be ſnaked on the back, to lie cloſely.

Main-ſtay-collar, 4, (*Plate* II. *fig.* 16.) is made by the rope-maker with an eye in one end: in the houſe it is wormed, parcelled, and ſerved round the eye and the whole length.

The fore-ſtay, 7, (*Plate* III. *fig.* 1.) and main-ſtay, have a heart turned into the lower end with a throat-ſeizing, 5, (*Plate*

(*Plate* II. *fig.* 16.) and two round-feizings, 6 and 7, above, and the end of the ftay capped with canvas, whipped and tarred, 8; then fet up with its laniard, 9, (*Plate* II. *fig.* 16.) which is alternately reeved through the heart in the ftay and the heart in the fore-ftay-collar on the bowfprit. The laniard is fet up with a luff-tackle, or luff upon luff, and the four firft turns are ftopt, and fo on, till the laniard is expended: the end is then well ftopt.

The fore-preventer-ftay, 8, (*Plate* III. *fig.* 1.) fets up as the fore-ftay.

The main-ftay, 9, (*Plate* III. *fig.* 1.) fets up as the fore-ftay. Its collar reeves from the ftarboard fide, through a hole in the upper part of the knee next the ftem, (or large triangular eye-bolt drawn through the ftem, in fome merchant fhips,) then paffed through the eye, 10, in the other end, and is brought down to its ftanding-part, and fecurely feized and croffed in two or three places, 11, 12, 13, (*Plate* II. *fig.* 16.) and the end capped; the heart is then feized in the bight above the bowfprit-chock.

The main-preventer-ftay, 10, (*Plate* III. *fig.* 1.) fets up as the fore-ftay, to a heart feized in the bight of its collar, which lafhes round the fore-maft, on the fore-fide through the eyes in the ends, or through bolts in the knight-heads or ftem.

The mizen-ftay, 11, (*Plate* III. *fig.* 1.) fets up through a thimble feized in the collar, which is lafhed round the main-maft, about twelve feet up from the deck. A thimble is turned into the end of the ftay, after it is reeved through the collar, and is fet up with a laniard through an eye-bolt in the deck, abaft the main-maft.

The fhrouds have a dead-eye turned into the lower ends, as 3, (*Plate* II. *fig.* 15.) left-handed, (being cable-laid rope,) with a throat-feizing, 4, clapt on clofe to the dead-eye; and above that a round-feizing croffed, 5, and the end of the fhroud whipt with fpun-yarn, and capped with canvas, 6, well tarred. The laniards, 7, are then reeved through the dead-eyes thus: the end of the laniard is thruft through the after-hole of the dead-eye in the fhroud, and ftopt with a walnut-knot; the other end is paffed through the after-hole of its refpective dead-eye in the chains, 8, then returns upwards, and reeves alternately through the holes in each, and is fet taught with a tackle. It is cuftomary to fet up the fhrouds the firft time with temporary laniards of worn rope and fpun-yarn feizings; and the proper laniards and feizings, when fet up the laft time for fea.

The tops, 12, 13, 14, (*Plate* III. *fig.* 1.) are gotten over their refpective maft-heads by the girtlines.

The futtock-ftaves are wormed, parcelled, and ferved with fpun-yarn the whole length, in the houfe; and then cut to their lengths, as wanted, on board; and are feized along the lower fhrouds horizontally, as much below the upper fide of the treftle-trees as the cap is above. The fhrouds are then *fwiftered* together, thus: a fpar is lafhed to the outfide of the fhrouds, about a fathom below the futtock-ftave; a fingle block is then lafhed round each fhroud and fpar, except the foremoft and aftermoft fhroud, fo that all come in together; the fwiftering-line is then reeved through each block from fide to fide, beginning in the middle, one end leading aft, the other forward; it then croffes, and reeves through two leading blocks, one on each fide the deck, and is bowfed tight, till the fhrouds come in to the length of the catharpin-legs.

Catharpin-legs are four in number. The foremoft is the fhorteft, and they increafe an inch in length as they go aft. The length of the foremoft one is from four feet in fmall, to eight feet in large fhips. They have an eye fpliced in each end, and then wormed, parcelled, and ferved with fpun-yarn the whole length, in the houfe. They are feized through the eye at each end, round the futtock-ftave and fhroud.

Ratlings, 23, 24, 25, (*Plate* III. *fig.* 1.) are faftened horizontally to the fhrouds the firft thirteen inches below the futtock-ftave, and all the others the fame diftance afunder; they are faftened round each fhroud with a clove-hitch, except at the ends, which have an eye, and feized round the fhroud. The foremoft and aftermoft fhrouds are left out for the firft fix ratlings down from the futtock-ftave, and likewife the fix lower ratlings next the dead-eyes. Small fpars, or boats' oars, are feized to the fhrouds, about five feet afunder, for the men to ftand on to rattle down the fhrouds. The fwifters on the fhrouds are next removed half way down between the dead-eyes, and bowfed tight, and fo remain as long as convenient.

The cap is next fwayed up into the top by the girtlines.

Bowfprit.—— *Horfes*, 15, (*Plate* III. *fig.* 1.) The outer ends are fpliced round a thimble in the upper eye-bolt, on each fide the bowfprit-cap. The inner ends have a thimble feized in, and fet up to an eye-bolt in the knight-heads on each fide the ftem with a laniard; the turns are *frapped* together, and the end hitched.

Gammoning, 16, 17 (*Plate* III. *fig.* 1.) The end of the rope is firft whipt, then paffed through the hole in the knee, (but where there is no knee, through a large triangular ring-bolt driven through the ftem,) and over the bowfprit with a round turn, and clinched clofe againft the cleats; the other end is paffed through the fore part of the hole and over the bowfprit, croffing every turn, keeping each turn forward on the bowfprit and aft in the hole, from nine to eleven turns, and every turn is hove tight and *nippered.* The outer end of the bowfprit is fwayed down by a chain-boat, or the fhip's long-boat, loaded with cafks of water, to make it fit clofe on the bed. When all the turns are hove tight, they are frapped together in the middle by as many crofs-turns as are paffed over the bowfprit, which are alfo hove very tight: the end of the gammoning-rope is then whipt, and feized to one of the turns.

Bobftays are wormed, parcelled, and ferved with fpun-yarn three-fourths of their length; and their collars are fitted to the circumference of the bowfprit, with an eye fpliced in each end; they are then wormed, parcelled, and ferved from eye to eye; and have a heart feized in the bight, with a long and fhort leg, with feven under and fix riding turns, well ftrained and croffed with two turns; the end whipt, and fecured with a walnut-knot, in the houfe. The bobftay-collar is lafhed upon the upper fide of the bowfprit at two-thirds out, or within the faddle for the fpritfail-flings, with from eight to ten turns through the eyes, and hove tight by a *heaver.* Ships in the navy generally have two pairs of bobftays, 18, 19, (*Plate* III. *fig.* 1.), merchant-fhips commonly but one pair; one end is paffed through a hole in the front of the knee, or large triangular eye-bolt in the ftem; the ends are then fpliced together. A heart, or dead-eye, is feized in the bight, the fplice to come on the heart; it is then fet up with a laniard, paffing through the heart in the ftay, and its collar by a luff-tackle.

Shrouds, 20, (*Plate* III. *fig.* 1.) are cable-laid rope; they have an iron hook and thimble fpliced in the inner ends, and are ferved over the fplice. They hook to an eye-bolt on each fide the bow; the fore-ends have a heart, or dead-eye, feized in, and they are fet up the fame as the bobftays.

The ufe of the bobftays and fhrouds is to draw down, and keep fteady, the bowfprit; to counteract the force of the ftays of the fore-maft, which draw it upwards.

Topmafts.—The girtlines may now be taken down from the

the lower maſt-heads, and one of the top-blocks ſecurely laſhed round the maſt-head below the cap. The end of a hawſer is then led up from aft, outſide the treſtle-trees, and reeves through the top-block at the maſt-head, then leads down inſide the fore part of the treſtle-trees, and reeves through the ſheave-hole in the heel of the topmaſt, and is racked to the topmaſt in two or three places between the heel and the hounds; it is there well ſtopt with three-quarter laſhing, and enough of the end left to make faſt round the maſt-head. The other end of the hawſer is led to the capſtan. When the topmaſt is hove high enough to enter the treſtle-trees, the end of the hawſer is made faſt round the maſt-head: the lower cap, 32, 33, 34, (*Plate* III. *fig.* 1.) is then lifted over the head of the topmaſt, and ſecurely ſtopt with laſhing a little below the hounds. The topmaſt is now hove high enough for the cap to enter over the lower maſt-head, and then lowered, that the cap may be beaten down firmly on the maſt-head with malls; then the laſhings may be caſt off, and as the topmaſt is raiſed the rackings are cut looſe.

Top-rope-pendants have a large thimble ſpliced in the lower end, and are marled over the ſplice in the houſe, and pointed when on board. The top-rope-pendant is then reeved through the top-block, which is hooked to an eye-bolt on one ſide the lower cap, next through the ſheave-hole in the heel of the topmaſt, then led upwards, and made faſt to an eye-bolt in the cap oppoſite to the top-block. Through the thimble, at the lower end of the pendant, is hooked the block of the top-tackle; its lower block is hooked to an eye-bolt in the deck, and the fall brought to the capſtan. The girtline-blocks are now laſhed to the topmaſt-head, and the topmaſt-croſs-trees and cap are ſwayed up into the top, and the croſs-trees, 35, 36, 37, (*Plate* III. *fig.* 1.) fixed on the maſt-head.

Burton-pendants for the mizen-maſt, 3, and topmaſts, fore and main, 21, 22, (*Plate* III. *fig.* 1.), have a ſplice in the middle to the circumference of their reſpective maſt-heads; thimbles ſpliced in their lower ends; and ſerved with ſpun-yarn over the ſplices in the houſe. The burton-pendants are hoiſted by the girtlines, and placed over the topmaſt-head, that the thimbles may hang on each ſide, to which are hooked the burton-tackles.

Shrouds are warped out on the floor, as the lower ſhrouds are, and fitted to the circumference of the topmaſt-head. In the foremoſt ſhroud, on each ſide, is ſeized a ſiſter-block, 2, (*Plate* II. *fig.* 14.), below the futtock-ſtave, in the houſe. They are ſwayed up and placed over the topmaſt-head, 41, 42, 43, (*Plate* III. *fig.* 1.); the firſt pair to lead down on the ſtarboard ſide forward, the next pair on the larboard ſide forward, and ſo on with the other two pair. The dead-eyes are turned in to their ends the ſame as the lower eyes are, and are ſet up with laniards to the dead-eyes in the futtock-plates by the burton-tackles.

Futtock-ſhrouds, 26, 27, 28, (*Plate* III. *fig.* 1.) The whole-lengths are divided into four, and cut in the bights. Each length has a hook and thimble ſpliced in each end, and the ends of the ſplices ſtopt with ſpun-yarn; then doubled, and a ſpun-yarn tied in the middle for the cutting-mark. The hooks are then hooked in each other, and got upon the ſtretch. They muſt be well hove out, in order to try the hooks and ſplices, as the topmaſt, &c. depends very much thereon. If a hook ſhould break, or a ſplice draw, the former muſt be ſhifted, and the latter hauled tighter through. After they are ſufficiently ſtretched, the ends of the ſplices are tapered, marled down, and ſerved with ſpun-yarn within two feet of the cutting-mark; then cut aſunder, and the ends whipt. On board, their upper ends hook to a hole in the lower end of the futtock-plates, and the lower ends of the futtock-ſhrouds are made faſt to the lower ſhrouds, with a round turn round the futtock-ſtave and ſhrouds, and ſeized up on the ſtanding-part of the ſhroud with two ſeizings croſſed.

Stays are ſwayed up and placed over the topmaſt-head next the ſhrouds, in their order thus: the breaſt-backſtay firſt, and the ſtanding-backſtay next; then the topmaſt-ſtay; and, laſtly, the topmaſt-preventer-ſtay.

Topmaſt-caps, 38, 39, 40, (*Plate* III. *fig.* 1.) may now be lifted on the topmaſt-head, and beat down firm; the girt-lines unlaſhed and taken down, and the topmaſt hove up and fidded. Then ſet up the ſhrouds, 41, 42, 43, (*Plate* I. *fig.* 1.), and rattle them down, as before directed. Set up the breaſt-backſtay, &c. thus: the ***breaſt-backſtay***, 44, 45, (*Plate* III. *fig.* 1.) has a ſingle block turned into the lower end, with a throat and round-ſeizing, through which reeve the runner, one end of which is made faſt to the chain-plates, abreaſt the maſt, with a half-hitch, and the end ſeized down. In the other end is ſpliced a double block, connected by its fall to a double block that is ſtrapped with an eye, through which a ***ſpan*** is reeved, that has an eye ſpliced in each end, by which it is laſhed to the chain-plates.

Standing-backſtays, 46, 47, 48, (*Plate* III. *fig.* 1.) are ſet up, the ſame as a ſhroud, to a ſmall dead-eye in the after-end of the channel.

Shifting-backſtays, 49, 50, 51, (*Plate* III. *fig.* 1.) are clinched round the topmaſt-head and a thimble ſpliced in the lower end, to which is hooked a tackle, the lower block of which is hooked to an eye-bolt over the ſide, and frequently ſhifted, ſo as to render the topmaſt under a preſs of ſail of the greateſt aſſiſtance.

Fore-topmaſt-ſtay, 52, and *fore-topmaſt-preventer-ſtay*, 53, (*Plate* III. *fig.* 1.) are ſet up by paſſing the end through a ſheave under the ***bees*** of the bowſprit; then a long tackle-block is turned into the ends, which is connected by its fall to a ſingle block hooked to an eye-bolt in the bow on each ſide, and ſet up with a luff-tackle, cat's-pawed to its fall. When the ſtay is ſet up, the parts of the tackle are ſtopt together with a rope-yarn, and the fall of the long-tackle is paſſed through the eye-bolt and arſe of the block alternately till it is expended; the end is then made faſt round all the parts with two half-hitches.

Main-topmaſt-ſtay, 54, (*Plate* III. *fig.* 1.) reeves through a ſingle block, ſtrapped with a long and ſhort leg; the ſhort leg has an eye ſpliced in it, the long leg goes round the fore-maſt-head above the rigging, and through the eye of the ſhort leg, and is turned back and ſeized. The ſtay, having a thimble turned in the lower end, leads down between the cat-harpins and the maſt, and ſets up with a laniard to an eye-bolt in the deck, cloſe abaft the maſt.

The ***preventer-ſtay***, 55, (*Plate* III. *fig.* 1.) reeves through a thimble ſeized in the bight of a collar, that is laſhed cloſe up to the ***bibs*** of the fore-maſt, and then ſet up to an eye-bolt, as the topmaſt-ſtay.

Mizen-topmaſt-ſtay, 56, (*Plate* III. *fig.* 1.) reeves through a thimble ſeized in the bight of the collar, that is laſhed cloſe up to the ***bibs*** of the main-maſt; a thimble is then ſpliced into the end of the ſtay, which is ſet up by its laniard to a thimble in another collar, that is laſhed round the maſt, a little below the cat-harpins.

When the *ſtays* are ſet up very tight, the ſhrouds and backſtays muſt be caſt off, and the maſt-head gotten ſo far forward as nearly to touch the fore part of the partners by the runners and tackles, 29, 30, (*Plate* III. *fig.* 1.) or burtons of the mizen-maſt, 31, (*Plate* III. *fig.* 1.) The pendants are frapped together abaft their reſpective maſts, and the runners made faſt as far as convenient before the maſt, and the falls led to the capſtan or windlaſs.

Lower

Lower Yards.—The lower yards muft firft be gotten on board thus: the hawfer that hove up the topmaft is made faft round the yard with a round turn and two half-hitches, fecurely ftopt with fpun-yarn along the yard in feveral places, and well ftopt at the upper arm. As the yard is hove on board, the ftops are cut, and the runner-tackle of the oppofite fide is brought on to the quarter of the yard, to affift it in lowering as the yard advances on board beyond the flings. They are laid athwartfhips before their refpective mafts, but the fore-yard muft be kept above the main-ftay by the runners, which are made faft round each quarter of the yard. They are then rigged as follows.

Horfes, 1, 2, 3, (*Plate* III. *fig.* 2.) have an eye fpliced in one end to the circumference of the yard-arm, and ferved with fpun-yarn over the fplice. The eye goes over the yard-arm, 1, and ftops againft the cleats, and the other end reeves through the thimble in the lower end of the ftirrups, 2, which are from three to four in number; the inner end of the horfes then have a thimble turned in, with a throat and round feizing, through which they are lafhed to the yard, juft beyond the fling-cleats on the oppofite fide. The ftirrups, 3, (*Plate* II. *fig.* 17.) have their upper ends opened and plaited, and are faftened to the yard at equal diftances with three round turns, and nailed, fo as that the horfes may hang fufpended about three feet below the yard.

Yard-tackle-pendants, 4, 5, 6, 7, (*Plate* III. *fig.* 2.) have an eye fpliced in one end the fize of the yard-arm, 4, and a double block in the other end, 5, and the fplices ferved over with fpun-yarn in the houfe. The eye is put over the yard-arm next the horfes, and the double block is connected by its fall to a fingle block ftrapped with a hook and thimble, 6, *Plate* II. *fig.* 17.

Brace-pendants, 8, 9, 10, 11, 12, 13, (*Plate* III. *fig.* 2.) have an eye fpliced in one end, as in the former, and a fingle block in the lower end, and the fplices ferved over with fpun-yarn in the houfe. They, like the former, are next put over the yard-arm, 7, and the brace reeved through the fingle block, 8, (*Plate* II. *fig.* 17.) Sometimes in the navy, but moftly in merchant-fhips, the block is lafhed clofe up to the yard, without a pendant. *Fore-braces* have their ftanding-part made faft round the collar of the main-ftay, on each fide, with a hitch, and the end feized. The leading-part reeves through a fingle block, lafhed on each fide the main-ftay-collar, clofe up to the rigging, and leads down and paffes through a fheave in the brace-bitts, at the fore part of the quarter-deck. The *main-braces* have their ftanding part made faft with a clinch round an eye-bolt in the upper part of the quarter-piece: the leading-part reeves through a fixed block clofe aft upon the plank-fheer, or a block lafhed to an iron ftay projecting on the fide, and leads in and belays round a cleat on the infide. The ftanding and leading-parts of the main-brace are led aft through a thimble fpliced in the end of a *fpan* with two legs, which is made faft with a half-hitch round the mizen-fhrouds on each fide.

Preventer-braces to the fore-yard, in war, reeve through a block lafhed round the yard-arm, 9, (*Plate* II. *fig.* 17.) and through a block in a fpan, hitched round the bowfprit-cap; they lead in upon the forecaftle, and the ftanding-part makes faft round the cap. Thofe to the main-yard reeve through the block on the yard-arm, then through a block lafhed to the fore-fhrouds, clofe below the cat-harpins, lead down upon the forecaftle, and the ftanding-part makes faft to the fhrouds above the block with a hitch, and the end is feized.

Topfail-fheet-blocks are next put over the yard-arms, 8, 9, 10, 11, (*Plate* III. *fig.* 2.), ftrapt with an eye to the fize of the yard-arm, 10, *Plate* II. *fig.* 17.

Lift-blocks are then fpliced into the ftraps of the topfail-fheet-blocks, 11, (*Plate* II. *fig.* 17.); the lifts, 12, 13, 14, 15, 16, 17, (*Plate* III. *fig.* 2.) reeve through a block in a fpan, hitched round the maft-head, between that and the topmaft, then lead down abreaft the fhrouds, and reeve through a block faftened to the fide, and there belay.

Quarter-blocks, 18, 19, (*Plate* III. *fig.* 2.) are ftrapt with a long and fhort leg, with a lafhing-eye fpliced in each end, through which they lafh round the middle of the yard, within the cleats, the block hanging downwards, 11, *Plate* II. *fig.* 17.

The quarter-block is a double block, with a thick and thin fheave running on the fame pin, through which reeve the topfail-fheets, and the thin fheave is intended for the clue-lines; but a fingle block, in lieu of them, is recommended, as they would lead fairer and work eafier. Large merchant-fhips have a fingle block lafhed on each fide of the middle of the yard, and the fheets reeve on their refpective fides, and lead down by the fides of the maft. Smaller fhips have a double block lafhed in the middle of the yard, as the quarter-block, through which the fheets reeve, and lead down on oppofite fides.

Clue-garnet-blocks, 12, (*Plate* II. *fig.* 17.) lafh through the eyes upon the yard, the blocks to hang downwards, four feet without the fling-cleats, on each fide.

Leech-line-blocks, 13, (*Plate* II. *fig.* 17.) are lafhed through the eye and round the yard, ten feet within the cleats at each yard-arm. The blocks to hang on the fore-fide of the yard.

Bunt-line-blocks, 14, (*Plate* II. *fig.* 17.) are lafhed, like the former, midway between them and the flings.

Slab-line-blocks, 15, (*Plate* II. *fig.* 17.) are ftrapt with a fhort lafhing-eye, and are feized to the fpan of the quarter-blocks underneath the yard.

Tricing-blocks, 16, (*Plate* II. *fig.* 17.) for the yard tackles are ftrapt as the above, and are feized round the yard about one-third the length within the arm-cleats. The blocks to hang under the yard.

The *inner tricing-line*, 20, (*Plate* III. *fig.* 2.) reeves through a block lafhed to the futtock-ftave, has a long-eye fpliced in the outer end, the bight is put over the hook of the fingle block with a couple of turns, 17, (*Plate* II. *fig.* 17.), and the leading-part belays to the fhrouds. At fea it is hooked to a becket, or ftrap, round the futtock-ftaff. The *outer tricing-line*, 21, (*Plate* III. *fig.* 2.) is fpliced round the ftrap of the yard-tackle-block, 18, (*Plate* II. *fig.* 17.), and reeved through a block on the yard, it then reeves through a block lafhed in the fhrouds near the futtock-ftaff, and leads down upon deck.

Jeers, in large fhips, are two large tackles, 22, 23, (*Plate* III. *fig.* 2.) The blocks at the maft head are hove up clofe on each fide by the top-burton tackles, and fo lafhed, that every turn of the lafhing is alternately paffed through the ftrap of the block (*Plate* II. *fig.* 11.), and over a broad elm-cleat, nailed on the oppofite fide of the maft-head, and the ends of the lafhing are well ftopt. The other two blocks are ftrapt with a double ftrap to the fize of the yard, with a long and fhort leg (*Plate* II. *fig.* 10.) (See *Strapping of Blocks*, below.) They lafh on each fide the middle, or flings, within the cleats, 19, 20, (*Plate* II. *fig.* 17.) The long leg of the ftrap is paffed down the aftfide of the yard, and meets the bight of the fhort leg on the forefide, and lafhes, every turn paffing alternately through each bight, rofe-fafhion. The falls reeve through the blocks at the maft-head and on the yard, and lead down upon deck. Jeers, in merchant-fhips, and fmall fhips in the navy, have two fingle blocks lafhed on each fide the maft-head, as above, and another, the fame fize, in the middle of the yard. The *tye* then reeves through one of the blocks at the maft head, then through the block on the yard, and then through the block

on

on the oppoſite ſide of the maſt-head. In the lower ends of the tye is ſpliced a double block, with its fall, which reeves through another double block, that hooks to an eye-bolt in the deck. The fall of the jeers leads through the bitts to the capſtan, by which the yards are hoiſted up in their place.

Truſs-pendants are doubled, and cut in the bight; they have a thimble ſpliced into one end, and are ſerved with ſpun-yarn one-third the length, in the houſe. The ends that have the thimbles are paſſed round the yards within the ſling-cleats, and are well ſeized. One end paſſes over the yard, the other under, and both ends round the maſt. The ſtarboard end reeves through the larboard thimble, and the larboard end through the ſtarboard thimble. The lower end has a double block turned in, with a throat and round-ſeizing, and its fall reeves through a double block that hooks to an eye-bolt in the deck, on each ſide the maſt, by which the truſs-pendant is ſtraightened or ſlackened, conſequently the yard is cloſe confined, or removes from the maſt.

The *nave-line* reeves through a ſingle block laſhed under the aftſide of the top, and through a block or thimble ſeized to the truſs-pendants; one end leads upwards, and makes faſt round the treſtle-trees. The leading-part goes down upon deck.

Slings and Straps.—The ſtrap has an eye ſpliced in each end, with a long and ſhort leg, to the circumference of the yard, and ſerved with ſpun-yarn from eye to eye, with a thimble ſeized in the bight. The ſlings have an eye ſpliced in one end, then wormed, parcelled, and ſerved almoſt the whole length, in the houſe.

The long leg of the ſtrap paſſes down the aftſide of the yard, exactly in the middle, comes up the foreſide, meets the ſhort leg, and laſhes through the eyes, the thimble to be upwards. The ſlings have a large thimble ſeized to the bight with a long and ſhort leg. The long leg paſſes round the after-part of the maſt, and reeves through the eye in the ſhort leg; it is then returned back, and ſecurely ſeized to its own part in ſeveral places. By theſe the yards are ſlung at the maſt-head by a laniard, that ſplices in the thimble in the ſlings at the fore-part of the maſt, and then reeves through the thimble in the ſtrap upon the yard, and alternately till the laniard is expended; the end then fraps round the turns, and makes faſt with two half-hitches. In time of action, the yards are ſlung with chains.

Strapping of Blocks in the Houſe.

A TABLE of the Dimenſions of Straps for Laſhing and Seizing Blocks.

Size of the Blocks.	Size of the Straps.	Length of the Straps.	
Inches.	Inches.	Feet.	Inches.
17	5	7	6
16	4½	6	9
15	4	6	0
14	3½	5	6
13	3½	5	0
12	3½	4	6
11	3	4	3
10	3	3	9
9	2½	3	6
8	2½	3	0
7	2½	2	9
6	2	2	6
5	1½	1	9
4	¾	1	6

The whole length of all the different ſizes of block-ſtrapping is gotten upon the ſtretch, and hove out tight for worming and ſerving; after that is performed, it is cut into lengths agreeable to the above table, according to the ſize of the blocks. The ſcores of all blocks, if required, are to be opened, or eaſed, ſo as to receive the ſtrap, and then to be well tarred, and the pin and ſheave examined, before the ſtrap is put on (*Plate* II. *fig.* 1.) The block is then ſet well into the ſtraps with wedges, thus: the ſtrapping is frapped together with rope-yarn under the block, with a chock between, and the wedges are ſet between the breaſt of the block and the chock. The ſtrap is next nippered, with a heaver, round the block; the wedge, chock, and frappings are then removed, and the block hung up, that the ſtrap may be well ſeized together, cloſe under the block, with nine under and eight riding turns; every turn ſtrained tight round with a heaver, and croſſed each way with two turns.

Jeer-blocks (*Plate* II. *figs.* 10, 11.) are double ſcored, conſequently ſtrapped with a double ſtrap, thus: it is ſpliced together at the ends, and when doubled, ſhould be the ſize of the block and the circumference of the yard. It is then doubled, and the block ſeized in the bight, with a long and ſhort leg, the ſplice lying in the arſe of the block. Jeer-blocks for the maſt-heads are ſtrapped with long-eyes, to receive many turns of the laſhing.

Blocks ſtrapped with a thimble, or hook and thimble, (*Plate* II. *fig.* 3.) have the ends of the ſtraps ſpliced together. The block is fixed in one bight, for the ſplice to lay, as above, and the thimble in the other bight; the ſeizing is clapt on, between the block and the thimble, with eight under and ſix riding turns, according to the ſize of the block; each turn ſtrained by a heaver, turns double-croſſed, and the end ſtopt with a wall-knot crowned.

Blocks ſtrapped with eyes (*Plate* II. *figs.* 4, 5, 6.), or thimbles ſpliced in the ends, are ſeized tight into the bight, and the legs left long enough to laſh through the eyes, round their reſpective maſt, yard, &c. as the topſail, clue-lines, clue-garnets, &c.

Blocks ſtrapped with double tails are ſeized in the bight as the former; but thoſe with a ſingle tail are ſpliced in, and ſerved with ſpun-yarn over the ſplice.

The ſtrapping of jeer-blocks is wormed, parcelled, and ſerved. Strapping of four inches diameter, and above, is wormed and ſerved; and all under four inches is only ſerved with ſpun-yarn; except the ſpritſail-brace, buntline, and leech-line blocks, that are laſhed under the tops, which are only ſerved with ſpun-yarn over the ſplice, and the tail left half a fathom in length.

Rigging the Topſail Yards.

The topſail-yards are firſt hove on board by the top-rope, which is faſtened to the ſlings of the yard, and ſtopt from thence with ſpun-yarn to the yard-arm, and placed athwart their reſpective maſts.

Horſes, 1, rig the ſame as the lower yards, with the addition of *Flemiſh horſes*, 2, (*Plate* II. *fig.* 18.) which have an eye ſpliced in each end; one eye is put over the eye-bolt in the yard-arm, and the other is ſeized round the yard within the arm-cleats, 24, 25, 26, *Plate* III. *fig.* 2.

Brace-pendants, 3, (*Plate* II. *fig.* 18.) are next put over the yards, as on the lower ones. The fore-topſail-braces reeve through the block in the pendant, and then through a block laſhed on each ſide to the main-ſtay-collar, a little below the fore-braces; the ſtanding-part makes faſt to the ſtay with a hitch, and is ſeized below the block. The leading-part leads from the block on the collar, through a block laſhed on the ſtay,

ſtay, over the fore hatchway, and through a block ſtrapped with a thimble into an eye-bolt in the aft-part of the fore-caſtle, and belays to a pin in the ſkid-beams, 27, 28, *Pl.* III. *fig.* 2.

The main-topſail-braces reeve through the block in the pendant, and the ſtanding-part makes faſt to the mizen-ſtay collar. The leading-part reeves through a block in the ſpan round the mizen-maſt-head below the hounds, and through a ſheave-hole in the mizen-topſail-ſheet-bitts, abaft the mizen-maſt, and belays there; 29, 30, *Plate* III. *fig.* 2.

The mizen-topſail-braces reeve through the block in the pendant. The ſtanding-part makes faſt round the peek-end, and the leading-part reeves through ſingle blocks at the peek, and comes down and belays to the fore-ſide of the taffarel to a cleat; 31, 32, *Plate* III. *fig.* 2.

Reef-tackle-pendants, 4, (*Plate* II. *fig.* 18.) reeve through the upper ſheave in the *ſiſter-block* in the topmaſt-ſhrouds, thence through a ſheave-hole in the yard-arm, and are ſtopt with an over-hand knot, till the ſail is bent. A double block is turned in to the lower ends of the pendants, and its fall reeves through another double block, that is ſeized to the after-part of the lower treſtle-trees, and the falls lead down upon deck; 33, 34, 35, 36, *Plate* III. *fig.* 2.

Lift-blocks, 5, (*Plate* II. *fig.* 18.) are ſtrapt with an eye to the ſize of the yard-arm. The lift reeves through the lower ſheave in the ſiſter-block in the topmaſt-ſhrouds, and through the block on the yard-arm. The ſtanding-part hooks to a becket round the top-maſt-cap, and the leading-part leads down the ſide of the maſt, and belays to the dead-eyes in the lower ſhrouds; 37, 38, 39, 40, 41, 42, *Plate* III. *fig.* 2.

Tye-blocks, thoſe at the topmaſt-heads, laſh cloſe up to the rigging, under the collar of the ſtay; and the blocks on the yard, 6, (*Plate* II. *fig.* 18.) laſh under the fore-part of the yard, as the lower ones. The ſtanding-part of the double-tyes in large ſhips clinch round the maſt-head, then reeve through the double block upon the yard, return upwards, and reeve through the block on each ſide the maſt-head; 43, 44, 45, (*Plate* III. *fig.* 2.) The fly-blocks are then ſpliced in their lower ends, and connected by their haliards to a ſingle block, that is ſtrapt with a long ſtrap, with a hook and thimble, that hooks to a ſwivel-eye-bolt in the channel on each ſide: the leading-part comes in-board through a block laſhed on each ſide; the foremoſt ones abaft the forecaſtle, and the after-ones on the quarter-deck. A ſingle tye rigs like the lower yards in ſmall ſhips.

Buntline-blocks are ſpliced round the ſtraps of the top-ſail-tye-block upon the yard, 7, *Plate* II. *fig.* 18.

Clue-line-blocks are ſtrapt with two laſhing-eyes, and laſh upon the yard, three feet without the ſlings, the blocks hanging under the yard, through which the clue-lines reeve and lead down upon the deck, 8, *Plate* II. *fig.* 18.

Top-gallant-ſheet-blocks, 9, (*Plate* II. *fig.* 18.) are ſtrapt with two laſhing-eyes, and laſh upon the yard, cloſe within the clue-line blocks on each ſide.

Parral. (*Plate* II. *fig.* 20.) The parral-ropes in the houſe have an eye ſpliced in each end, are wormed and ſerved with ſpun-yarn from eye to eye, then doubled, and cut aſunder in the bight. The end of one rope is thruſt through the upper hole in the ribs, and a truck, alternately. The end of the other rope is paſſed through the lower hole in the ribs and a truck the reverſe way. The parral is fitted to the aft-ſide of the topmaſt, and the eye in one end paſſed under the yard, and the other over, till both eyes meet and are ſeized together on the fore-ſide with ſpun-yarn. The other ends of the parral-rope are paſſed round the yard and aftſide of the parral alternately, till the latter is well ſecured to the former; and the whole of the turns are marled together with quarter-ſeizings, to confine them cloſe in the cavity on the aftſide of the ribs. Thus the yard is confined to the maſt, but eaſily hoiſted or lowered when the maſt is kept clean and greaſed.

Jib-boom to be rigged.—The jib-boom is hoiſted on board and laid on the bowſprit, and its fore end pointed through its hole in the bowſprit-cap. The heel-rope or top-rope may be reeved through the ſheave-hole at the heel, and one end made faſt to the eye-bolt on one ſide of the bowſprit-cap, the other reeved through a ſingle block made faſt to an eye-bolt on the oppoſite ſide, and lead in upon the forecaſtle, 46, *Plate* III. *fig.* 2.

The *traveller* is firſt put over the outer end of the jib-boom, and the hook kept inwards; 47, *Plate* III. *fig.* 2.

Horſes are doubled, and ſerved with ſpun-yarn one fathom in length in the bight, and knotted with an over-hand knot, at the diſtance of every yard, in the houſe. On board, the bight is taken over the outer end of the jib-boom, with a jambing-knot, cloſe againſt the ſtop, which prevents them coming in. The inner ends are brought aft and made faſt, with a round turn round the jib-boom, within the cap. The ends are ſtopt back with two or three ſeizings of ſpun-yarn, to prevent their being caſt off by miſtake; 57, *Plate* III. *fig.* 1.

Guy-pendants are put over the jib-boom, the ſame as the horſes, and the inner ends reeve through a thimble, on the quarters of the ſpritſail-yard, and turn in to the ſtrap of a double block, with a throat and round-ſeizing, and its fall reeves to a ſingle block, that hooks to an eye-bolt near the cat-head, and leads in upon the forecaſtle; 49, 50, *Plate* III. *fig.* 2.

A *ſtrap* is put over the end of the jib-boom, with three thimbles ſeized in it; the middle thimble is the largeſt, and reeves the fore-top-gallant-ſtay, and the ſmaller thimbles on each ſide the fore-top-gallant-bowlines.

The *ſpritſail-yard* is hove on board, and laid fore and aft the forecaſtle for rigging with its *horſes*, 51, 52, (*Plate* III. *fig.* 2.) The eye in the outer end is put over the yard-arm on each ſide, and ſtops againſt the cleats. The eye in the other end is well ſeized to the yard, at three feet beyond the ſlings, with *ſtirrups* and *Flemiſh horſes*, the ſame as the topſail-yards, 53, *Plate* III. *fig.* 2.

Braces and Pendants.—The eye in one end of each pendant goes over the yard-arm cloſe againſt the horſes, and the brace reeves through a ſingle block ſpliced in the other end; the ſtanding-part makes faſt to the ſtay-collar, and the leading-part reeves through a double block, made faſt under the fore-top, and then leads through another, made faſt to the aft-part of the top, and down to the aft-part of the forecaſtle; 54, 55, *Plate* III. *fig.* 2.

Lifts.—The blocks are ſtrapped with an eye to the ſize of the yard-arm, and driven thereon cloſe to the braces. The lift reeves through a ſingle block in the end of a *ſpan*, which is paſſed with a hitch round the cap under the jib-boom, and through the block on the yard-arm, and the ſtanding-part returns upwards, and is made faſt to an eye-bolt in the ſide of the cap; the leading-part comes in upon the forecaſtle. They are occaſionally uſed for ſpritſail-topſail-ſheets.

The *ſtanding-lift* has an eye ſpliced in one end, and laſhes to the yard one-fourth from the ſlings: the other end has a thimble ſpliced in, and is ſet up with a laniard to a thimble ſpliced in a ſtrap that is hitched round the bowſprit within the *bees*; 56, 57, *Plate* III. *fig.* 2.

Clue-line-blocks are ſtrapped with two eyes, and are laſhed

lashed through those eyes round the yard three feet without the slings, the lashing to be upon the yard.

The *strap* has a thimble seized in the bight, and is spliced or seized round the yard in the middle, between the cleats. Also on each quarter of the yard is seized a strap, with a thimble, through which are led the jib-guys. The yard may now be hove out towards its place, and the long-tackle block of the haliards hooked into an eye-bolt in the after-part of the bottom of the bowsprit-cap; the hook to be moused with spun-yarn, to prevent its slipping loose. The single block is hooked to the thimble in the strap at the slings, and the fall then leading in upon the forecastle, the yard is hove to its place.

The *slings* have an eye spliced in each end, one of which goes round the yard close within the cleats near the middle, and seizes with a quarter-seizing close to the yard; the other end goes over the bowsprit before the saddle, and under the yard, then over the bowsprit again, till the eyes in the ends, meeting close together, are well lashed.

Preventer-slings are used when the haliards are taken in. The outer end has a hook and thimble spliced in and served down over the splice, that hooks to the eye-bolt in the bottom of the cap. The inner end reeves through the thimble in the strap at the slings, and is hitched with two half-hitches, or spliced.

The *spritsail-topsail-yard* is hove on board, &c. as the former, and the

Horses, having an eye in their outer ends, are put over the yard-arm on each side, and stop against the cleats; the inner end has an eye, which is seized to the yard, three feet without the slings, 58, *Plate* III. *fig.* 2.

The *braces* have an eye spliced in one end, that goes over the yard-arm on each side; the inner ends lead through a block made fast to the under side of the fore-top, from thence through another at the aftside under the top, and lead down to the aft-part of the forecastle, and there belay; 59, *Plate* III. *fig.* 2.

The *lifts* have an eye spliced in their outer ends, and are driven over the yard-arm close to the braces; the inner end reeves through a thimble, seized on each side a strap hitched over the end of the jib-boom, and leads in upon the forecastle through a saddle on the bowsprit, and belays to the rack over the bowsprit, 60, *Plate* III. *fig.* 2.

The *clue-line-blocks* are strapped with two eyes, and are lashed through those eyes round the yard, about two feet without the slings.

Haliard.—The standing-part is made fast with a bend through the becket of its block, lashed under the outer end of the jib-boom; then reeves through a single block, lashed round the middle of the yard between the cleats; then forward, and reeves through the block at the outer end of the jib-boom, and leads in upon the forecastle, and belays to a rack over the bowsprit, 61, *Plate* III. *fig.* 2.

Top-gallant Masts.—The *top-rope* reeves for the top-gallant-mast as it does for the topmast, observing to stop it to the top-gallant-mast-head with spun-yarn, to keep it steady till it has entered the topmast-cap; the stop is then cut, and the end of the top-rope made fast to the eye-bolt in the topmast-cap.

A grommet of rope, spliced to the size of the mast, is first put over the head, and beat down close to the stop of the hounds.

Shrouds, *backstays*, and *stays*, are fitted in the house, and hoisted over the top-gallant-mast-head, the same as the topmasts, and the top-gallant-mast is then swayed up and fidded.

The *shrouds* are then thrust through a hole in the end of the topmast cross-trees, and between the topmast shrouds, over the futtock-staff. A thimble is seized in the ends that set up with the laniard through a thimble seized in the bight of a strap, made fast round the futtock-plates, close under the dead-eyes, with a turn through the bight, 58, 59, 60, *Plate* III. *fig.* 1.

Backstays set up, the same as the topmast-backstays, to a small dead-eye in the aft-part of the channel, or in a stool abaft the channel, 61, 62, 63, *Plate* III. *fig.* 1.

Fore-top-gallant-stay, 64, (*Plate* III. *fig.* 1.) reeves through a single block in large ships, or a thimble in the strap at the outer end of the jib-boom of frigates and smaller vessels. The former sets up by its tackle to an eye-bolt in the head; the latter with a jigger-tackle occasionally, and is secured by a laniard to the gammoning or eye-bolt in the head.

Main-top-gallant-stay, 65, (*Plate* III. *fig.* 1.) is cable-laid in large ships, and fitted with a collar and moused, as the lower stays. Smaller ships are hawser-laid, have an eye spliced in the upper end to the circumference of the mast-head, and served with spun-yarn over the splice, in the house. It reeves through a single block at the fore-top-mast-head, has a thimble turned into the end of the stay, and sets up to a thimble in a span, made fast to the trestle-trees of the foremast by its laniard.

Staysail-stay, 1, (*Plate* IV. *fig.* 1.) is spliced into the top-gallant-stay, one fathom below the top of the mast, it then reeves through a block or thimble lashed to the fore-top-mast-head, takes a turn round the trestle-trees, and belays there.

Mizen-top-gallant-stay, 66, (*Plate* III. *fig.* 1.) sets up to the main-topmast-head, as the main-top-gallant-stay sets up to the fore-topmast-head.

Flag-staff-stays go round their respective top-gallant or royal mast-heads with a running-eye, and are kept close up under the truck, by a small cleat nailed on each side. The fore one reeves through a thimble at the jib-boom end, and belays round the fore-stay-collar. The main one reeves through a thimble above the fore-top-gallant rigging, and belays in the top. The mizen one the same above the main-top-gallant rigging.

Royal masts are rigged as top-gallant-masts, and often abaft the mast.

The *top-gallant-yards* are hove on board, and rig with horses, braces, and lifts, over the yard-arm, the same as the topsail-yards.

Braces, 1, (*Plate* II. *fig.* 19.) The fore-top-gallant-braces, 56, (*Plate* III. *fig.* 2.) reeve through the block in the pendant of large ships, or the block in the yard-arm of small. The standing-part makes fast with a hitch, and the end seized back round the collar of the main-topmast-stay on each side; and the leading-part reeves through a block lashed round the collar a little below the standing-part; then leads through a block at the aft-part of the fore-top, and belays to a pin at the aftside of the forecastle.

The *main-top-gallant-braces*, 57, (*Plate* III. *fig.* 2.) reeve as the former. The standing-part makes fast with a hitch, and the end seized back round the collar of the mizen-topmast-stay, and the leading-part through a block seized just below the standing-part, and leads down into the mizen-shrouds.

The *mizen-top-gallant-braces*, 58, (*Plate* III. *fig.* 2.) are single, and go with a splice over the yard-arm. They lead through a thimble at the mizen-peek, come down, and belay to a cleat on the fore-side of the taffrail.

The *lifts*, 59, 60, 61, (*Plate* III. *fig.* 2.) are single, and go over the yard-arm with an eye; the other end reeves through

through a thimble in the top-gallant ſhrouds, leads down into the top, and belays round the dead-eyes.

Clue-line-blocks, 2, (*Plate* II. *fig.* 19.) are ſtrapped with two laſhing-eyes, and laſh upon the yard three feet without the ſlings. The clue-line reeves through the block which hangs under the yard, which is ſtopt with a knot till the ſail is bent. The leading-part comes down the maſt, and belays to the ſhroud-rack.

The *tye*, 3, (*Plate* II. *fig.* 19.) reeves through the ſheave-hole in the top-gallant-maſt hounds, and clinches round the yard at the ſlings; in the lower end is turned a double or ſingle block, according to the ſize of the ſhip, through which reeves the haliard, and through a ſingle block laſhed to the after-part of the lower treſtle-trees, under the top, and belays round the croſs-piece of the bitts abaft the maſt.

Parral, the ſame as the topſail-yard, after the yard is ſwayed up.

Rigging of Royal-Yards.

When they have royal maſts, they rig as the top-gallant-yards above; but if there are no royal maſts, they ſet flying; that is, the *haliard* reeves through a ſheave-hole cloſe up under the truck; the ſtanding-part clinches to the middle of the yard, and the leading-part comes down and belays in the top.

Rigging of the Mizen-Yards.

Mizen-yards are now ſeldom uſed, and that only in line of battle ſhips in the navy, and large Eaſt India ſhips.

They are hove on board as the lower yards, and the

Derrick-block is ſtrapt with two eyes, that go round the yard and laſh underneath, between the ſlings and outer yard-arm or peek. The *Derrick-fall* reeves through the double block that is croſs-ſeized in the ſtrap, has an eye ſpliced in each end, and laſhes to the mizen-cap; then through the ſingle block upon the yard. The ſtanding-part is again taken up and reeved through the block at the mizen-cap; an eye is then ſpliced in the end to the ſize of the yard-arm, that jambs over the peek-end. The leading-part comes from the double block at the cap, leads down through the treſtle-trees to a block in the larboard, mizen channel, and through the ſide upon deck.

Brail-blocks are ſtrapt together in one ſtrap, and lie over the yard, and ſeized together underneath; the throat-blocks next the cleats near the maſt; the middle-blocks in the middle between the throat-blocks and the peeks; the peek-blocks about three or four feet within the cleats at the peek.

Vangs.—The pendants are doubled, and ſerved with ſpun-yarn two fathoms long in the bight, and a double block ſpliced in each end, and ſerved with ſpun-yarn over the ſplice in the houſe. The bight is put over the peek-end with a hitch. The falls reeve through the double block in their ends, and a ſingle block is hooked to an eye-bolt in the quarter-piece on each ſide. The ſtanding-part makes faſt to the becket of the ſingle block, and the leading-part from the double block, belays to a cleat on the taffrail.

Signal haliard-block is laſhed to an eye-bolt in the peek of the yard.

Jeers.—The fall reeves through a treble or double block laſhed at the maſt-head, and likewiſe a double or ſingle block laſhed between the ſling-cleats, and the leading-part comes into the mizen-chains on the ſtarboard ſide as the derrick did on the larboard ſide. The yard is then ſwayed up, and the fall made faſt with a hitch, and ſeized.

Slings go round the maſt-head, and round the yard between the ſling-cleats, which are kept abaft the maſt.

Bowlines reeve through a ſingle block ſtrapt with a thimble into an eye bolt, in the lower end of the yard, and through a block hooked to an eye-bolt in the ſide abreaſt the lower end of the yard, or laſhed to the mizen-ſhrouds.

Horſe for the mizen-ſheets clinches to an eye-bolt on each ſide the fore part of the taffrail with a thimble, to which is ſtrapped the ſheet-block.

Gaff.—If the mizen-yard is not uſed, there muſt be a *gaff*, 20, (*Plate* IV. *fig.* 1.) as in ſmaller veſſels, which is rigged ſimilarly to the mizen-yard, excepting only that it has a throat-haliard inſtead of jeers, which hooks to an eye-bolt over the jaws: and a ſpan inſtead of a derrick, 21, *Plate* IV. *fig.* 1.

The *driver* or *ſpanker-boom* rigs with a *topping-lift*, 25, (*Plate* IV. *fig.* 1.) which goes over the outer end of the boom with a clove-hitch, and ſtops againſt the ſhoulder; the ends are reeved through a ſingle block laſhed on each ſide of the mizen-maſt-head; then have a double block ſpliced in each lower end, which reeves with its fall to a ſingle block, hooked to an eye-bolt in each mizen-channel. The ſtanding-part makes faſt to the becket of the ſingle block, and the leading-part belays to a cleat on each ſide of the mizen-maſt.

Guy-pendants, 26, (*Plate* IV. *fig.* 1.) have a hook and thimble ſpliced in one end, that hook to a thimble on each ſide of a ſtrap ſpliced round the boom, over the horſe at the fore-ſide of the taffrail; a thimble is ſpliced in the inner ends of the pendants, to which is hooked the tackle on each ſide, that are uſed where moſt ſupport can be given to the boom.

Rigging and Bending the Sails.

Rigging and bending the fore-courſe, 5, (*Plate* IV. *fig.* 2.) This ſail is hoiſted on board by the yard-tackles, and laid athwart the main-ſtay, ready for bending, thus; the *ſheet-block* is ſtrapped with an eye, and put over the clue on each ſide. The tack is next thruſt through the clue for the knot to come on the aftſide.

Clue-garnet Block.—The eyes of the ſtrap are put through the clue, brought up on each ſide, and ſeized on the top.

Tacks are cable-laid, and tapered in the making. The biggeſt end is opened out long enough to heave the knot cloſe together; the knot is double-walled and crowned; the ends are thruſt through the walling, then ſcraped down, ſerved over with ſpun-yarn, and are wormed, parcelled, and ſerved with ſpun-yarn one-fourth of the whole length, in the houſe. (*Plate* I. *fig.* 14.) *Single tacks*, as the above, reeve through the block laſhed round the outer end of the boomkin, on each ſide; then lead in upon the fore-caſtle or upper deck, and belay round a large cleat upon the cat-tail, or the bitts near the maſt. In *double tacks*, the ſtanding-part makes faſt round the outer end of the boomkin, and the leading-part reeves through a ſingle block laſhed to the clue of the ſail, then through the block at the outer end of the boomkin, and leads in as the above, 21, *Plate* IV. *fig.* 2.

Sheets, 23, (*Plate* IV. *fig.* 2.) are reeved through the ſheet-block at the clues, and the ſtanding-part ſeizes or ſplices with a thimble to an eye-bolt in the ſide a little before the gangway. The leading-part reeves through a ſheave in the ſide above the eye-bolt, leads forwards, and belays round a large cleat in the ſide.

Yard-ropes are temporary, and are only uſed to get up the ſail; they reeve through tail-blocks, that are made faſt round the boom-iron at each yard-arm, and one end comes down

down and makes faſt to the upper reef-earing cringle. The leading-part comes in upon deck, through a leading-block laſhed to a timber-head or eye-bolt. The ſail is then run up to the yard, where the men go and paſs the

Earings: one end of the earing ſplices to the head-cringle with a long-eye; the other end paſſes over the yard-arm, without the rigging, and through the cringle alternately, two or three times, and likewiſe paſſes round the yard, within the rigging, and through the cringle, till the earing is expended, making faſt the end with two half-hitches. The outer turns are to ſtretch the head of the ſail tight along the yard, and the inner turns to draw it cloſe up.

Reef-earings, when uſed, the ſame.

Rope-bands, which faſten the head of the ſail along the yard, are braided cordage, with an eye in one end, and one leg longer than the other. The eye of the long leg is put over the ſhort leg, and the eye of the ſhort leg is thruſt through the eye-let hole at the aftſide of the ſail, and paſſes through the eye of the ſhort leg; and ſo of the reſt. The rope-bands, being previouſly reeved through the head of the ſail, faſten to the yard as follows. The long leg comes over the yard from the foreſide, with a round turn between the head of the ſail; the ſhort leg comes up the aftſide, and makes faſt with a reef-knot upon the yard. The ſail is then let fall to ſee it is clearly bent.

Points are uſually put in the ſail at the ſail-loft. See SAIL-*Making*.

Gaſkets are braided cordage, which go round the yard with a running-eye, two on each quarter, and one at each yard-arm: the bunt-gaſket in the middle has two legs, and laſhes to the yard on each ſide of the quarter-blocks. Theſe are uſed when the ſail is *furled,* to bind it firmly up to the yard, by paſſing the gaſket ſix or ſeven times round the yard and ſail, each turn a certain diſtance apart, or ſpirally, making faſt the end with two half-hitches.

Clue-garnets, 24, (*Plate* IV. *fig.* 2.) reeve through their block upon the yard on each ſide, then through the block at the clue of the ſail. The ſtanding-part is carried up, and made faſt round the yard by its block with a timber-hitch, and the end ſtopped. The leading-part comes down upon deck, and reeves through its ſheave-hole in the topſail-ſheet-bitts, and there belays.

Bowlines, 25, (*Plate* IV. *fig.* 2.) reeve through a ſingle block laſhed round the collar of the fore-ſtay, or the fore-preventer-ſtay on the bowſprit, and the outer part reeves on the bowline-bridle, with a thimble ſpliced in the end, and the bridle clinches to the cringle on the leech of the ſail. The leading-part comes in upon the forecaſtle, and belays to the fore-topſail-ſheet-bitts.

Leech-lines, 26, (*Plate* IV. *fig.* 2.) reeve through the ſpritſail-brace-block, under the top, then through the block upon the yard, and the ſtanding-part makes faſt with a clinch to the upper bowline-bridle; the leading-part then reeves through a double block, at the aft-part of the top, and comes down upon the forecaſtle.

Bunt-lines, 27, (*Plate* IV. *fig.* 2.) reeve through the leg and fall-block, and through a double block at the aft-part of the top, and through the blocks upon the yard, and lead down the fore-ſide of the ſail, and clinch to the cringles in the foot. The fall reeves through the leg-block; the ſtanding-part makes faſt to an eye-bolt near the maſt, and the leading-part through a live-block under the croſs-piece of the breaſt-bitts.

Slab-lines, 28, (*Plate* IV. *fig.* 2.) reeve through a ſmall block laſhed to the ſtrap of the quarter-block, and the ſtanding-part clinches with two legs to the middle bunt-line cringles. The leading-part leads to the topſail-ſheet-bitts, and belays to the croſs-piece.

Spilling-lines, 29, (*Plate* IV. *fig.* 2.) reeve through blocks laſhed on each ſide of the quarter-blocks of the lower yards, then lead down before the ſail, return upwards under the foot of the ſail, and make faſt round the yard with a timber-hitch.

Life-lines are ſometimes uſed for the preſervation of the ſeamen. They are generally of worn hawſer-laid rope, and are made faſt with the two half-hitches round the ſtrap of the lift-block, and jeer or tye-block, in the middle of the yard.

Rigging and Bending the Main-Courſe, 1, *Plate* IV. *fig.* 2.

This ſail is hoiſted on board, and laid athwart, ready for bending, as the fore-courſe. Sheet-blocks, tacks, and clue-garnet-blocks, are fitted in the clues as the fore-courſe.

Tacks, ſingle, 31, (*Plate* IV. *fig.* 2.) reeve through the ſheave-hole in the cheſtree, on each ſide, and lead on board through a ſheave-hole in the ſide, and belay round a range-cleat in the waiſt.

Tacks, double, 32, (*Plate* IV. *fig.* 2.) The ſtanding-part clinches to an eye-bolt before the cheſtree, and the leading-part reeves through a ſingle block laſhed to the clue of the ſail; then leads in upon deck, through the cheſtree and ſheave-hole in the ſide, and belays as the above.

Sheets, 33, (*Plate* IV. *fig.* 2.) reeve through the ſheet-block at the clues. The ſtanding-part is ſeized to an eye-bolt with a thimble on the quarters; the leading-part comes on board through a ſheave-hole in the ſide, and belays to a range-cleat in the waiſt. The preſent cuſtom is for the leading-part of the ſheets to reeve through a block laſhed to the eye of an iron ſtay, projecting from the ſide, called a *ſpider,* and comes in upon deck through a port that has a roller fitted vertically at its aftſide.

Yard-ropes and *bending,* as the fore-courſe.

Earings, rope-bands, points, gaſkets, and *clue-garnets,* as the fore-courſe.

Bow-lines, 34, (*Plate* IV. *fig.* 2.) reeve through a double block, laſhed round the fore-maſt five feet above the fore-caſtle, and the outer part reeves upon the long leg with a thimble. The lower bridle is the longeſt, and clinches to the lower cringle on the ſail. In the other end is ſpliced a thimble, through which reeves the upper leg, that clinches to the upper cringle. The ſtarboard bow-line belays on the larboard, and the larboard bow-line leads over and belays on the ſtarboard ſide. Four feet from the bridle on each bow-line is ſpliced a thimble, and pointed over, called a *lizard,* to which is hooked a bow-line tackle that makes faſt to the bitts, and is bowſed upon until the bow-line can be made faſt to the bitts.

Leech-lines, 35, (*Plate* IV. *fig.* 2.) reeve through the block upon the yard, and the outer end makes faſt with a clinch to the upper bow-line bridle. The leading-part reeves through a double block at the fore part of the top, and another at the aft part of the top. A ſingle block is turned into the lower end, and a whip-fall reeved through it. The ſtanding-part makes faſt to an eye-bolt in the deck; and the leading-part reeves through a block under the croſs-piece of the bitts, near the maſt.

Bunt-lines, 36, reeve as the fore-courſe, and lead forward upon the forecaſtle.

Slab-lines, 37, *ſpilling-lines,* 38, and *life-lines,* 39, (*Plate* IV. *fig.* 2.) as the fore-courſe.

Rigging and Bending the Mizen-Courſe, 9, *Plate* IV. *fig.* 2.

Earing reeves, with an eye in one end, through the cringle in the peek of the ſail, and makes faſt round the peek as the earings above.

The nock-earings the ſame as the peek.

Lacing is ſpliced to the peek-earing-cringle, and laces round the yard or gaff, through the eye-let holes in the head of the ſail, and makes faſt to the nock-earing-cringle. Lacing round the maſt is ſpliced to the nock-cringle, and round the fore-ſide of the maſt, backwards and forwards, and through each cringle on the fore-leech of the ſail, making faſt to the tack at the lower end.

Tack ſets up with a laniard reeved through the tack-cringle in the foot of the ſail, and through an eye-bolt in the deck.

Sheet reeves through a block on the horſe, at the fore part of the taffrail; then through the block that hooks to the thimble, in the clue of the ſail; again through the block on the horſe, and belays to a cleat on the ſide.

Brails, 41, (*Plate* IV. *fig.* 2.) throat, middle, and peek, reeve through their reſpective blocks on the yard or gaff, and make faſt to cringles on the after-leech of the ſail on each ſide. The throat-brails lead down by the maſt, and the middle brails lead down to the after-mizen-ſhroud on each ſide, and the peek-brails to a cleat on each quarter.

Fancy-line, 42, (*Plate* IV. *fig.* 2.) has two ſpans, with a thimble ſeized in the bight, and a thimble ſeized in each end; one thimble reeves upon the throat-brail, the other on the middle brail, on each ſide the ſail. The fancy-line reeves through blocks laſhed at the peek end, and each end bends to the thimble in the bight of the ſpan on each ſide. When the mizen is ſet, the brails are hauled up by the fancy-line, that they may be ſlack, and not girt the lee-ſide of the ſail.

Rigging and Bending the Topſails.

The *fore-topſail*, 6, (*Plate* IV. *fig.* 2.) is ſwayed up into the top by the topſail-haliards, that make faſt to ſlings round the middle of the ſail, and then laid in the fore part of the top fair for bending.

Sheets, 44, (*Plate* IV. *fig.* 2.) are paſſed through the fore part of the clue of the ſail, and ſtopt with an overhand-knot. They reeve through the ſhoulder-block at the lower yard, then through the quarter-block, and come down before the maſt; reeve through the ſheave-holes in the bitts, and there belay.

Clue-lines, 45, (*Plate* IV. *fig.* 2.) The ſtraps of the blocks are paſſed through the clues of the ſail, and brought round the clue to the fore part, and ſecurely ſeized. The clue-lines are paſſed the ſame as the clue-garnets of the courſes, and ſometimes have no block, but bend to the clue of the ſail.

Bow-lines, 46, (*Plate* IV. *fig.* 2.) reeve through the blocks at the bowſprit-cap. The outer part reeves on the lower bow-line bridle with a thimble, as the main-courſe. The leading-part comes in upon the forecaſtle, and belays to the topſail-ſheet-bitts.

Bunt-lines, 47, (*Plate* IV. *fig.* 2.) reeve through the block upon the yard, lead down on the fore-ſide of the ſail, and clinch to the cringles in the foot-rope. The leading-part reeves through a ſingle block, laſhed cloſe under the topmaſt croſs-trees, leads down through the ſquare hole in the top, and belays to the ſhrouds.

Reef-tackle-pendants, 48, (*Plate* IV. *fig.* 2.) reeve through the upper ſheave in the ſiſter-block in the topmaſt-ſhrouds, then through the ſheave-hole in the yard-arm, and clinch to the reef-cringle in the leech-rope of the ſail.

Reef-earings reeve through their bights in each reef-cringle, and are ſtopt to the next cringles and the head of the ſail, till uſed.

Spilling-lines have two legs, which are each made faſt with a timber-hitch round the quarters of the topſail-yard, then lead down on the aftſide, return upwards under the foot of the ſail, and reeve through a block on the fore-ſide, laſhed to the tye-block on the yard, then lead down upon deck abaft the maſt.

Life-lines, *earings*, *rope-bands*, and *points*, as the fore-courſe.

Gaſkets.—The yard-arm gaſket reeves with an eye round the yard-arm, within the cleats. Quarter-gaſkets reeve as the above, between the yard-arm and ſlings. Bunt-gaſkets have two legs, and laſh to the yard with an eye on each ſide the tye-block, and faſten thereto, when the ſail is hauled up in the bunt.

The Main-topsail, 2, (*Plate* IV. *fig.* 2.) is ſwayed up into the top, as the fore-topſail.

Sheets, 51, *clue-lines*, 52, *bunt-lines*, 53, *reef-tackle pendants*, 54, *earings*, *rope-bands*, *points*, and *gaſkets*, as the fore-topſail.

Bow-lines reeve through blocks laſhed round the fore-maſt-head, cloſe under the cap; the outer part reeves on the lower bowline-bridle with a thimble, as the fore-topſail. The leading-part comes down through the ſquare hole of the cap, reeves through a ſheave-hole in the bitts upon the forecaſtle, and there belays.

The Mizen-topsail, 10, (*Plate* IV. *fig.* 2.) in large ſhips, is ſwayed as the foregoing.

Sheets, 56, *clue-lines*, 57, *bunt-lines*, 58, *reef-tackle pendants*, 59, *earings*, *rope-bands*, *points*, and *gaſkets*, as the fore-topſail.

Bow-lines, 60, (*Plate* IV. *fig.* 2.) bend to the ſail as the fore-topſail, and reeve through a ſingle block, ſeized to the main-ſhrouds on the oppoſite ſide near the futtock-ſtaff; then lead down through a ſeizing-truck to the quarter-deck, and belay to the rack at the ſhrouds.

Rigging and Bending the Top-gallant Sails.

The Fore-top-gallant-sail, 7, (*Plate* IV. *fig.* 2.) is either ſwayed up to the topmaſt croſs-trees by the clue-lines, or bent to the yard upon deck. It is hauled out to the yard-arm by earings, and bends or laces to the yard, as before obſerved.

Sheets, 62, and *clue-lines*, 63, are bent to the clues of the ſail, and lead down upon deck, as the fore-topſail.

Bunt-lines, 64, reeve through a ſmall block, ſeized to the top-gallant-maſt-head; then through a thimble ſeized to the tye, cloſe down upon the yard, and bend, with legs, to cringles in the foot of the ſail. The leading-part comes down into the top.

Bow-lines, 65, (*Plate* IV. *fig.* 2.) reeve through the thimbles at the jib-boom-end, and faſten to the ſail as the topſail, only with a toggle, to caſt off the bow-line readily for ſending the yard down. The leading-part comes down the forecaſtle, and belays to a pin in the hook over the bowſprit.

The jack-block is ſtrapped with a ſeizing-eye, through which reeves a ſhort piece of rope, with an eye ſpliced in one end, and a double walnut-knot made at the end, called a button and loop, which encircles the maſt, by thruſting the knot through the eye, and is triced up and down the maſt by the top-gallant-tye, which bends through the eye

of

of the ſtrap. It is uſed for ſending the top-gallant-yards up or down. When the yard is ſwayed up, the top-rope reeves through the jack-block, and makes faſt with a hitch round the yard in the ſlings, then ſtopt at the outer quarter to the eye-bolt in the yard-arm. When lowered, the ſame, except the ſtop at the eye-bolt. The rigging is taken off or put on by the men at the maſt-head, when the yards are ſwayed up or lowered down.

The MAIN-TOP-GALLANT-SAIL, 3, (*Plate* IV. *fig.* 2.) rigs and bends as the former. Bow-lines, 67, reeve through the ſheave-holes in the after-ends of the fore-topmaſt croſs-trees, and lead down upon deck. *Sheets*, 68, *clue-lines*, 69, *bunt-lines*, 70, *Plate* II. *fig.* 2.

The MIZEN-TOP-GALLANT-SAIL, 11, rigs and bends as the former. Bow-lines, 72, reeve through the ſheave-holes in the after-end of the main-topmaſt croſs-trees.

Rigging and Bending the Royals.

Royals, fore, 8, main, 4, and mizen, 12, (*Plate* IV. *fig.* 2.) are ſet flying; the clues laſhed to the top-gallant yard-arms.

When royal maſts are uſed, the royals rig ſimilar to top-gallant ſails.

Rigging and Bending the Jib and Stayſails.

Jib, 7, (*Plate* IV. *fig.* 1.) bends to its ſtay with hank and ſeizings.

Stay, 57, reeves through the upper ſheave of the cheek-block at the fore-topmaſt-head, from aft on the ſtarboard ſide, then through the hanks, and clinches to the traveller on the boom; a double block is then turned in the lower end, and its fall reeves through it; and a ſingle block, laſhed to the after-end of the fore-maſt treſtle-trees, leads down upon deck, and belays to the bitts abaft the fore-maſt.

Haliards, 58, reeve through the lower ſheave of the cheek-block at the fore-topmaſt-head, from aft on the ſtarboard ſide, and bend to the head of the ſail. The leading-part leads abaft the top to the aft part of the forecaſtle. Large ſhips have a ſingle block turned into the lower end of the haliards, and a whip-fall; the ſtanding-part makes faſt into the ſide.

Sheets, 59.—The bight is bent to the clue of the ſail, and a ſingle block turned in each inner end, that reeves a whip-fall. The ſtanding-part makes into the ſide, and the leading-part leads in upon the forecaſtle, and belays to a timber-head, or a cleat before the ſhrouds on each ſide.

Downhauler, 60, reeves through a ſmall block laſhed to the traveller, then leads upwards through the hanks, and bends to the head of the jib. The leading-part leads in upon the forecaſtle.

Outhauler reeves through a ſheave-hole at the outer end of the jib-boom, and clinches to the ſpan-ſhackle of the traveller. The inner end has a double block turned in, which reeves with its fall to a ſingle block, hooked to an eye-bolt in the fore part of the bowſprit-cap, and the fall leads in on the forecaſtle.

Inhauler reeves through a ſmall block laſhed on the traveller. The ſtanding-part makes faſt to an eye-bolt in the ſide of the bowſprit-cap, and the leading-part comes in upon the forecaſtle.

The FORE-TOPMAST-STAYSAIL, 6, (*Plate* IV. *fig.* 2.) bends to its ſtay with hanks and ſeizings. *Stay*, 62, reeves through the hanks, then makes faſt with a running-eye round the bowſprit, between the collars and the ſpritſail-yard; then reeves through the upper ſheave of the cheek-block, at the fore-topmaſt-head, on the larboard ſide; the lower end has a double block turned in, and reeves with its fall to a ſingle block laſhed at the after-end of the fore-maſt treſtle-trees, leads upon deck, and belays to the bitts abaft the fore-maſt.

Haliards, 63, reeve through the lower ſheave of the cheek-block at the fore-topmaſt-head, on the larboard ſide, and bend to the head of the ſail. The leading-part leads down abaft the top to the after-part of the forecaſtle, and belays to a cleat in the ſide.

Sheets, 64.—The bight is bent to the clue of the ſail, and leads through a ſingle block, laſhed to an eye-bolt on each ſide of the forecaſtle.

Downhauler, 65, reeves through a ſmall block that laſhes at the tack of the ſail, then leads up through the hanks, and bends to the head of the ſail; and the leading-part comes in upon the forecaſtle.

Outhauler reeves through a block laſhed at the outer end of the bowſprit; the ſtanding-part makes faſt to the tack of the ſail, and the leading-part comes in upon the forecaſtle.

FORE-STAYSAIL, 5, (*Plate* IV. *fig.* 1.) bends to the preventer-ſtay with hanks and ſeizings.

Haliards, 67, reeve through a ſingle block bent to the head of the ſail. The ſtanding-part makes faſt round the head of the fore-maſt; and the leading-part reeves through a block laſhed to the rigging under the top, and leads down abaft the maſt.

Sheets, 68, are doubled, and the bight put through the clue of the ſail; and a ſingle block ſpliced in each end. The ſtanding-part of the fall is made faſt round a timber-head on the forecaſtle or eye-bolt, and the leading-part comes in through a block made faſt to the ſaid eye-bolt.

Tack, 69, bends to the tack of the ſail, and laſhes the tack of the ſail to the ſtay near the heart.

Downhauler, 70, reeves up through the hanks, bends to the head of the ſail, and leads in upon the forecaſtle through a ſingle block laſhed near the tack.

MAIN-STAYSAIL, 1, (*Plate* IV. *fig.* 1.) is ſeldom bent in ſhips but at ſea, though commonly in brigs. It bends to the main-ſtayſail ſtay with hanks and ſeizings.

Stay, 72, has its upper end clinched round the main-maſt-head above the rigging, and the lower end ſet up with a luff-tackle round the foremaſt.

Haliards, 73, reeve through a ſingle block laſhed to the head of the ſail. The ſtanding-part makes faſt at the main-maſt-head, and the leading-part reeves through a block laſhed to the rigging under the top, and leads down abaft the maſt: a double block is turned in to the end, and connected, by its fall, to a ſingle block, hooked to an eye-bolt in the ſide abaft the maſt.

Sheets, 74, are doubled, the bight is put through the clue of the ſail, and the ends through the bight. A block is ſpliced into each end, and the ſtanding-part of each fall makes faſt on its reſpective ſide at the fore part of the quarter-deck, and the leading-part through a ſnatch-block. Sometimes a luff-tackle is clapt on to bowſe the ſheets aft.

Tacks, 75, bend to the tack of the ſail, and laſh the tack of the ſail to the foremaſt, or the bitts abaft it.

Downhauler, 76, reeves up through the hanks, bends to the head of the ſail, and belays to the main-top bow-line bitts.

MAIN-TOPMAST-STAYSAIL, 2, (*Plate* IV. *fig.* 1.) bends to the main-topmaſt preventer-ſtay with hanks and ſeizings.

Haliards, 78, reeve from the aftſide through the cheek-block at the main-topmaſt-head on the larboard ſide, come

down

down and bend to the head of the ſail. The leading-part reeves through a block in the ſide.

Sheets, 79, are doubled, the bight is put through the clue of the ſail, and the ends through the bight. A block is ſpliced in each end, and the ſtanding-part of each fall makes faſt on its reſpective ſide to the boat-ſkid beam next before the quarter-deck, and the leading-parts reeve through a block on the gunwale abaft the gangway, and belays to a pin in the boat-ſkid beam.

Tacks, 80, are doubled, the bight is put through the tack of the ſail, and the ends reeve through the bight, and lead through a thimble ſeized to the lower ſhrouds on each ſide; they lead down and belay to a ſhroud-cleat.

Brails, 81, reeve through blocks laſhed to the ſtrap of the main-bowline-block, and through blocks ſeized to the topmaſt preventer-ſtay, at the cat-harpins on each ſide, and then make faſt on each ſide the ſail to a cringle on the after-leech.

Sheets, 82, are doubled, the bight is put through the clue of the ſail, and the ends through the bight. A block is ſpliced in each end, and the ſtanding-part of each fall is made faſt on its reſpective ſide to the boat-ſkid beam next the quarter-deck, and the leading-part reeves through a block on the gunwale on each ſide abaft the gangway.

Tacks, 83, are doubled, the bight is put through the tack of the ſail, and the ends through the bight, and lead through a thimble ſeized on the lower ſhrouds on each ſide; they then lead down and belay to one of the ſhroud-cleats.

MIDDLE-STAYSAIL, 3, (*Plate* IV. *fig.* 1.) bends to the middle-ſtayſail-ſtay with hanks and ſeizings.

Stay, 85. The ſtanding-part reeves through the hanks, and makes faſt to a thimble ſeized in a ſtrap or grommet made faſt round the fore-topmaſt-head, below the parral. The leading-part reeves through the upper ſheave-hole at the main-topmaſt-head: a double block is then turned into the end, and connects by its fall with a ſingle block, that laſhes to the main-treſtle-trees, and the fall by which it is ſet up leads upon deck abaft the maſt.

Haliards, 86, reeve through the lower ſheave of the cheek-block at the main-topmaſt-head, and bend to the head of the ſail; the other end leads upon deck abaft the maſt.

Sheets, 87, are doubled, the bight is put through the clue of the ſail, and the ends through the bight, and lead down through a block on each ſide near the gangway.

Tacks, 88, are doubled, the bight is put through the tack of the ſail, and the ends through the bight, and each end through a thimble ſeized in the fore-topmaſt-ſhrouds, and belays in the top.

Downhauler, 89, reeves through a ſingle block ſeized to the ſtay at the nock of the ſail, then leads up through the hanks, and bends to the head of the ſail, and the lower end comes down upon deck abaft the maſt.

Tricing-line clinches to the grommet round the fore-topmaſt, and reeves through a block under the fore-topmaſt-croſs-trees, and leads down into the top.

MAIN-TOP-GALLANT-STAYSAIL, 4, (*Plate* IV. *fig.* 1.) bends to the ſtay, or main-top-gallant-ſtay, in ſmall ſhips, with hanks and ſeizings.

Stay, 91. The upper end ſplices into the top-gallant-ſtay below the rigging, and the lower end reeves through a thimble ſeized to the fore-topmaſt-croſs-trees, leading down into the top.

Haliards, 92, reeve through a ſheave-hole above the hounds of the main-top-gallant-maſt, and bend to the head of the ſail; the leading-part comes down upon deck, and belays to the bitts abaft the main-maſt.

Sheets, 92, and *tacks*, 93, as the middle ſtayſail.

Downhauler, 94, reeves up through the hanks, and bends to the head of the ſail; and the leading-part comes upon deck abaft the fore-maſt.

MIZEN-STAYSAIL, 8, (*Plate* IV. *fig.* 1.) bends to the mizen-ſtayſail ſtay with hanks and ſeizings.

Stay, 96, hitches round the head of the mizen-maſt, then reeves through a thimble ſeized in a collar laſhed round the main-maſt, and ſets up with a laniard through a thimble turned in to the ſtay, and an eye-bolt in the deck abaft the maſt.

Haliards, 97, reeve through a block at the head of the ſail, the ſtanding-part makes faſt round the mizen-maſt-head, and the leading-part reeves through a block laſhed to the treſtle-trees, and through a block in the ſide at the deck.

Sheets, 98, bend to the clue of the ſail with a long and ſhort leg, having a thimble ſpliced in the latter. The long leg reeves through a block in the ſide, and through the thimble in the ſhort leg, and belays to the rack at the ſide.

Tack, 99, ſplices to the tack of the ſail, and laſhes it to an eye-bolt in the deck abaft the mizen-maſt.

Downhauler, 100, reeves through a block made faſt to the collar of the ſtay, then upwards through the hanks, and bends to the head of the ſail, and belays to the fore-brace bitts.

Brails, 101, reeve through blocks laſhed on each ſide the collar, then through thimbles in a ſtrap put through the ſail, and make faſt to a cringle on the after-leech. The leading-part belays a-breaſt of the quarter-deck.

MIZEN-TOPMAST-STAYSAIL, 9, (*Plate* IV. *fig.* 1.) bends to the mizen-topmaſt-ſtay with hanks and ſeizings.

Haliards, 103, reeve through the ſheave-hole in the top-maſt above the rigging, or through a block laſhed round the maſt-head; one end bends to the head of the ſail, the lower end leads down upon deck abaft the maſt.

Sheets, 104, are doubled, the bight put through the clue of the ſail, and the ends through the bight; then through a thimble ſeized in the mizen-ſhrouds on each ſide, and lead down and belay to a pin in the ſhroud-rack.

Tacks, 105, are doubled, the bight put through the tack of the ſail, and the ends through the bight, then through a thimble ſeized to the main-topmaſt-ſhrouds on each ſide, and lead down and belay in the top.

Downhauler, 106, reeves up through the hanks, and bends to the head of the ſail; the lower end leads down upon deck, and belays at the fore part of the quarter-deck.

MIZEN-TOP-GALLANT-STAYSAIL, 10, (*Plate* IV. *fig.* 1.) bends to the mizen-top-gallant-ſtay with hanks and ſeizings.

Haliard, 108, reeves through the ſheave-hole above its top-gallant-maſt hounds; one end bends to the head of the ſail, the lower end leads down upon deck abaft the maſt.

Sheets, 109, are doubled, the bight put through the clue of the ſail, and the ends through the bight, and lead down upon deck through a thimble ſeized in the mizen-ſhrouds, on each ſide near the cat-harpins, and belay to a pin in the ſhroud-rack.

Tacks, 110, bend to the tack of the ſail as the ſheets, and lead down into the top through a thimble ſeized in the main-topmaſt-ſhrouds on each ſide.

Downhauler, 111, reeves up through the hanks, and bends to the head of the ſail, the lower end comes into the main-top, and belays to the top-rail.

Rigging

Rigging and Bending the Studding-Sails.

Studding-ſails bend their yards at the head with rope-bands, the ſame as other ſquare ſails.

Lower ſtudding-ſails, main, 15, (*Plate* IV. *fig.* 2.) *Outer haliards,* 61, reeve through a ſpan-block hitched round the lower cap, and through a block at the lower yard-arm or boom-iron, and bend between the cleats of the ſtudding-ſail-yard; the other end leads down upon deck.

Inner haliards, 62, bend to the upper inner cringle on the head of the ſail, then reeve through a tail-block made faſt round the quarter of the lower yard, then through another block made faſt round the yard near the maſt, and lead down upon deck.

Sheets, 63, are doubled, the bight is put over, and the ends through the inner clue on the foot of the ſail; one leads forward, and the other aft.

Fore-ſtudding-ſail, 18, (*Plate* IV. *fig.* 2.) ſets flying, or with a boom at the foot. If flying, the foot of the ſail ſpreads on a yard, that rigs with a ſpan clinched round each yard-arm. A guy is bent to an eye that is croſſed in the middle of the ſpan, and leads aft through a block laſhed to the main-chains, leads in through a port, and belays round a cleat in the waiſt. The ſail thus rigged has no tacks. Booms rig as follow: the hook in the inner end hooks to an eye-bolt between the fore-chains and cat-head, and the hook of the main-ſtudding-ſail-boom in an eye of an iron ſtrap on the fore part of the main channel; the end is confined down with a laſhing to the chain-plates; the inner end of the fore-boom is confined down with a tackle, made faſt round the inner end of the boom, and the lower block is hooked to an eye-bolt in the wale; the guy clinches round the middle of the boom, reeves through a block laſhed round the ſpritſail-yard, and leads in upon the forecaſtle.

Topmast-studding-sails, *Main,* 16, *Fore,* 19, (*Pl.* IV. *fig.* 2.) *Haliards,* 90, 91, reeve through a block in the ſpan round the topmaſt-head, under the cap, and through the jewel-block, at the outer end of the top-ſail-yard-arm, and bend to the topmaſt-ſtudding-ſail-yard; the other end leads down upon deck, and belays to the bitts next the maſt.

Sheets are doubled, the bight is put through the inner clue, and the ends through the bight. The after-ſheet, 92, of the fore-topmaſt-ſtudding-ſail leads in abaft the fore-ſhrouds, and the fore-ſheet, 93, leads in upon the forecaſtle. The after-ſheet, 94, of the main-topmaſt-ſtudding-ſail leads down to the quarter-deck, and the fore-ſheet, 95, upon the gangway.

Tacks, 73, bend to the outer clue of the ſail, reeve through a block laſhed to the outer end of the boom, and lead aft through a block at the gangway. Tack, 74, of the main-topmaſt-ſtudding-ſail leads in upon the after-part of the quarter-deck through a block laſhed upon the quarter.

Downhauler, 75, reeves through a block laſhed to the outer clue of the ſail, and through a thimble on the outer leech: it is then made faſt to the topmaſt-ſtudding-ſail-yard, juſt within the earing, and leads into the waiſt.

The Booms, 76, 77, are run out by the tackles. The ſtrap of the double-block makes faſt through a hole in the heel of the boom, and the outer block to the boom-iron, and the fall leads along the yard. On the middle of the boom is faſtened a ſelvagee, or a ſtrap with a thimble, to which is hooked the top-burton-tackle, to ſupport the boom in the middle.

Top-gallant-studding-sails; fore, 20, main, 17, (*Plate* IV. *fig.* 2.) *Haliard* reeves through a block ſeized round the head of the top-gallant-maſt, above the hounds or rigging, then through the jewel-block, ſtrapt with a thimble through an eye-bolt at the ends of the top-gallant-yards, and bends to the top-gallant-ſtudding-ſail-yard; the other end leads down the maſt into the top.

Sheets, 80, are doubled, the bight is put through the lower inner clue of the ſail, and the ends through the bight; one end leads forward, and makes faſt to the quarter of the topſail-yard, and the other end leads into the top, and belays to the topmaſt-ſhrouds.

Tacks, 81, bend to the outer clue of the ſail, and reeve through a thimble in a ſtrap round the outer end of the top-maſt-ſtudding-ſail-boom; and in merchant ſhips that have no boom, through a thimble in a ſtrap round the outer yard-arm of the topmaſt-ſtudding-ſail. The fore-top-gallant-ſtudding-ſail-tack leads aft to the main-chains, and the main leads to the quarter-piece.

Downhauler, 82, makes faſt to the outer yard-arm within the earing, and leads down into the top.

Rigging and Bending the Spritſail-Courſe.

The ſpritſail-courſe, 13, (*Plate* IV. *fig.* 2.) bends to its yard as the fore-courſe.

Sheets, double, 84, reeve through a block ſeized to the clue of the ſail; the ſtanding-part clinches to an eye-bolt in the bow, and the leading-part comes in on the forecaſtle.

Sheets, ſingle, bend to the clue of the ſail, and lead in-board.

Clue-lines, 85, reeve through the blocks upon the yard, and bend or reeve through a block at the clue of the ſail, and lead in upon the forecaſtle.

Bunt-lines, double, 86, reeve through the block on the yard, and clinch to the cringles at the foot of the ſail, and lead in upon the forecaſtle.

Bunt-lines, ſingle, reeve through a block in the ſlings of the yard, and clinch with legs to the cringles in the foot of the ſail, and lead in upon the forecaſtle.

Rigging and Bending the Spritſail-Topſail.

The ſpritſail-topſail, 14, (*Plate* IV. *fig.* 2.) bends to the yard with lacing and earings.

Sheets, 88, reeve through the ſheet-block at the ſpritſail-yard-arm, and hook to the clue of the ſail, and lead in upon the forecaſtle, through a block laſhed on each ſide of the bowſprit.

Clue-lines, 89, the ſame as the ſpritſail.

Rigging and Bending the Driver or Spanker-ſail, 11, *Plate* IV. *fig.* 1.

This ſail is only uſed occaſionally, and is bent or hoiſted in a temporary manner, thus; it is made faſt at the peek, 113, and nock, 114, with an earing, as the mizen, and makes faſt to the yard and gaff with four or five pairs of haliards, that reeve through blocks made faſt with tails round the yard and gaff, one end of the haliard being bent to the head of the ſail. The throat-haliards, 115, reeve with a double and ſingle block: the former is made faſt round the maſt-head, and the latter hooks to the nock-cringle on the ſail.

Sheet, 116, reeves through a block or ſheave-hole at the outer end of the boom, and bends to the clue of the ſail; a luff-tackle is cat's-pawed to the other end of the ſheet; the inner block hooks to the taffarel, and the fall leads in upon the quarter-deck. When this ſail is bent to the maſt, yard, or gaff, inſtead of the mizen, it bends exactly the ſame, only the foot of the ſail is extended on the boom, as above.

Tack,

Tack, 117, is ſet tight with a luff-tackle, that hooks to the cringle in the tack of the ſail, and to an eye-bolt in the throat of the boom.

Downhauler, 118, reeves through a block made faſt to the middle of the driver-yard, and leads down to the taffarel.

Rigging of Snows, Brigs, &c.

A *Snow* has her ſails and rigging on the fore and main-maſt, ſimilar to thoſe on the ſame maſt in a ſhip. The braces of the yards on the main-maſt lead forward. The tryſail abaft the main-maſt bends to the tryſail-maſt, ſimilar to the mizen of a ſhip.

Veſſels in the navy reſembling ſnows have a rope-horſe, that ſets up abaft the main-maſt, with dead-eyes and a laniard, to an eye-bolt in the deck, to which the tryſail is bent by hanks and ſeizings, ſimilar to the tryſail of a ſnow.

Brigs.—The rigging of a brig differs little from the fore and main-maſt of a ſhip; the braces of yards on the main-maſt lead forward. The after-main-ſhroud is ſerved from the maſt-head to the dead-eye, to prevent its being chafed by the main-boom and gaff. The after-backſtay is fitted with a tackle, that it may be ſlackened when the main-ſail jibes, or is bowſed forward by the boom-pendant and tackle.

Boom-topping-lift is taken up on the ſtarboard ſide, and reeved through an iron-bound block, hooked to the upper eye-bolt on the aftſide of the main-maſt-head, then leads down and reeves through a block at the after-end of the boom. The ſtanding-part clinches round the maſt-head, or hooks to an eye-bolt near the block; the leading-part comes down and has a double block ſpliced or turned in, that connects by its fall to a ſingle block that hooks to an eye-bolt in the after-part of the channel. Sometimes it has the addition of a runner.

Main-ſheet reeves through a double block, ſtrapped round the boom within the taffarel, and through another double block, ſtrapped round the horſe inſide the taffarel, and belays to a large cleat, or the pin in the ſheet-block of ſmall veſſels. Large veſſels ſometimes have a treble block on the horſe.

Tack-tackle has the double block faſtened to the tack of the ſail, and connects with its fall to a ſingle block hooked to an eye-bolt in the deck.

Guy-pendants have a hook and thimble, that hook in a thimble of a ſtrap on the boom, juſt without the main-ſheet-block. In the inner end of the pendant, is a thimble or long-eye ſpliced, to which is hooked a luff-tackle, which is hooked to an eye-bolt in the ſide before the maſt, and the fall leads in-board.

Gaff-topping-lift rigs ſimilar to the boom above, only it has a ſpan upon the gaff, and the block at the maſt-head hooks to the eye-bolt, next below the boom-topping-lift; and the

Haliard connects it to an eye-bolt in the deck or ſide, the ſame as the boom.

Inner tye is ſimilar to the above, and hooks to an eye-bolt in the jaws of the gaff, then reeves through an iron-bound block, that hooks to an eye-bolt in the maſt-head below the above. It has a double block ſpliced or turned in to the lower end, and ſets up by the haliards, the lower block hooking to an eye-bolt on the oppoſite ſide to the tye above.

Peek-downhauler reeves through a ſmall block, ſtrapped with a thimble to the eye-bolt at the outer end of the gaff, and belays round a cleat under the boom.

Throat-downhauler reeves through a block at the nock of the ſail, and leads down the aftſide of the maſt.

Main-sail bends at the head to the gaff with lacing and earings, and is ſeized to the hoops round the maſt, through the holes in the fore-leech.

Throat-downhauler.—The double block hooks to an eye-bolt under the throat of the gaff, that connects by its fall to a ſingle block hooked to the thimble, ſeized in the bight of a ſtrap round the maſt under the boom ſaddle.

Sheet-rope ſplices in the clue of the ſail, and reeves through a ſheave-hole in the boom; and a thimble is turned in to the inner end, to which hooks the ſheet or luff-tackle, and the inner block to a ſtrap round the boom near the jaws. When the ſail is hove out, it is laſhed with an earing through the clue, and an eye-bolt in the boom-end.

Tricing-line reeves through a ſmall block made faſt to an eye-bolt in the throat of the gaff; one end ſplices to the tack of the ſail, the other end leads down upon deck, and belays to a cleat on the maſt.

Rigging of Cutters or Veſſels with one Maſt.

The different articles before the maſt rig ſimilar to ſhips, and the ſhrouds, boom, &c. as the brigs.

Gaff-topsail laces to a ſmall gaff at the head.

Haliards reeve through a ſheave-hole at the top-gallant-maſt-head, and bend to the inner quarter of the gaff; the leading-part comes down upon deck.

Topping-lift reeves through a ſheave-hole, or ſmall block, ſeized to the top-gallant-head, then through a thimble or ſmall block ſeized at the outer end of the gaff; the ſtanding-part clinches round the top-gallant-maſt-head above the ſheave-hole, and the leading-part comes down upon deck.

Sheet reeves through a thimble ſeized at the peek of the main-ſail, and bends to the clue of the ſail, and leads down upon deck.

Tack makes faſt to the tack of the ſail, a little above the rigging.

Saveall-topſail.—The clues laſh near the lift-block of the croſs-jack-yard.

Haliards bend to the earings of the ſail, and reeve through a block on each quarter of the topſail-yard, and lead down upon deck.

Ringtail-sail bends to a ſmall yard on the head, and is hoiſted by the peek-downhauler, abaft the main-ſail. The foot is expanded on a ſmall boom, or ſpar, laſhed to the outer end of the main-boom.

Water-sail bends on the head to a ſmall yard.

Haliards reeve through a ſmall block laſhed under the outer end of the main-boom, and make faſt to the middle of the yard, and the leading-part belays round a cleat on the taffarel.

Sheets make faſt to the clues of the ſail, and lead in over the quarters.

Mizen is ſet on a ſmall maſt over the ſtern. If a ſquare-ſail, it bends to a yard at the head, and is hoiſted by a *haliard* reeved through a ſheave-hole at its maſt-head, and is ſpread by *ſheets* at the foot. If a ſpritſail, its fore-leech bends to the maſt with grommets, and is ſpread or peeked with a ſprit, and the foot hauls aft by the ſheet to a ſmall boom.

Rigging, *Serving the.* See Rigging.

RIGHT, Rectum, in *Logic* and *Ethics*.

In this ſenſe the word ſtands oppoſed to *wrong*, *erroneous*, *falſe*, &c.

Right, in *Geometry*, ſomething that lies evenly, without inclining or bending one way or another.

Thus, a *right line* is that whoſe ſeveral points all tend the ſame way, or which lies evenly between its extremes.

In this sense, *right* signifies as much as *straight*, and stands opposed to *curved* or *crooked*.

Right *Angle*. See Angle.

In this sense, the word *right* stands opposed to *oblique*.

Right-*Angled* is understood of a figure, when its sides are at right angles, or stand perpendicularly one upon another.

This sometimes holds in all the angles of the figure, as in squares and rectangles; sometimes only in part, as in right-angled triangles.

Right *Cone*. See Cone.

Right-*Lined Angle*. See Angle.

Right *Sine*. See Sine. The word here stands contradistinguished to *versed*.

Right *Ascension*, in *Astronomy*. See Ascension.

Right *Ascension, Angle of*. See Angle.

Right *Ascension, Parallax of*. See Parallax.

Right *Descension*. See Descension.

Right *Descension, Parallax of*. See Parallax.

Right *Sphere* is that where the equator cuts the horizon at right angles: or, that in which the poles are in the horizon, and the equator is in the zenith.

Such is the position of the sphere with regard to those who live directly under the equator. The consequences of which position are, that they have no latitude, nor elevation of the pole. They can see nearly both poles of the world; all the stars rise, culminate, and set, with them; and the sun always rises and descends at right angles to their horizon, and makes their days and nights equal.

In a right sphere the horizon is a meridian; and, if the sphere be supposed to revolve, all the meridians successively become horizons, one after another.

Right *Circle*, in the *Stereographical Projection of the Sphere*, is a circle at right angles to the plane of projection, or that which passes through the eye. See Projection.

Right *Sailing* is when a voyage is performed on some one of the four cardinal points.

If a ship sail under the meridian, that is, on the north or south points, she varies not in longitude at all, but only changes the latitude, and that just so much as the number of degrees she has run.

If a ship sail under the equinoctial upon the very east or west points, she alters not her latitude at all, but only changes the longitude, and that just so much as the number of degrees she hath run.

If she sail directly east or west, under any parallel, she there also altereth not her latitude, but only the longitude; yet that not according to the number of degrees of the great circle she hath sailed in, as under the equinoctial, but more according as the parallel is remoter from the equinoctial towards the pole. For the less any parallel is, the greater is the difference of longitude.

Right, *Jus*, in *Law*, signifies not only a property, for which a writ of right lies, but also any title or claim, either by virtue of a condition, mortgage, or the like, for which no action is given by law, but only an entry.

Such are *jus proprietatis*, a right of property; *jus possessionis*, a right of possession; and *jus proprietatis et possessionis*, a right both of property and possession.

This last was formerly called *jus duplicatum*. As if a man be disseised of an acre of land, the disseisee has *jus proprietatis*; the disseisor hath *jus possessionis*; and, if the disseisee release to the disseisor, he hath *jus proprietatis et possessionis*. See Jus.

Right, *Hereditary*. See Hereditary.

Right, *Petition of*. See Petition.

Right, *Pretensed*. See Pretensed.

Right *of Reformation*. See Reformation.

Right, *Writ of*. See Writ and Recto.

Right *in Court*. See Rectus *in Curia*.

Right *Distillation*. See Distillation.

RIGHTING, in *Sea Language*, denotes the act of restoring a ship to her upright position, after she has been laid on a careen. This is generally the natural effect of casting loose the careening pullies, by which she had been drawn down. But it is sometimes necessary to apply mechanical powers to right the ship in such a situation; and the principal of these are the relieving tackles.

A ship is said also to right at sea, when she rises with her masts erected, after having been prest down on one side by the effort of her sails, or a heavy squall of wind. Falconer.

Righting, when expressed of the *helm*, implies the replacing it amidships, after it has been put over to the side in tacking or otherwise.

RIGHTS, *Bill of*, in *Law*, is a declaration, delivered by the lords and commons to the prince and princess of Orange, February, 13 1688; and afterwards enacted in parliament, when they became king and queen. This declaration sets forth, that king James II. did, by the assistance of divers evil counsellors, endeavour to subvert the laws and liberties of this kingdom, by exercising a power of dispensing with and suspending of laws; by levying money for the use of the crown, by pretence of prerogative, without consent of parliament; by prosecuting those who petitioned the king, and discouraging petitions; by raising and keeping a standing army, in time of peace; by violating the freedom of election of members to serve in parliament; by violent prosecutions in the court of king's bench; and causing partial and corrupt jurors to be returned on trials, excessive bail to be taken, excessive fines to be imposed, and cruel punishments inflicted; all which were declared to be illegal. And the declaration concludes in these remarkable words, "And they do claim, demand, and insist upon, all and singular the premises, as their undoubted rights and liberties." And the act of parliament itself (1 W. & M. stat. 2. cap. 2.) recognizes "all and singular the rights and liberties asserted and claimed in the said declaration to be the true, ancient, and indubitable rights of the people of this kingdom."

RIGIACUM, in *Ancient Geography*, a town of Belgic Gaul, and capital of the Attrebatii. Ptolemy.

RIGID Marble. See Marble.

RIGIDITY, among *Philosophers*, a brittle hardness; or that kind of hardness supposed to arise from the mutual indentation of the component particles within one another.

Rigidity is opposed to ductility, malleability, &c.

RIGLAND, in *Geography*, a town of Germany, in the margraviate of Anspach; 7 miles N. of Anspach.

RIGLET. See Reglet.

RIGNAC, in *Geography*, a town of France, in the department of the Aveyron, and chief place of a canton, in the district of Rodes; 12 miles W.N.W. of Rodes. The place contains 851, and the canton 7182 inhabitants, on a territory of $202\frac{1}{2}$ kiliometres, in 16 communes.

RIGNEY, a town of France, in the department of the Doubs; 10 miles N.E. of Besançon.

Rigney *le Seron*, a town of France, in the department of the Aube; 6 miles N.W. of Ervy. N. lat. 48° 12'. E. long. 3° 43'.

RIGNY, a town of France, in the department of the Indre and Loire; 6 miles N.N.E. of Chinon.

RIGO, a small island in the West Indies, near the N.W. coast of Porto Rico.

RIGODUNUM, in *Ancient Geography*, a town of Britain,

tain, in the country of the Brigantes, placed by Camden and Baxter at Ribchefter in Lancafhire; but Horfley prefers Manchefter or Warrington. See RIBCHESTER.

RIGOLL, or REGALS, a kind of mufical inftrument, confifting of feveral fticks bound together, only feparated by beads. It makes a tolerable harmony, being well ftruck with a ball at the end of a ftick.

Such is the account which Graffineau gives of this inftrument.

Skinner, upon the authority of an old Englifh dictionary, reprefents it as a clavichord, or clarichord; poffibly founding his opinion on the nature of the office of the tuner of the regals, who ftill fubfifts in the eftablifhment of the king's chapel at St. James's, and whofe bufinefs is to keep the organ of the chapel royal in tune; and not knowing that fuch wind inftruments as the organ need frequent tuning, as well as the clavichord and other ftringed inftruments.

Sir Henry Spelman derives the word *rigol* from the Italian *rigabello*, a mufical inftrument, anciently ufed in churches inftead of the organ.

Walther, in his defcription of the regal, makes it to be a reed-work in an organ, with metal and alfo wooden pipes, and bellows, adapted to it. And he adds, that the name of it is fuppofed to be owing to its having been prefented by the inventor to fome king.

From an account of the regal, ufed in Germany, and other parts of Europe, it appears to confift of pipes and keys on one fide, and the bellows and wind-cheft on the other.

We may add, that lord Bacon (Nat. Hift. cent. ii. § 102.) diftinguifhes between the regal and organ, in a manner which fhews them to be inftruments of the fame clafs. Upon the whole there is reafon to conclude, that the *regal*, or *rigol*, was a pneumatic, and not a ftringed inftrument.

Merfennus relates that the Flemings invented an inftrument, *les regales de bois*, confifting of feventeen cylindrical pieces of wood, decreafing gradually in length, fo as to produce a fucceffion of tones and femitones in the diatonic feries, which had keys, and was played on as a fpinnet; the hint of which, he fays, was taken from an inftrument in ufe among the Turks, confifting of twelve wooden cylinders, of different lengths, ftrung together, which, being fufpended, and ftruck with a ftick, having a ball at the end, produced mufic. Hawkins's Hift. Muf. vol. ii. p. 449. See REGAL.

RIGOMAGUS, in *Geography*, a town of Italy, in Liguria, at a fmall diftance N. of Afta.

RIGOR, in *Medicine*, a *fhivering*, or the flight convulfive *tremors*, attended by a fenfation of cold, which occur either from actual expofure to cold, or from that condition of the body which ufually precedes a paroxyfm of fever, or which, it fhould rather be faid, conftitutes one of the firft fymptoms of a febrile paroxyfm. (See FEVER.) There is often no abfolute diminution of the heat in the body, when this fenfation of cold, and even actual fhivering, with a difpofition to fit near a fire, or to be loaded with blankets, occur. It arifes, therefore, from fome peculiar affection of the brain and nervous fyftem, and not from actual deficiency of heat. This is farther proved by the circumftance, that a fimilar tremor, or *rigor*, is capable of being temporarily excited by certain impreffions upon the fenforium; as by certain fights, or even thoughts, that excite horror: whence, indeed, the word *horror* is applied by medical writers in nearly the fame fenfe with *rigor*.

Rigor, or chillinefs, precedes or commences the attack of almoft all febrile and inflammatory difeafes; whence the vulgar, miftaking the firft fymptom for the caufe, afcribe all thefe difeafes to the agency of *cold*, the operation of which they conceive to have been accomplifhed at the time when the *rigor* occurred. It takes place at the beginning of quinfey, pleurify, peripneumony, and all the organic inflammations; at the commencement of almoft all fevers; and at each fuch fucceffive paroxyfm or even exacerbation of intermittent, remittent, and hectic fevers: it conftitutes the moft ftriking feature, indeed, of the intermittent fever, which is hence called the *ague* by the common people, in contradiftinction from the *fever*, or hot fit, which enfues. The tremor and clattering of the teeth are often fo great, indeed, in the cold fit of an ague, as to fhake the bed and its furniture about the patient. It made even Cæfar tremble.

> " He had a fever when he was in Spain,
> And, when the fit was on him, I did mark
> How he did fhake: 'tis true, this god did fhake."
> Shakfpeare.

The rigor is a fymptom ftill more notorious in pathology, as having been the foundation of Dr. Cullen's whole theory of fever. That phyfician maintained, that the rigor, or *cold fit*, having been produced by the fedative influence of the common caufes of fever on the brain, became itfelf the caufe of the fucceeding *hot* and *fweating* ftages, by roufing the heart and arteries to greater actions, in order to throw back the load of blood into the extreme veffels, which had been driven to the centre by the conftriction of the latter, while the *rigor* lafted. The reader will find this doctrine ftated, and refuted, under the article FEVER, and the head *Cullenian Theory*. It is not difficult to fhew, refpecting this, as well as the vulgar opinion, that the *rigor*, like the heat, and the fweating, is one in the chain of *effects*, and not a *caufe* of the phenomena which enfue. But it would be equally difficult to explain the immediate caufe of any of them.

RIGOSA, in *Geography*, a town of Italy, in the department of the Serio; 3 miles N.N.W. of Bergamo.

RIGOURISTS, in *Ecclefiaftical Hiftory*. See JANSENISM.

RIGUSA, in *Ancient Geography*, a town of Spain, in the Tarragonenfis, belonging to the Carpetani. Ptolemy.

RILEY, JOHN, in *Biography*, a portrait painter, and the beft which England had produced prior to fir Jofhua Reynolds. He was born in London in 1646. After the death of Lely he obtained very confiderable efteem and employment. He painted the portraits of king Charles II., James II. and his queen, and was appointed by James ftate-painter. His ftyle is compofed from Vandyke and Lely, and his execution is free and mafterly, and bears an air of originality. He died in 1691, at the age of 45.

RILL, or RIVULET. See RIVER.

RILL, in *Agriculture*, a fmall runlet of water, moftly rifing on the fides of fmall hills or declivities. In many fituations they may be converted to ufeful purpofes in hufbandry, fuch as the irrigation of pafture or meadow lands that lie below their levels; the fupplying of grafs grounds with water, for the purpofes of live-ftock; and the affording it to towns and villages, in dry or other ſituations where it is ſcarce. See IRRIGATION, WATERING *of Land*, and the following article.

RILLS, *Artificial*, ſuch as have been formed or made by means of art. It has been remarked, that the practice of conſtructing rivulets of this ſort for ſupplying water is peculiar to a few diſtricts of this country, as Yorkſhire and weſt Devonſhire, in the latter of which they have been made uſe of time immemorial in bringing what, in the ſimple language of the diſtrict, is termed "pot-water" to the farm-houſes, and the hamlets of cottages in upland ſituations; an excellent expedient, which is ſuppoſed applicable in many other parts of the iſland, but which, except in the caſe of Yorkſhire, has hitherto been confined to that extreme part of the country.

And in forming theſe ſorts of rills in their original diſtrict, it is obſerved by Mr. Marſhall, that one which ſupplies the houſe with water, alſo a drinking-pool near the yard, and in the natural courſe of it conveying it through a ſtraw yard, a trough is placed acroſs it for the uſe of the yard cattle; and which has, likewiſe, been for a vaſt length of time led over ſome graſs land, which lies below the yards, on the principle of the float and drain. But that although this rill is ſeldom, if ever, dried up, leading it along the ſides of the valley, through upland incloſures, which are deſtitute of water for ſtock, and their value of courſe thereby much depreciated, does not appear to have been thought of. In the courſe of the ſummer of 1792, being deſirous to know if this rill could be carried through an intended ſuite of yards on the ſide of the valley, he took the level, and found not only that object to be attainable, but alſo that it might be led with eaſe into two waterleſs fields which lie above theſe yards; and, through them, into four or five more (equally in want of water for ſtock) ſituated beyond them. It is added that, in aſcertaining theſe facts, he made uſe of a maſon's long level inverted, a plummet-hole being previouſly cut in the head of the ſtandard; the crown of which being ſet upon the ground, the arms of the level were ſteadied by rods in the horizontal poſition; and a carpenter's rule held acroſs another rod, ſet up, at as great a diſtance as a clear ſight would admit of, and at a height upon the ſtaff equal to the height of the level. Finding this a moſt ſimple and perfect inſtrument, but difficult to adjuſt, by reaſon of its inſtability, he has ſince had a *frame-level* made on the ſame principle; namely, with a ſtraight edge, or top rail, anſwering to the baſe-board of the long level, with a broad piece falling down from the middle of it, anſwering to the ſtandard; and with two end-pieces or legs, to ſuperſede the uſe of the rods, together with a bottom rail, eight or nine inches from the ground, and with diagonal braces to keep the whole firm, and prevent the middle or plumb-line from getting out of the ſquare with the ſtraight edge of the top rail; which is ſeven or eight feet long, and the height about four feet. He thinks that half a rod long, and a quarter of a rod high, are eligible dimenſions when great accuracy is required. But a ſhorter length, as one-third of a rod, is more handy. And, as an improvement of the rule and rod, he has contrived a *croſs-ſtaff*; namely, a ſlip of thin deal, about five feet and a half long, with a croſs-piece about two feet long and three inches wide, fixed in the edge of it, at the exact height of the level; the top of the ſtaff riſing twelve or eighteen inches above the upper edge of the croſs-piece, that the hand of the perſon who holds it up may not interfere with the view. This croſs-piece ſhould be of white wood, as deal, or be painted white, that it may be more diſtinctly ſeen at a diſtance. With this implement the flowing level may be well aſcertained.

And it is obſerved that, in order to aſcertain the proper fall of a rill of this intention, he previouſly took the running level of the ancient floating *leat* of the meadow, and finding its fall irregular, he took it in two places where the variations were greateſt. In the firſt, the fall was twenty-ſeven inches in one hundred and ten feet; which is nearly one inch, or one foot of fall to fifty inches, or fifty feet, in length. In this part the current is in a degree rapid; the fall much too great for the general intention. The fall in one hundred and ten feet of the other part is barely ſix inches; which is only one meaſure of perpendicular height to two hundred and twenty of horizontal length. But in this part the motion is too ſluggiſh; the ſurface of the water is nearly ſmooth; barely dimpling; no ripple or agitation appears. The fall is evidently too little for a water courſe, in which there is not a conſtant ſtream. He has therefore fixed upon one meaſure in a hundred, as the proper fall of a water-courſe, into which water is occaſionally thrown for the purpoſes of watering lands, filling drinking-pools, ciſterns, and other ſimilar purpoſes. And in order to adjuſt the level to this deſcent, he meaſured one hundred feet in length, and having nicely aſcertained the *dead level*, he depreſſed the range of the top bar one foot below the upper edge of the croſs-piece of the ſtaff, and, while in that poſition, he marked the ſituation of the plumb-line on the face of the level, the plummet-hole being made wide for this purpoſe; thus fixing the flowing level. And with this deſcent, he has traced a line from an intended reſervoir, and from point to point, through the fields of one ſide of the farm, and finds that it reaches, even with this deſcent, within every field; and that three-fourths, or a larger proportion, of the ſurface are capable of being floated from this intended pool. With the view of ſeeing the actual motion of water falling one in a hundred, he has had fifty yards of the upper end of the line opened, and finds the current fully ſufficient; a lively rippling ſtream, more active, perhaps, than is neceſſary. But the leakage being the leſs the quicker the water moves, it may, he thinks, be ſafely concluded that one foot of fall in a hundred feet length is nearly the proper degree that is required.

And in the ſame caſe he has, by the ſame means, alſo found that, from a ſimilar reſervoir formed near the ſource of the rill, water might be conveyed to every field, and almoſt every acre of the oppoſite ſide of the farm, which is a matter of great conſequence. It is ſuggeſted, that the uſes of theſe reſervoirs will be thoſe of having in readineſs, during the ſummer months, when the rill is weak, a body of water to throw into drinking-pools, ciſterns, &c.; a weak current turned into a dry trench is abſorbed by its perforations and fiſſures, for ſome time, at leaſt, after it is turned in; whereas a body of water, ruſhing quickly along it, not only in part eſcapes abſorption, but tends to fill up the leaks; and, in winter, theſe reſervoirs will be uſeful in ſcouring the trenches, and in hoarding up bodies of water for the purpoſe of irrigation, or other ſimilar uſes. In the ſetting out of theſe rills, he has laid the head or upper end of each, from two to three feet below the intended ſurfaces of their reſpective reſervoirs, when full. Hence, by the means of a portcullis flood-gate, a body of water two or three feet deep, and the whole extent of the ſurfaces of the baſons, may be poured into the rills, faſter or ſlower, as may be requiſite. And in a ſubſequent minute it is ſtated, that difficulties were met with in conducting a rill through an open grove of trees, but which were overcome in the following manner; having, by means of the frame level and croſs, aſcertained the general deſcent, or flowing level, through the whole extent of the grove; and having, in this

operation,

operation, gained a general idea of the requiſite direction of the rill, by means of ſtakes placed at the ſeveral ſtations of the croſs-ſtaff, wherever clear views could be caught through the openings between the trees, the intermediate ſpaces between the ſtakes were traced by the eye, ſo as to endeavour to follow the natural level of the ground, without forming abrupt bends in the channel: parrying between the two. And that the ſuppoſed line being thus ſet out, the ſurface of the ground was cleared two or three feet wide on either ſide of it, from leaves and other incumbrances, and the top ſoil removed for manure; thus making a hollow pathway through the grove, four or five feet wide. The next operation was to level this pathway, which was likewiſe done by the eye, from ſtake to ſtake; paring off the protuberances, and caſting or wheeling them into the hollows to fill them up. Then in order to come at the true line, and to render the flowing level perfectly uniform, a narrow pathlet, the width of the ſpade, was formed on the upper ſide of the broad pathway. This pathlet was formed with the frame level in hand, ſinking trenches in the ſtill protuberating parts, and raiſing banklets in the hollows; thus fixing the exact flowing level at each level's length, and, at the ſame time, forming the face or lower ſide of it, in ſuch manner as to eaſe the bends, and give a ſmooth flowing line to the rill or runlet of the water. And further, in order to bring the buſineſs of forming the bed of the rill to a certainty, and thereby to render any further ſuperintendance unneceſſary, yet to prevent error in the execution, he formed a *gauge* for the labourers to work by; which conſiſted of a board, forming the ſegment of a circle; the chord or greateſt length being three feet, the greateſt depth twelve inches. This gives the dimenſions of the bed of the rill. To keep the bottom of it exactly true to the flowing level, ſo that the current ſtream may be perfectly uniform, it is fixed under a maſon's ſhort level; the end of one of the arms projecting three or four inches beyond one end of the gauge. And the trench being ſunk to nearly its proper depth, by the eye kept on the adjuſted margin, the projecting end of the level is placed on the ſame marginal guide, and the plummet-line being brought to the perpendicular, (and the baſe of the level of courſe rendered horizontal,) the bottom of the trench is finiſhed with certainty.

Upon having the water turned into the upper part of the trench thus formed, by two common labourers, who never before, perhaps, took a level in their hands, the current was found not only deſirable as to deſcent, but perfectly uniform, without alteration. And hence the practicability and certainty of this method of forming the channels of rills, as well as the eligibility of one meaſure in a hundred, for the deſcent or fall, are fully aſcertained. It is obſerved that the above dimenſions are the moſt proper for the part paſſing under trees, as being liable to fill up, by leaves and ſmall twigs; but in open land, liable to be trodden by cattle, four feet in width, and eight inches deep is better, the lower ſide being made broad and flatly convex to prevent treading in, being turfed over with the ſods removed.

But in reſpect to the Yorkſhire rills, the ſame writer remarks that the heights of the northern margin have neither ſprings nor rivulets (ſome very few inſtances excepted), nor any other natural waters than the brooks which wind at the bottom of the deep vallies that divide them, and the rivulets which generally run at the feet of the precipices that terminate them. That formerly theſe brooks and rivulets were the only reſources which the villages that are ſcattered on theſe heights had for water, both for the uſe of cattle and for domeſtic purpoſes. But that in proceſs of time wells were ſunk, but they are of ſuch a depth as to make the labour of raiſing the water little leſs than that of fetching it from a moderate diſtance. Of courſe that this kind of natural neceſſity has led to an expedient which, though not new in principle, is perhaps entirely ſo in ſimplicity of execution, and might be practiſed with great advantage in many ſimilar ſituations. For as the moorland mountains riſe with generally an eaſy aſcent, from the beds of the rivulets laſt-mentioned, to a height much exceeding that of the hills to be watered, frequently abounding with ſprings almoſt to their higheſt ſwells, theſe ſprings are collected and conducted by a narrow channel down the ſlope of the mountain ſides, and along the face of the precipice, until the ſummit be gained; the waters being thence conveyed to the place or places deſired. It is ſtated that, in planning an artificial rill, a level, and ſome little knowledge of the country, are, as has been ſeen, the requiſite guides. The ſurveyor begins at the place to which the water is required to be brought, and aſcertains the loweſt part of the brink of the precipice from which water can be conducted. The face of the precipice is traced in like manner; and, if neceſſary, the aſcent of the moorland hills, until ſprings, or their natural rills, can be commanded. And that if his level bring him to the bottom of the ſteep ſoon enough to catch the rivulet which runs at its foot, the work is readily completed. If not, he goes above its higheſt bend, generally to the head or higheſt part of the valley (between the heights and the moorlands), and winds along the ſide of the oppoſite ſwell to ſome more elevated ſource. And if, when he arrives on the moorland hills (or, by an obſervation from the top of the precipice,) he finds that nature does not furniſh the requiſite quantity of water high enough to give the neceſſary fall, the work is, of courſe, impracticable.

But in regard to the manner of executing an artificial rill in this part, an opening ſhallow channel, of a width proportioned to the quantity of water to be conducted, is the main operation. In making ſtagnant pools, it has been found that much art is neceſſary to make them retentive, but in forming the bed of a rill no ſuch art is requiſite. It is the nature of running waters to render the ſurface on which they run firm and retentive. Sand is, he believes, the chief material uſed in forming the channels of theſe rills; and this only in places where an open rock or other porous ſtratum is croſſed. But much depends on the quantity of fall and the quantity of water. If the fall be but little, and the quantity of water at the ſource be ſuch as not to admit of much waſte, great care is requiſite in forming the bed of the rill. The fall is therefore regulated in a great degree by the quality of the ground. On good ground the channel is nearly level. Over faulty ground the water runs with a current for the double purpoſe of getting quickly over it, and rendering its channel more retentive. The circumſtances from which injuries are produced in theſe rills are leaves in autumn and ſnows in winter. To remove the obſtructions which theſe not unfrequently cauſe, and to repair ſuch breaches as time will always make in the work of art, a ſuperintendant is neceſſary to every artificial rill.

And it is obſerved that the rill of Kirby moorſide is, he believes, the largeſt, and was the firſt which was brought upon theſe heights. This rill was brought to the villages of Gillimore and Fadmore near forty years ago; and has been extended to Kirby about thirty years, by Joſeph Ford, a ſelf-taught engineer of great ingenuity and ſome judgment; a man to whom the country owes much. Since the introduction of this, ſeveral others have been raiſed; and ſome few unſucceſsful attempts have been made; the channel was, in one inſtance, (that of Newton,) extended a conſiderable way before the impracticability of completing it

was

was difcovered; a piece of mifconduct which nothing but a want of accuracy in the ufe of the level can lead to. The mifcarriage, in this cafe, was not owing to a want of elevation in the fource, but to a depreffion of the channel at the foot of the fteep; the head of the valley (if fuch it may be called) being lower than the top of the precipice at the given point. This fhews the neceffity of tracing the entire channel with fufficient accuracy before any other expence is incurred. The mode of doing which has been fhewn above.

It is likewife further ftated, that in the cafe of Kirby the channel is raifed fomewhat by a bridge-like mound of earth thrown acrofs the crown of the valley. And that the fame mound ferves the purpofe of conducting another rill acrofs the fame difficult pafs; from whence the Kirby rill takes an eaftward, the rill of Welburn (applied principally to the watering of pafture grounds) a weftward direction.

Alfo in regard to the expence, it is ftated that the firft coft of the Kirby rill was not altogether one hundred pounds. The diftance about ten miles, watering (befides the town of Kirby) two villages and a line of cultivated waterlefs upland country about four miles in length. Befides the firft coft, which was raifed by fubfcription, a fuperintendant had ten pounds a-year for keeping it in repair and free from obftructions; which yearly falary is paid by the contributions of the perfons benefited; each being rated agreeably to the eftimated benefit received.

It may be noticed, that from the vaft advantages that have been derived from the conftruction of thefe forts of rivulets, in thefe few cafes of upland dry fituations, the attention of the land proprietor and farmer in other diftricts where there is a prevalent fcarcity of water, either for domeftic purpofes, or the ufe of cattle ftock, fhould be directed to the execution of them, on fuch cheap and beneficial plans as may be the moft convenient in the particular fituations. See Pond.

Thefe kinds of rills fhould, in all cafes where they are capable of it, be turned to the purpofe of watering land, as well as the ufes noticed above.

RILLE, in *Geography*, a town of France, in the department of the Maine and Loire; 9 miles E. of Baugé. —Alfo, a river of France, which runs into the Seine, fix miles below Quilbœuf.

RILLY, a town of France, in the department of the Marne; 6 miles S. of Reims.

RILSK, a town of Ruffia, in the government of Kurfk, on the Sem; 52 miles W.S.W. of Kurfk. N. lat. 51° 30′. E. long. 34° 54′.

RIM, in a watch or clock, the circumference or circular part of a wheel.

Rims, in *Ship Building*, compafs-pieces of timber, which form the quarter-galleries between the ftools.

Rims, a fkirting of elm-board round the upper fide of fhips' tops.

Rim, a caft-iron frame, in which the dropping-palls of the capftan traverfes, and palls, or counteracts the efforts of the capftan.

RIMA literally denotes a fiffure or chink. See Fissure, and Rhagades.

Hence, it is applied to feveral parts of the body, that bear a refemblance thereto; as *rima pudendi*, fiffura magna, the fame with vulva: and *rima laryngis*, the aperture of the larynx, called the *glottis*.

Rima is alfo ufed for a narrow aperture of a fmall cavity under the fornix, opening into the infundibulum; called alfo the third ventricle of the brain.

Rima, in *Geography*, a river of Hungary, which runs into the Theyffe, near Bolgar.

RIMAC, a river of Peru, which paffes by Lima, in a valley to which it gives name, on which Lima is built, and runs into the Pacific ocean, S. lat. 12°.

RIMAGIONE, a town of Genoa; 5 miles S.S.W. of Spezza.

RIMASZOMBAT, a town of Hungary; 14 miles E.S.E. of Altfol.

RIMBA, a province of Benguela, in Africa, on the banks of the Morano.

RIMBACH, a town of the duchy of Wurzburg; 3 miles S. of Volckach.

RIMBU, a town of Thibet; 71 miles W. of Laffa. N. lat. 30° 35′. E. long. 89° 50′.

RIME, in *Poetry*. See Rhyme.

Rime, in *Rural Economy*, a fort of hoary or white frofty appearance, fometimes on the ground in the autumnal winter and early fpring mornings.

RIMENANT, in *Geography*, a town of France, in the department of the Two Nethes; two miles E. of Malines.

RIMERS are moveable bars to fupport the fluices and over-falls in opening-weirs.

RIMFORSA, in *Geography*, a town of Sweden, in Weft Gothland; 17 miles S. of Linkoping.

RIMINI, a fea-port town of Italy, capital of the department of the Rubicon, late in the Romagna; formerly fituated on the fea, but the fea has for fome centuries receded to a diftance. The harbour on the river Marechia, on which the city is built, is now fo choaked up with fand, as fcarcely to admit of fmall barks. This city was once very flourifhing, but befides other calamities which have befallen it, it fuffered extremely from an earthquake in 1671. It is the fee of a bifhop, fuffragan of Ravenna. This is the ancient Ariminum, the firft town of which Cæfar took poffeffion, after paffing the Rubicon. In the market-place there is a kind of ftone pedeftal, with an infcription, declaring, that upon it Cæfar had ftood and harangued his army; but the authenticity of this is not afcertained to the fatisfaction of antiquaries. Befides this fuggeftum of doubtful antiquity, here is a triumphal arch, erected to the emperor Auguftus, and the remains of an amphitheatre. This city is faid to have been built 500 years earlier than Rome itfelf, and to have been made a colony in the year of Rome 483. It derived its name from the river Arminus, which wafhed its walls, and feparated the Via Flaminia from the Via Æmilia. Two councils were held here, one of orthodox bifhops, in the year 358, and another in the following year, of Arian prelates. Vitalien, governor of the city for the emperor Juftinian, defended it againft Vitiges, king of the Goths, with fuch vigour, as to oblige the Goths to raife the fiege. Some time after it became fubject to the Lombards; but when their laft king, Didier, was conquered and taken prifoner by Charles the Great, Rimini returned to the allegiance of the weftern emperors. The liberality of Otho III. conferred the dominion of it on the Malatefta family: at laft the Venetians gained poffeffion of it, and by a treaty with pope Julius II. gave it to the holy fee. The harbour at Rimini was formerly famous, being covered with marble, and of fuch extent, as to contain a confiderable fleet; but its mouth being filled up with fand, Sigifmond Pandolfo Malatefta deftroyed it, and with the marble ftones, raifed out of its ruins, built the Francifcan church, which is the fineft in Rimini; 57 miles S.E. of Bologna. N. lat. 44° 4′. E. long. 12° 38′.

RIMIS, a ſmall iſland in the Baltic, near the coaſt of Pomerania, N. lat. 54° 11′. E. long. 13° 26′.

RIMNIK. See RIBNIK.

RIMONT, a town of France, in the department of the Arriege; 8 miles W.N.W. of Taraſcon.

RIN, in *Rural Economy*, a provincial word uſed to ſignify brine.

RINÆUS, in *Anatomy*. See NASALIS.

RINALDI, ODERIC, in *Biography*, a learned Italian eccleſiaſtical hiſtorian in the 17th century, was a native of Treviſo, and entered the eſtabliſhment belonging to the prieſts of the congregation of the Oratory at Rome, of which Baronius had been a member. After the death of that cardinal, Rinaldi undertook the laborious taſk of continuing his "Eccleſiaſtical Annals," from the year 1198, with which the work of Baronius terminated, to the year 1564, when the council of Trent had been diſſolved. It abounds with many curious and valuable documents, taken from the archives at the Vatican, and other collections. It conſiſts of ten large volumes in folio, which made their appearance in Rome at different periods, from 1646 to 1677. Rinaldi publiſhed a ſufficiently copious abridgment, in Italian, of the whole annals, compiled both by Baronius and himſelf.

RINALDO DI CAPUA, an eminent Neapolitan compoſer, who flouriſhed in the middle of the laſt century, and whoſe ſtory is ſomewhat ſingular.

He was the natural ſon of a perſon of very high rank in that country, and at firſt only learned muſic as an accompliſhment; but being left by his father with only a ſmall fortune, which was ſoon diſſipated, he was forced to make it his profeſſion. He was but ſeventeen when he compoſed his firſt opera at Vienna.

In the courſe of a long life, Rinaldo experienced various viciſſitudes of fortune, ſometimes in vogue, ſometimes neglected. However, finding old age coming on, he collected together his principal works, ſuch as had been produced in the zenith of his fortune and fancy, thinking theſe would be a reſource in diſtreſsful times; thoſe times arrived; various misfortunes had happened to him and his family; when, behold! this reſource, this *ſole* reſource, the accumulated produce of his pen, had by a graceleſs ſon been ſold for waſte paper!

This compoſer, whoſe productions were, during many years, the delight of all Europe, in 1770 was reduced at Rome to the utmoſt indigence. Diogenes the Cynic was never more meanly clad through choice, than Rinaldo through neceſſity: a patched coat, and ſtockings that wanted to be patched or darned! We, having often received great pleaſure from his works, courted his acquaintance and converſation, which was very lively and intelligent; but though a good-natured man, his opinions were very ſingular and ſevere on his brother compoſers.

He thought they, at that time, "had nothing left within the reach of their invention to entitle them to reputation for novelty, but the refuſe of thouſands, which had been often tried and rejected, either as impracticable or diſpleaſing. The only chance which a compoſer has for introducing new modulation in ſongs, was in a ſhort ſecond part, (every ſerious ſong then ended with a *da capo*,) in order to *fright* the hearer back to the firſt, to which it ſerves as a foil, by making it comparatively beautiful." He included himſelf in the cenſure, and frankly confeſſed, that though he had written full as much as his neighbours, yet out of all his works, perhaps not above *one* new melody could be found, which had not been wire-drawn in different keys, and different meaſures, a thouſand and a thouſand times.

We ſubſcribed to theſe opinions at the time, till we heard Haydn's quartets and ſymphonies, Paeſiello's vocal compoſitions, and Mozart's latter works, vocal and inſtrumental.

Rinaldo cenſured, with great ſeverity, the noiſe and tumult of inſtruments in modern ſongs;—what would he ſay now to our double-drums and tromboni?

Rinaldo had the reputation at Rome of being the inventor of accompanied recitatives; but in ſearching for old compoſitions in the archives of San Girolamo della Carita, at Rome, we found an oratorio of Aleſſandro Scarlatti, which was compoſed at the latter end of the 17th century, before Rinaldo di Capua was born, and in which there are *accompanied recitatives*. But he did not, himſelf, pretend to the invention; all that he claimed was the being among the firſt who introduced ritornels, or interſtitial ſymphonies, in recitatives of ſtrong paſſion and diſtreſs, which expreſs or imitate what it would be ridiculous for the voice to attempt. There have been ſince many fine ſcenes of this kind in the works of Jomelli, Perez, Galuppi, Sarti, Piccini, Sacchini, and Paeſiello.

Rinaldo ſeems to have been a ſucceſsful compoſer from 1737 to 1758. His firſt ſerious opera at Rome was "Il Ciro Riconoſciuto," in 1737; and "Adriano in Siria," the laſt, in 1758.

A very fine air from "Vologeſo" was ſung by Monticelli in England, and printed by Walſh among the favourite ſongs in the opera of Gianguir,—"Nell' orror di notte oſcura,"—to which we refer as a ſpecimen of his ſerious ſtyle. Indeed the whole ſcene in that opera, beginning by the accompanied recitative, "Berenice, ove ſei?" and terminated by the air, "Ombra che pallida," is admirable, and a proof to what perfection dramatic muſic was brought in Italy fifty or ſixty years ago; and the curious will do well to procure a copy of this ſcene whenever they have an opportunity.

It has been ſaid, perhaps with ſome truth, that the ſcience of this compoſer was not equal to his genius; for being educated as a dilettante, he probably did not ſubmit to all the drudgery of dry ſtudy, which one intended for the profeſſion of muſic is obliged to undergo.

RINAR, a word uſed by the chemiſts, to expreſs filings of any thing.

RINAUR, in *Geography*, a town of Hindooſtan, in Myſore; 25 miles E. of Chinna Balabarum.

RINCADROLEAN POINT, a cape on the W. coaſt of Ireland, in the county of Kerry. N. lat. 52° 44′. W. long. 10° 13′.

RIND, a ſkin of any fruit that may be cut off, or pared. The outer coat of the cheſnut, ſet with prickles, is particularly called the *urchin-like rind*.

RIND is alſo uſed for the inner bark of trees; or that ſoft, whitiſh, juicy ſubſtance, adhering immediately to the wood.

Through this it is that the ſap has been ſuppoſed to return from the extremities of the branches to the root: the veſſels hereof are by ſome alſo ſuppoſed to do the office of arteries; whence Mr. Bradley calls them *arterial* veſſels. See PLANTS.

RIND, *Grafting in the*. See ENGRAFTING.

RIND-*Gall*, a damage a tree receives when young, ſo that the bark or rind grows in the inner ſubſtance of the tree.

RINDE, in *Geography*, a river of Hindooſtan, which runs into the Jumna, 15 miles S.E. of Corah.

RINDERA, in *Botany*. See Cynoglossum *lævigatum*, n. 14.

RINDGE, or Ringe, in *Geography*, a town of America, in the county of Chefhire, New Hampfhire, fituated on the Maffachufett's line, about 80 miles W. of Portfmouth, and 70 N.W. of Bolton. This town was incorporated in 1768, and contains 1226 inhabitants. This townfhip has 13 ponds of water of different fizes, in which are perch, trout, eels, &c. It has alfo, towards the northern part, a mine of ochre of a Spanifh brown. One half of the water of this town runs to the Merrimack, and the other to the Connecticut river.
